NIS servers store netgroup information in three separate maps called `netgroup`, `netgroup.byuser`, and `netgroup.byhost`. The purpose of the `netgroup.byuser` and `netgroup.byhost` maps is to speed up netgroup searches. ONTAP can perform netgroup-by-host searches on NIS servers for improved mount response times.

By default, LDAP directories do not have such a `netgroup.byhost` map like NIS servers. It is possible, though, with the help of third-party tools, to import a NIS `netgroup.byhost` map into LDAP directories to enable fast netgroup-by-host searches. If you have configured your LDAP environment to allow netgroup-by-host searches, you can configure the ONTAP LDAP client with the `netgroup.byhost` map name, DN, and search scope for faster netgroup-by-host searches.

Receiving the results for netgroup-by-host searches faster enables ONTAP to process export rules faster when NFS clients request access to exports. This reduces the chance of delayed access due to netgroup search latency issues.

Steps

1. Obtain the exact full distinguished name of the NIS netgroup.byhost map you imported into your LDAP directory.

The map DN can vary depending on the third-party tool you used for import. For best performance, you should specify the exact map DN.

2. Set the privilege level to advanced: `set -privilege advanced`

3. Enable netgroup-by-host searches in the LDAP client configuration of the storage virtual machine (SVM):

```
vserver services name-service ldap client modify -vserver vserver_name -client -config config_name -is-netgroup-byhost-enabled true -netgroup-byhost-dn netgroup-by-host_map_distinguished_name -netgroup-byhost-scope netgroup-by-host_search_scope
```

`-is-netgroup-byhost-enabled {true|false}` enables or disables netgroup-by-host search for LDAP directories. The default is `false`.

`-netgroup-byhost-dn netgroup-by-host_map_distinguished_name` specifies the distinguished name of the netgroup.byhost map in the LDAP directory. It overrides the base DN for netgroup-by-host searches. If you do not specify this parameter, ONTAP uses the base DN instead.

`-netgroup-byhost-scope {base|onelevel|subtree}` specifies the search scope for netgroup-by-host searches. If you do not specify this parameter, the default is `subtree`.

If the LDAP client configuration does not exist yet, you can enable netgroup-by-host searches by specifying these parameters when creating a new LDAP client configuration using the `vserver services name-service ldap client create` command.

Beginning with ONTAP 9.2, the field `-ldap-servers` replaces the field `-servers`. This new field can take either a hostname or an IP address for the LDAP server.

4. Return to the admin privilege level: `set -privilege admin`

Example

The following command modifies the existing LDAP client configuration named "ldap_corp" to enable netgroup-by-host searches using the netgroup.byhost map named "nisMapName="netgroup.byhost",dc=corp,dc=example,dc=com" and the default search scope subtree:

```
cluster1::>*> vserver services name-service ldap client modify -vserver vs1 -client-config ldap_corp -is-netgroup-byhost-enabled true -netgroup-byhost-dn nisMapName="netgroup.byhost",dc=corp,dc=example,dc=com
```

After you finish

The netgroup.byhost and netgroup maps in the directory must be kept in sync at all times to avoid client access issues.

[IETF RFC 5952: A Recommendation for IPv6 Address Text Representation](#)

Display LDAP statistics

Beginning with ONTAP 9.2, you can display LDAP statistics for storage virtual machines (SVMs) on a storage system to monitor the performance and diagnose issues.

What you'll need

- You must have configured an LDAP client on the SVM.
- You must have identified LDAP objects from which you can view data.

Step

1. View the performance data for counter objects:

```
statistics show
```

Examples

The following example shows the performance data for object `secd_external_service_op`:

```
cluster::*> statistics show -vserver vserverName -object
secd_external_service_op -instance "vserverName:LDAP (NIS & Name
Mapping):GetUserInfoFromName:1.1.1.1"

Object: secd_external_service_op
Instance: vserverName:LDAP (NIS & Name
Mapping):GetUserInfoFromName:1.1.1.1
Start-time: 4/13/2016 22:15:38
End-time: 4/13/2016 22:15:38
Scope: vserverName
Counter                Value
-----
instance_name           vserverName:LDAP (NIS & Name
Mapping):GetUserInfoFromName:
1.1.1.1
last_modified_time      1460610787
node_name               nodeName
num_not_found_responses 1
num_request_failures    1
num_requests_sent       1
num_responses_received  1
num_successful_responses 0
num_timeouts            0
operation               GetUserInfoFromName
process_name             secd
request_latency          52131us
```

Configure name mappings

Configure name mappings overview

ONTAP uses name mapping to map SMB identities to UNIX identities, Kerberos identities to UNIX identities, and UNIX identities to SMB identities. It needs this information to obtain user credentials and provide proper file access regardless of whether they are connecting from an NFS client or a SMB client.

There are two exceptions where you do not have to use name mapping:

- You configure a pure UNIX environment and do not plan to use SMB access or NTFS security style on volumes.
- You configure the default user to be used instead.

In this scenario, name mapping is not required because instead of mapping every individual client credential all client credentials are mapped to the same default user.

Note that you can use name mapping only for users, not for groups.

However, you can map a group of individual users to a specific user. For example, you can map all AD users that start or end with the word SALES to a specific UNIX user and to the user's UID.

How name mapping works

When ONTAP has to map credentials for a user, it first checks the local name mapping database and LDAP server for an existing mapping. Whether it checks one or both and in which order is determined by the name service configuration of the SVM.

- For Windows to UNIX mapping

If no mapping is found, ONTAP checks whether the lowercase Windows user name is a valid user name in the UNIX domain. If this does not work, it uses the default UNIX user provided that it is configured. If the default UNIX user is not configured and ONTAP cannot obtain a mapping this way either, mapping fails and an error is returned.

- For UNIX to Windows mapping

If no mapping is found, ONTAP tries to find a Windows account that matches the UNIX name in the SMB domain. If this does not work, it uses the default SMB user, provided that it is configured. If the default SMB user is not configured and ONTAP cannot obtain a mapping this way either, mapping fails and an error is returned.

Machine accounts are mapped to the specified default UNIX user by default. If no default UNIX user is specified, machine account mappings fail.

- Beginning with ONTAP 9.5, you can map machine accounts to users other than the default UNIX user.
- In ONTAP 9.4 and earlier, you cannot map machine accounts to other users.

Even if name mappings for machine accounts are defined, the mappings are ignored.

Multidomain searches for UNIX user to Windows user name mappings

ONTAP supports multidomain searches when mapping UNIX users to Windows users. All discovered trusted domains are searched for matches to the replacement pattern until a matching result is returned. Alternatively, you can configure a list of preferred trusted domains, which is used instead of the discovered trusted domain list and is searched in order until a matching result is returned.

How domain trusts affect UNIX user to Windows user name mapping searches

To understand how multidomain user name mapping works, you must understand how domain trusts work with ONTAP. Active Directory trust relationships with the SMB server's home domain can be a bidirectional trust or can be one of two types of unidirectional trusts, either an inbound trust or an outbound trust. The home domain is the domain to which the SMB server on the SVM belongs.

- *Bidirectional trust*

With bidirectional trusts, both domains trust each other. If the SMB server's home domain has a bidirectional trust with another domain, the home domain can authenticate and authorize a user belonging to the trusted domain and vice versa.

UNIX user to Windows user name mapping searches can be performed only on domains with bidirectional trusts between the home domain and the other domain.

- *Outbound trust*

With an outbound trust, the home domain trusts the other domain. In this case, the home domain can authenticate and authorize a user belonging to the outbound trusted domain.

A domain with an outbound trust with the home domain is *not* searched when performing UNIX user to Windows user name mapping searches.

- *Inbound trust*

With an inbound trust, the other domain trusts the SMB server's home domain. In this case, the home domain cannot authenticate or authorize a user belonging to the inbound trusted domain.

A domain with an inbound trust with the home domain is *not* searched when performing UNIX user to Windows user name mapping searches.

How wildcards (*) are used to configure multidomain searches for name mapping

Multidomain name mapping searches are facilitated by the use of wildcards in the domain section of the Windows user name. The following table illustrates how to use wildcards in the domain part of a name mapping entry to enable multidomain searches:

Pattern	Replacement	Result
root	*\\administrator	The UNIX user "root" is mapped to the user named "administrator". All trusted domains are searched in order until the first matching user named "administrator" is found.

Pattern	Replacement	Result
*	**	<p>Valid UNIX users are mapped to the corresponding Windows users. All trusted domains are searched in order until the first matching user with that name is found.</p> <p> The pattern ** is only valid for name mapping from UNIX to Windows, not the other way around.</p>

How multidomain name searches are performed

You can choose one of two methods for determining the list of trusted domains used for multidomain name searches:

- Use the automatically discovered bidirectional trust list compiled by ONTAP
- Use the preferred trusted domain list that you compile

If a UNIX user is mapped to a Windows user with a wildcard used for the domain section of the user name, the Windows user is looked up in all the trusted domains as follows:

- If a preferred trusted-domain list is configured, the mapped Windows user is looked up in this search list only, in order.
- If a preferred list of trusted domains is not configured, then the Windows user is looked up in all the bidirectional trusted domains of the home domain.
- If there are no bidirectionally trusted domains for the home domain, the user is looked up in the home domain.

If a UNIX user is mapped to a Windows user without a domain section in the user name, the Windows user is looked up in the home domain.

Name mapping conversion rules

An ONTAP system keeps a set of conversion rules for each SVM. Each rule consists of two pieces: a *pattern* and a *replacement*. Conversions start at the beginning of the appropriate list and perform a substitution based on the first matching rule. The pattern is a UNIX-style regular expression. The replacement is a string containing escape sequences representing subexpressions from the pattern, as in the UNIX sed program.

Create a name mapping

You can use the `vserver name-mapping create` command to create a name mapping. You use name mappings to enable Windows users to access UNIX security style volumes and the reverse.

About this task

For each SVM, ONTAP supports up to 12,500 name mappings for each direction.

Step

1. Create a name mapping:

```
vserver name-mapping create -vserver vserver_name -direction {krb-unix|win-unix|unix-win} -position integer -pattern text -replacement text
```

The `-pattern` and `-replacement` statements can be formulated as regular expressions. You can also use the `-replacement` statement to explicitly deny a mapping to the user by using the null replacement string " " (the space character). See the `vserver name-mapping create` man page for details.

When Windows-to-UNIX mappings are created, any SMB clients that have open connections to the ONTAP system at the time the new mappings are created must log out and log back in to see the new mappings.

Examples

The following command creates a name mapping on the SVM named vs1. The mapping is a mapping from UNIX to Windows at position 1 in the priority list. The mapping maps the UNIX user johnd to the Windows user ENG\JohnDoe.

```
vs1::> vserver name-mapping create -vserver vs1 -direction unix-win  
-position 1 -pattern johnd  
-replacement "ENG\\JohnDoe"
```

The following command creates another name mapping on the SVM named vs1. The mapping is a mapping from Windows to UNIX at position 1 in the priority list. Here the pattern and replacement include regular expressions. The mapping maps every CIFS user in the domain ENG to users in the LDAP domain associated with the SVM.

```
vs1::> vserver name-mapping create -vserver vs1 -direction win-unix  
-position 1 -pattern "ENG\\(.+)"  
-replacement "\1"
```

The following command creates another name mapping on the SVM named vs1. Here the pattern includes "\$" as an element in the Windows user name that must be escaped. The mapping maps the windows user ENG\john\$ops to UNIX user john_ops.

```
vs1::> vserver name-mapping create -direction win-unix -position 1  
-pattern ENG\\john\\$ops  
-replacement john_ops
```

Configure the default user

You can configure a default user to use if all other mapping attempts fail for a user, or if

you do not want to map individual users between UNIX and Windows. Alternatively, if you want authentication of non-mapped users to fail, you should not configure a default user.

About this task

For CIFS authentication, if you do not want to map each Windows user to an individual UNIX user, you can instead specify a default UNIX user.

For NFS authentication, if you do not want to map each UNIX user to an individual Windows user, you can instead specify a default Windows user.

Step

1. Perform one of the following actions:

If you want to...	Enter the following command...
Configure the default UNIX user	<code>vserver cifs options modify -default-unix-user user_name</code>
Configure the default Windows user	<code>vserver nfs modify -default-win-user user_name</code>

Commands for managing name mappings

There are specific ONTAP commands for managing name mappings.

If you want to...	Use this command...
Create a name mapping	<code>vserver name-mapping create</code>
Insert a name mapping at a specific position	<code>vserver name-mapping insert</code>
Display name mappings	<code>vserver name-mapping show</code>
Exchange the position of two name mappings	<code>vserver name-mapping swap</code>
 A swap is not allowed when name-mapping is configured with an ip-qualifier entry.	
Modify a name mapping	<code>vserver name-mapping modify</code>
Delete a name mapping	<code>vserver name-mapping delete</code>

Validate the correct name mapping	<pre>vserver security file-directory show-effective-permissions -vserver vs1 -win-user-name user1 -path / -share-name sh1</pre>
-----------------------------------	---

See the man page for each command for more information.

Enable access for Windows NFS clients

ONTAP supports file access from Windows NFSv3 clients. This means that clients running Windows operating systems with NFSv3 support can now access files on NFSv3 exports on the cluster. To successfully use this functionality, you must properly configure the storage virtual machine (SVM) and be aware of certain requirements and limitations.

What you'll need

NFSv3 must be enabled on the SVM.

About this task

By default, Windows NFSv3 client support is disabled.

Windows NFSv3 clients do not support the network status monitor (NSM) protocol. As a result, Windows NFSv3 client sessions might experience disruptions during storage failover and volume move operations.

Steps

1. Enable Windows NFSv3 client support:

```
vserver nfs modify -vserver vserver_name -v3-ms-dos-client enabled
```

2. On all SVMs that support Windows NFSv3 clients, disable the `-enable-ejukebox` and `-v3-connection-drop` parameters:

```
vserver nfs modify -vserver vserver_name -enable-ejukebox false -v3-connection-drop disabled
```

Windows NFSv3 clients can now mount exports on the storage system.

3. Ensure that each Windows NFSv3 client uses hard mounts by specifying the `-o mtype=hard` option.

This is required to ensure reliable mounts.

```
mount -o mtype=hard \\10.53.33.10\vol\vol1 z:\
```

Enable the display of NFS exports on NFS clients

NFS clients can use the `showmount -e` command to see a list of exports available from an ONTAP NFS server. This can help users identify the file system they want to mount.

Beginning with ONTAP 9.2, ONTAP allows NFS clients to view the export list by default. In earlier releases, the `showmount` option of the `vserver nfs modify` command must be enabled explicitly. For viewing the export list, NFSv3 should be enabled on the SVM.

Example

The following command shows the `showmount` feature on the SVM named vs1:

```
cluster1 : : > vserver nfs show -vserver vs1 -fields showmount
vserver showmount
-----
vs1    enabled
```

The following command executed on an NFS client displays the list of exports on an NFS server with the IP address 10.63.21.9:

```
showmount -e 10.63.21.9
Export list for 10.63.21.9:
/ unix          (everyone)
/ unix/unix1   (everyone)
/ unix/unix2   (everyone)
/               (everyone)
```

Manage file access using NFS

Enable or disable NFSv3

You can enable or disable NFSv3 by modifying the `-v3` option. This allows file access for clients using the NFSv3 protocol. By default, NFSv3 is enabled.

Step

1. Perform one of the following actions:

If you want to...	Enter the command...
Enable NFSv3	<code>vserver nfs modify -vserver vserver_name -v3 enabled</code>
Disable NFSv3	<code>vserver nfs modify -vserver vserver_name -v3 disabled</code>

Enable or disable NFSv4.0

You can enable or disable NFSv4.0 by modifying the `-v4.0` option. This allows file access for clients using the NFSv4.0 protocol. In ONTAP 9.9.1, NFSv4.0 is enabled by default; in earlier releases, it is disabled by default.

Step

1. Perform one of the following actions:

If you want to...	Enter the following command...
Enable NFSv4.0	<code>vserver nfs modify -vserver vserver_name -v4.0 enabled</code>

If you want to...	Enter the following command...
Disable NFSv4.0	vserver nfs modify -vserver vserver_name -v4.0 disabled

Enable or disable NFSv4.1

You can enable or disable NFSv4.1 by modifying the `-v4.1` option. This allows file access for clients using the NFSv4.1 protocol. In ONTAP 9.9.1, NFSv4.1 is enabled by default; in earlier releases, it is disabled by default.

Step

1. Perform one of the following actions:

If you want to...	Enter the following command...
Enable NFSv4.1	vserver nfs modify -vserver vserver_name -v4.1 enabled
Disable NFSv4.1	vserver nfs modify -vserver vserver_name -v4.1 disabled

Enable or disable pNFS

pNFS improves performance by allowing NFS clients to perform read/write operations on storage devices directly and in parallel, bypassing the NFS server as a potential bottleneck. To enable or disable pNFS (parallel NFS), you can modify the `-v4.1-pnfs` option.

If the ONTAP release is...	The pNFS default is...
9.8 or later	disabled
9.7 or earlier	enabled

What you'll need

NFSv4.1 support is required to be able to use pNFS.

If you want to enable pNFS, you must first disable NFS referrals. They cannot both be enabled at the same time.

If you use pNFS with Kerberos on SVMs, you must enable Kerberos on every LIF on the SVM.

Step

1. Perform one of the following actions:

If you want to...	Enter the command...
Enable pNFS	vserver nfs modify -vserver vserver_name -v4.1-pnfs enabled
Disable pNFS	vserver nfs modify -vserver vserver_name -v4.1-pnfs disabled

Control NFS access over TCP and UDP

You can enable or disable NFS access to storage virtual machines (SVMs) over TCP and UDP by modifying the `-tcp` and `-udp` parameters, respectively. This enables you to control whether NFS clients can access data over TCP or UDP in your environment.

About this task

These parameters only apply to NFS. They do not affect auxiliary protocols. For example, if NFS over TCP is disabled, mount operations over TCP still succeed. To completely block TCP or UDP traffic, you can use export policy rules.

You must turn off the SnapDiff RPC Server before you disable TCP for NFS to avoid a command failed error. You can disable TCP by using the command `vserver snapdiff-rpc-server off -vserver vserver name`.

Step

1. Perform one of the following actions:

If you want NFS access to be...	Enter the command...
Enabled over TCP	<code>vserver nfs modify -vserver vserver_name -tcp enabled</code>
Disabled over TCP	<code>vserver nfs modify -vserver vserver_name -tcp disabled</code>
Enabled over UDP	<code>vserver nfs modify -vserver vserver_name -udp enabled</code>
Disabled over UDP	<code>vserver nfs modify -vserver vserver_name -udp disabled</code>

Control NFS requests from nonreserved ports

You can reject NFS mount requests from nonreserved ports by enabling the `-mount-rootonly` option. To reject all NFS requests from nonreserved ports, you can enable the `-nfs-rootonly` option.

About this task

By default, the option `-mount-rootonly` is enabled.

By default, the option `-nfs-rootonly` is disabled.

These options do not apply to the NULL procedure.

Step

1. Perform one of the following actions:

If you want to...	Enter the command...
Allow NFS mount requests from nonreserved ports	<code>vserver nfs modify -vserver vserver_name -mount -rootonly disabled</code>
Reject NFS mount requests from nonreserved ports	<code>vserver nfs modify -vserver vserver_name -mount -rootonly enabled</code>
Allow all NFS requests from nonreserved ports	<code>vserver nfs modify -vserver vserver_name -nfs -rootonly disabled</code>
Reject all NFS requests from nonreserved ports	<code>vserver nfs modify -vserver vserver_name -nfs -rootonly enabled</code>

Handle NFS access to NTFS volumes or qtrees for unknown UNIX users

If ONTAP cannot identify UNIX users attempting to connect to volumes or qtrees with NTFS security style, it therefore cannot explicitly map the user to a Windows user. You can configure ONTAP to either deny access to such users for stricter security or map them to a default Windows user to ensure a minimum level of access for all users.

What you'll need

A default Windows user must be configured if you want to enable this option.

About this task

If a UNIX user tries to access volumes or qtrees with NTFS security style, the UNIX user must first be mapped to a Windows user so that ONTAP can properly evaluate the NTFS permissions. However, if ONTAP cannot look up the name of the UNIX user in the configured user information name service sources, it cannot explicitly map the UNIX user to a specific Windows user. You can decide how to handle such unknown UNIX users in the following ways:

- Deny access to unknown UNIX users.

This enforces stricter security by requiring explicit mapping for all UNIX users to gain access to NTFS volumes or qtrees.

- Map unknown UNIX users to a default Windows user.

This provides less security but more convenience by ensuring that all users get a minimum level of access to NTFS volumes or qtrees through a default Windows user.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Perform one of the following actions:

If you want the default Windows user for unknown UNIX users...	Enter the command...
Enabled	vserver nfs modify -vserver vserver_name -map -unknown-uid-to-default-windows-user enabled
Disabled	vserver nfs modify -vserver vserver_name -map -unknown-uid-to-default-windows-user disabled

3. Return to the admin privilege level:

```
set -privilege admin
```

Considerations for clients that mount NFS exports using a nonreserved port

The `-mount-rootonly` option must be disabled on a storage system that must support clients that mount NFS exports using a nonreserved port even when the user is logged in as root. Such clients include Hummingbird clients and Solaris NFS/IPv6 clients.

If the `-mount-rootonly` option is enabled, ONTAP does not allow NFS clients that use nonreserved ports, meaning ports with numbers higher than 1,023, to mount NFS exports.

Perform stricter access checking for netgroups by verifying domains

By default, ONTAP performs an additional verification when evaluating client access for a netgroup. The additional check ensures that the client's domain matches the domain configuration of the storage virtual machine (SVM). Otherwise, ONTAP denies client access.

About this task

When ONTAP evaluates export policy rules for client access and an export policy rule contains a netgroup, ONTAP must determine whether a client's IP address belongs to the netgroup. For this purpose, ONTAP converts the client's IP address to a host name using DNS and obtains a fully qualified domain name (FQDN).

If the netgroup file only lists a short name for the host and the short name for the host exists in multiple domains, it is possible for a client from a different domain to obtain access without this check.

To prevent this, ONTAP compares the domain that was returned from DNS for the host against the list of DNS domain names configured for the SVM. If it matches, access is allowed. If it does not match, access is denied.

This verification is enabled by default. You can manage it by modifying the `-netgroup-dns-domain-search` parameter, which is available at the advanced privilege level.

Steps

- Set the privilege level to advanced:

```
set -privilege advanced
```

- Perform the desired action:

If you want domain verification for netgroups to be...	Enter...
Enabled	vserver nfs modify -vserver vserver_name -netgroup-dns-domain-search enabled
Disabled	vserver nfs modify -vserver vserver_name -netgroup-dns-domain-search disabled

- Set the privilege level to admin:

```
set -privilege admin
```

Modify ports used for NFSv3 services

The NFS server on the storage system uses services such as mount daemon and Network Lock Manager to communicate with NFS clients over specific default network ports. In most NFS environments the default ports work correctly and do not require modification, but if you want to use different NFS network ports in your NFSv3 environment, you can do so.

What you'll need

Changing NFS ports on the storage system requires that all NFS clients reconnect to the system, so you should communicate this information to your users in advance of making the change.

About this task

You can set the ports used by the NFS mount daemon, Network Lock Manager, Network Status Monitor, and NFS quota daemon services for each storage virtual machine (SVM). The port number change affects NFS clients accessing data over both TCP and UDP.

Ports for NFSv4 and NFSv4.1 cannot be changed.

Steps

- Set the privilege level to advanced:

```
set -privilege advanced
```

- Disable access to NFS:

```
vserver nfs modify -vserver vserver_name -access false
```

- Set the NFS port for the specific NFS service:

```
vserver nfs modify -vserver vserver_namenfs_port_parameterport_number
```

NFS port parameter	Description	Default port
-mountd-port	NFS mount daemon	635
-nlm-port	Network Lock Manager	4045
-nsm-port	Network Status Monitor	4046
-rquotad-port	NFS quota daemon	4049

Besides the default port, the allowed range of port numbers is 1024 through 65535. Each NFS service must use a unique port.

4. Enable access to NFS:

```
vserver nfs modify -vserver vserver_name -access true
```

5. Use the network connections listening show command to verify the port number changes.

6. Return to the admin privilege level:

```
set -privilege admin
```

Example

The following commands set the NFS Mount Daemon port to 1113 on the SVM named vs1:

```

vs1::> set -privilege advanced
Warning: These advanced commands are potentially dangerous; use
        them only when directed to do so by NetApp personnel.
Do you want to continue? {y|n}: y

vs1::*> vserver nfs modify -vserver vs1 -access false

vs1::*> vserver nfs modify -vserver vs1 -mountd-port 1113

vs1::*> vserver nfs modify -vserver vs1 -access true

vs1::*> network connections listening show
Vserver Name      Interface Name:Local Port      Protocol/Service
-----
Node: cluster1-01
Cluster          cluster1-01_clus_1:7700      TCP/ctlopcp
vs1              data1:4046                      TCP/sm
vs1              data1:4046                      UDP/sm
vs1              data1:4045                      TCP/nlm-v4
vs1              data1:4045                      UDP/nlm-v4
vs1              data1:1113                      TCP/mount
vs1              data1:1113                      UDP/mount
...
.

vs1::*> set -privilege admin

```

Commands for managing NFS servers

There are specific ONTAP commands for managing NFS servers.

If you want to...	Use this command...
Create an NFS server	vserver nfs create
Display NFS servers	vserver nfs show
Modify an NFS server	vserver nfs modify
Delete an NFS server	vserver nfs delete

<p>Hide the .snapshot directory listing under NFSv3 mount points</p> <p> Explicit access to the .snapshot directory will still be allowed even if the option is enabled.</p>	<p>vserver nfs commands with the -v3-hide-snapshot option enabled</p>
---	---

See the man page for each command for more information.

Troubleshoot name service issues

When clients experience access failures due to name service issues, you can use the vserver services name-service getxxbyyy command family to manually perform various name service lookups and examine the details and results of the lookup to help with troubleshooting.

About this task

- For each command, you can specify the following:
 - Name of the node or storage virtual machine (SVM) to perform the lookup on.
This enables you to test name service lookups for a specific node or SVM to narrow the search for a potential name service configuration issue.
 - Whether to show the source used for the lookup.
This enables you to check whether the correct source was used.
- ONTAP selects the service for performing the lookup based on the configured name service switch order.
- These commands are available at the advanced privilege level.

Steps

1. Perform one of the following actions:

```

[cols="2*",options="header"]
=====
| To retrieve the...| Use the command...
a|
IP address of a host name
a|
`vserver services name-service getxxbyyy getaddrinfo`      `vserver

Verify name service connections

Beginning with ONTAP 9.2, you can check DNS and LDAP name servers to verify that they are connected to ONTAP. These commands are available at the admin privilege level.

About this task

You can check for a valid DNS or LDAP name service configuration on an as-needed basis using the name service configuration checker. This validation check can be initiated at the command line or in System Manager.

For DNS configurations, all servers are tested and need to be working for the configuration to be considered valid. For LDAP configurations, as long as any server is up, the configuration is valid. The name service commands apply the configuration checker unless the `skip-config-validation` field is true (the default is false).

Step

1. Use the appropriate command to check a name service configuration. The UI displays the status of the configured servers.

To check...	Use this command...
DNS configuration status	<code>vserver services name-service dns check</code>
LDAP configuration status	<code>vserver services name-service ldap check</code>

```
cluster1::> vserver services name-service dns check -vserver vs0
```

Vserver	Name Server	Status	Status Details
vs0	10.11.12.13	up	Response time (msec): 55
vs0	10.11.12.14	up	Response time (msec): 70
vs0	10.11.12.15	down	Connection refused.

```

cluster1::> vserver services name-service ldap check -vserver vs0

| Vserver: vs0
| Client Configuration Name: c1
| LDAP Status: up
| LDAP Status Details: Successfully connected to LDAP server
"10.11.12.13".

```

Configuration validation is successful if at least one of the configured servers (name-servers/ldap-servers) is reachable and providing the service. A warning is shown if some of the servers are not reachable.

Commands for managing name service switch entries

You can manage name service switch entries by creating, displaying, modifying, and deleting them.

If you want to...	Use this command...
Create a name service switch entry	vserver services name-service ns-switch create
Display name service switch entries	vserver services name-service ns-switch show
Modify a name service switch entry	vserver services name-service ns-switch modify
Delete a name service switch entry	vserver services name-service ns-switch delete

See the man page for each command for more information.

Commands for managing name mappings

There are specific ONTAP commands for managing name mappings.

If you want to...	Use this command...
Create a name mapping	vserver name-mapping create
Insert a name mapping at a specific position	vserver name-mapping insert
Display name mappings	vserver name-mapping show
Exchange the position of two name mappings	vserver name-mapping swap
 A swap is not allowed when name-mapping is configured with an ip-qualifier entry.	
Modify a name mapping	vserver name-mapping modify
Delete a name mapping	vserver name-mapping delete
Validate the correct name mapping	vserver security file-directory show-effective-permissions -vserver vs1 -win-user-name user1 -path / -share-name sh1

See the man page for each command for more information.

Commands for managing local UNIX users

There are specific ONTAP commands for managing local UNIX users.

If you want to...	Use this command...
Create a local UNIX user	vserver services name-service unix-user create
Load local UNIX users from a URI	vserver services name-service unix-user load-from-uri
Display local UNIX users	vserver services name-service unix-user show
Modify a local UNIX user	vserver services name-service unix-user modify
Delete a local UNIX user	vserver services name-service unix-user delete

See the man page for each command for more information.

Commands for managing local UNIX groups

There are specific ONTAP commands for managing local UNIX groups.

If you want to...	Use this command...
Create a local UNIX group	vserver services name-service unix-group create
Add a user to a local UNIX group	vserver services name-service unix-group adduser
Load local UNIX groups from a URI	vserver services name-service unix-group load-from-uri
Display local UNIX groups	vserver services name-service unix-group show
Modify a local UNIX group	vserver services name-service unix-group modify
Delete a user from a local UNIX group	vserver services name-service unix-group deluser
Delete a local UNIX group	vserver services name-service unix-group delete

See the man page for each command for more information.

Limits for local UNIX users, groups, and group members

ONTAP introduced limits for the maximum number of UNIX users and groups in the cluster, and commands to manage these limits. These limits can help avoid performance issues by preventing administrators from creating too many local UNIX users and groups in the cluster.

There is a limit for the combined number of local UNIX user groups and group members. There is a separate limit for local UNIX users. The limits are cluster-wide. Each of these new limits is set to a default value that you can modify up to a preassigned hard limit.

Database	Default limit	Hard limit
Local UNIX users	32,768	65,536
Local UNIX groups and group members	32,768	65,536

Manage limits for local UNIX users and groups

There are specific ONTAP commands for managing limits for local UNIX users and groups. Cluster administrators can use these commands to troubleshoot performance issues in the cluster believed to be related to excessive numbers of local UNIX users and groups.

About this task

These commands are available to the cluster administrator at the advanced privilege level.

Step

1. Perform one of the following actions:

If you want to...	Use the command...
Display information about local UNIX user limits	vserver services unix-user max-limit show
Display information about local UNIX group limits	vserver services unix-group max-limit show
Modify local UNIX user limits	vserver services unix-user max-limit modify
Modify local UNIX group limits	vserver services unix-group max-limit modify

See the man page for each command for more information.

Commands for managing local netgroups

You can manage local netgroups by loading them from a URI, verifying their status across nodes, displaying them, and deleting them.

If you want to...	Use the command...
-------------------	--------------------

Load netgroups from a URI	<code>vserver services name-service netgroup load</code>
Verify the status of netgroups across nodes	<code>vserver services name-service netgroup status</code> Available at the advanced privilege level and higher.
Display local netgroups	<code>vserver services name-service netgroup file show</code>
Delete a local netgroup	<code>vserver services name-service netgroup file delete</code>

See the man page for each command for more information.

Commands for managing NIS domain configurations

There are specific ONTAP commands for managing NIS domain configurations.

If you want to...	Use this command...
Create a NIS domain configuration	<code>vserver services name-service nis-domain create</code>
Display NIS domain configurations	<code>vserver services name-service nis-domain show</code>
Display binding status of a NIS domain configuration	<code>vserver services name-service nis-domain show-bound</code>
Display NIS statistics	<code>vserver services name-service nis-domain show-statistics</code> Available at the advanced privilege level and higher.
Clear NIS statistics	<code>vserver services name-service nis-domain clear-statistics</code> Available at the advanced privilege level and higher.
Modify a NIS domain configuration	<code>vserver services name-service nis-domain modify</code>
Delete a NIS domain configuration	<code>vserver services name-service nis-domain delete</code>
Enable caching for netgroup-by-host searches	<code>vserver services name-service nis-domain netgroup-database config modify</code> Available at the advanced privilege level and higher.

See the man page for each command for more information.

Commands for managing LDAP client configurations

There are specific ONTAP commands for managing LDAP client configurations.

SVM administrators cannot modify or delete LDAP client configurations that were created by cluster administrators.

If you want to...	Use this command...
Create an LDAP client configuration	vserver services name-service ldap client create
Display LDAP client configurations	vserver services name-service ldap client show
Modify an LDAP client configuration	vserver services name-service ldap client modify
Change the LDAP client BIND password	vserver services name-service ldap client modify-bind-password
Delete an LDAP client configuration	vserver services name-service ldap client delete

See the man page for each command for more information.

Commands for managing LDAP configurations

There are specific ONTAP commands for managing LDAP configurations.

If you want to...	Use this command...
Create an LDAP configuration	vserver services name-service ldap create
Display LDAP configurations	vserver services name-service ldap show
Modify an LDAP configuration	vserver services name-service ldap modify
Delete an LDAP configuration	vserver services name-service ldap delete

See the man page for each command for more information.

Commands for managing LDAP client schema templates

There are specific ONTAP commands for managing LDAP client schema templates.

SVM administrators cannot modify or delete LDAP client schemas that were created by cluster administrators.

If you want to...	Use this command...
Copy an existing LDAP schema template	vserver services name-service ldap client schema copy Available at the advanced privilege level and higher.

Display LDAP schema templates	vserver services name-service ldap client schema show
Modify an LDAP schema template	vserver services name-service ldap client schema modify Available at the advanced privilege level and higher.
Delete an LDAP schema template	vserver services name-service ldap client schema delete Available at the advanced privilege level and higher.

See the man page for each command for more information.

Commands for managing NFS Kerberos interface configurations

There are specific ONTAP commands for managing NFS Kerberos interface configurations.

If you want to...	Use this command...
Enable NFS Kerberos on a LIF	vserver nfs kerberos interface enable
Display NFS Kerberos interface configurations	vserver nfs kerberos interface show
Modify an NFS Kerberos interface configuration	vserver nfs kerberos interface modify
Disable NFS Kerberos on a LIF	vserver nfs kerberos interface disable

See the man page for each command for more information.

Commands for managing NFS Kerberos realm configurations

There are specific ONTAP commands for managing NFS Kerberos realm configurations.

If you want to...	Use this command...
Create an NFS Kerberos realm configuration	vserver nfs kerberos realm create
Display NFS Kerberos realm configurations	vserver nfs kerberos realm show
Modify an NFS Kerberos realm configuration	vserver nfs kerberos realm modify

If you want to...	Use this command...
Delete an NFS Kerberos realm configuration	vserver nfs kerberos realm delete

See the man page for each command for more information.

Commands for managing export policies

There are specific ONTAP commands for managing export policies.

If you want to...	Use this command...
Display information about export policies	vserver export-policy show
Rename an export policy	vserver export-policy rename
Copy an export policy	vserver export-policy copy
Delete an export policy	vserver export-policy delete

See the man page for each command for more information.

Commands for managing export rules

There are specific ONTAP commands for managing export rules.

If you want to...	Use this command...
Create an export rule	vserver export-policy rule create
Display information about export rules	vserver export-policy rule show
Modify an export rule	vserver export-policy rule modify
Delete an export rule	vserver export-policy rule delete

If you have configured multiple identical export rules matching different clients, be sure to keep them in sync when managing export rules.

See the man page for each command for more information.

Configure the NFS credential cache

Reasons for modifying the NFS credential cache time-to-live

ONTAP uses a credential cache to store information needed for user authentication for NFS export access to provide faster access and improve performance. You can configure how long information is stored in the credential cache to customize it for your environment.

There are several scenarios when modifying the NFS credential cache time-to-live (TTL) can help resolve issues. You should understand what these scenarios are as well as the consequences of making these modifications.

Reasons

Consider changing the default TTL under the following circumstances:

Issue	Remedial action
The name servers in your environment are experiencing performance degradation due to a high load of requests from ONTAP.	Increase the TTL for cached positive and negative credentials to reduce the number of requests from ONTAP to name servers.
The name server administrator made changes to allow access to NFS users that were previously denied.	Decrease the TTL for cached negative credentials to reduce the time NFS users have to wait for ONTAP to request fresh credentials from external name servers so they can get access.
The name server administrator made changes to deny access to NFS users that were previously allowed.	Reduce the TTL for cached positive credentials to reduce the time before ONTAP requests fresh credentials from external name servers so the NFS users are now denied access.

Consequences

You can modify the length of time individually for caching positive and negative credentials. However, you should be aware of both the advantages and disadvantages of doing so.

If you...	The advantage is...	The disadvantage is...
Increase the positive credential cache time	ONTAP sends requests for credentials to name servers less frequently, reducing the load on name servers.	It takes longer to deny access to NFS users that previously were allowed access but are not anymore.
Decrease the positive credential cache time	It takes less time to deny access to NFS users that previously were allowed access but are not anymore.	ONTAP sends requests for credentials to name servers more frequently, increasing the load on name servers.

If you...	The advantage is...	The disadvantage is...
Increase the negative credential cache time	ONTAP sends requests for credentials to name servers less frequently, reducing the load on name servers.	It takes longer to grant access to NFS users that previously were not allowed access but are now.
Decrease the negative credential cache time	It takes less time to grant access to NFS users that previously were not allowed access but are now.	ONTAP sends requests for credentials to name servers more frequently, increasing the load on name servers.

Configure the time-to-live for cached NFS user credentials

You can configure the length of time that ONTAP stores credentials for NFS users in its internal cache (time-to-live, or TTL) by modifying the NFS server of the storage virtual machine (SVM). This enables you to alleviate certain issues related to high load on name servers or changes in credentials affecting NFS user access.

About this task

These parameters are available at the advanced privilege level.

Steps

- Set the privilege level to advanced:

```
set -privilege advanced
```

- Perform the desired action:

If you want to modify the TTL for cached...	Use the command...
Positive credentials	<pre>vserver nfs modify -vserver vserver_name -cached-cred-positive-ttl time_to_live</pre> <p>The TTL is measured in milliseconds. The default is 24 hours (86,400,000 milliseconds). The allowed range for this value is 1 minute (60000 milliseconds) through 7 days (604,800,000 milliseconds).</p>
Negative credentials	<pre>vserver nfs modify -vserver vserver_name -cached-cred-negative-ttl time_to_live</pre> <p>The TTL is measured in milliseconds. The default is 2 hours (7,200,000 milliseconds). The allowed range for this value is 1 minute (60000 milliseconds) through 7 days (604,800,000 milliseconds).</p>

- Return to the admin privilege level:

```
set -privilege admin
```

Manage export policy caches

Flush export policy caches

ONTAP uses several export policy caches to store information related to export policies for faster access. Flushing export policy caches manually (`vserver export-policy cache flush`) removes potentially outdated information and forces ONTAP to retrieve current information from the appropriate external resources. This can help resolve a variety of issues related to client access to NFS exports.

About this task

Export policy cache information might be outdated due to the following reasons:

- A recent change to export policy rules
- A recent change to host name records in name servers
- A recent change to netgroup entries in name servers
- Recovering from a network outage that prevented netgroups from being fully loaded

Steps

1. If you do not have name service cache enabled, perform one of the following actions in advance privilege mode:

If you want to flush...	Enter the command...
All export policy caches (except for showmount)	<code>vserver export-policy cache flush -vserver vserver_name</code>
The export policy rules access cache	<code>vserver export-policy cache flush -vserver vserver_name -cache access</code> You can include the optional <code>-node</code> parameter to specify the node on which you want to flush the access cache.
The host name cache	<code>vserver export-policy cache flush -vserver vserver_name -cache host</code>
The netgroup cache	<code>vserver export-policy cache flush -vserver vserver_name -cache netgroup</code> Processing of netgroups is resource intensive. You should only flush the netgroup cache if you are trying to resolve a client access issue that is caused by a stale netgroup.
The showmount cache	<code>vserver export-policy cache flush -vserver vserver_name -cache showmount</code>

2. If name service cache is enabled, perform one of the following actions:

If you want to flush...	Enter the command...
The export policy rules access cache	vserver export-policy cache flush -vserver vserver_name -cache access You can include the optional -node parameter to specify the node on which you want to flush the access cache.
The host name cache	vserver services name-service cache hosts forward-lookup delete-all
The netgroup cache	vserver services name-service cache netgroups ip-to-netgroup delete-all vserver services name-service cache netgroups members delete-all Processing of netgroups is resource intensive. You should only flush the netgroup cache if you are trying to resolve a client access issue that is caused by a stale netgroup.
The showmount cache	vserver export-policy cache flush -vserver vserver_name -cache showmount

Display the export policy netgroup queue and cache

ONTAP uses the netgroup queue when importing and resolving netgroups and it uses the netgroup cache to store the resulting information. When troubleshooting export policy netgroup related issues, you can use the `vserver export-policy netgroup queue show` and `vserver export-policy netgroup cache show` commands to display the status of the netgroup queue and the contents of the netgroup cache.

Step

1. Perform one of the following actions:

To display the export policy netgroup...	Enter the command...
Queue	<code>vserver export-policy netgroup queue show</code>
Cache	<code>vserver export-policy netgroup cache show -vserver vserver_name</code>

See the man page for each command for more information.

Check whether a client IP address is a member of a netgroup

When troubleshooting NFS client access issues related to netgroups, you can use the `vserver export-policy netgroup check-membership` command to help determine whether a client IP is a member of a certain netgroup.

About this task

Checking netgroup membership enables you to determine whether ONTAP is aware that a client is or is not member of a netgroup. It also lets you know whether the ONTAP netgroup cache is in a transient state while refreshing netgroup information. This information can help you understand why a client might be unexpectedly granted or denied access.

Step

1. Check the netgroup membership of a client IP address: `vserver export-policy netgroup check-membership -vserver vserver_name -netgroup netgroup_name -client-ip client_ip`

The command can return the following results:

- The client is a member of the netgroup.

This was confirmed through a reverse lookup scan or a netgroup-by-host search.

- The client is a member of the netgroup.

It was found in the ONTAP netgroup cache.

- The client is not a member of the netgroup.
- The membership of the client cannot yet be determined because ONTAP is currently refreshing the netgroup cache.

Until this is done, membership cannot be explicitly ruled in or out. Use the `vserver export-policy netgroup queue show` command to monitor the loading of the netgroup and retry the check after it is finished.

Example

The following example checks whether a client with the IP address 172.17.16.72 is a member of the netgroup mercury on the SVM vs1:

```
cluster1::> vserver export-policy netgroup check-membership -vserver vs1  
-netgroup mercury -client-ip 172.17.16.72
```

Optimize access cache performance

You can configure several parameters to optimize the access cache and find the right balance between performance and how current the information stored in the access cache is.

About this task

When you configure the access cache refresh periods, keep the following in mind:

- Higher values mean entries stay longer in the access cache.

The advantage is better performance because ONTAP spends less resources on refreshing access cache entries. The disadvantage is that if export policy rules change and access cache entries become stale as a result, it takes longer to update them. As a result, clients that should get access might get denied, and clients that should get denied might get access.

- Lower values mean ONTAP refreshes access cache entries more often.

The advantage is that entries are more current and clients are more likely to be correctly granted or denied access. The disadvantage is a decrease in performance because ONTAP spends more resources refreshing access cache entries.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Perform the desired action:

To modify the...	Enter...
Refresh period for positive entries	vserver export-policy access-cache config modify-all-vservers -refresh -period-positive timeout_value
Refresh period for negative entries	vserver export-policy access-cache config modify-all-vservers -refresh -period-negative timeout_value
Timeout period for old entries	vserver export-policy access-cache config modify-all-vservers -harvest -timeout timeout_value

3. Verify the new parameter settings:

```
vserver export-policy access-cache config show-all-vservers
```

4. Return to the admin privilege level:

```
set -privilege admin
```

Manage file locks

About file locking between protocols

File locking is a method used by client applications to prevent a user from accessing a file previously opened by another user. How ONTAP locks files depends on the protocol of the client.

If the client is an NFS client, locks are advisory; if the client is an SMB client, locks are mandatory.

Because of differences between the NFS and SMB file locks, an NFS client might fail to access a file previously opened by an SMB application.

The following occurs when an NFS client attempts to access a file locked by an SMB application:

- In mixed or NTFS volumes, file manipulation operations such as `rm`, `rmdir`, and `mv` can cause the NFS application to fail.
- NFS read and write operations are denied by SMB deny-read and deny-write open modes, respectively.
- NFS write operations fail when the written range of the file is locked with an exclusive SMB bytelock.

In UNIX security-style volumes, NFS unlink and rename operations ignore SMB lock state and allow access to the file. All other NFS operations on UNIX security-style volumes honor SMB lock state.

How ONTAP treats read-only bits

The read-only bit is set on a file-by-file basis to reflect whether a file is writable (disabled) or read-only (enabled).

SMB clients that use Windows can set a per-file read-only bit. NFS clients do not set a per-file read-only bit because NFS clients do not have any protocol operations that use a per-file read-only bit.

ONTAP can set a read-only bit on a file when an SMB client that uses Windows creates that file. ONTAP can also set a read-only bit when a file is shared between NFS clients and SMB clients. Some software, when used by NFS clients and SMB clients, requires the read-only bit to be enabled.

For ONTAP to keep the appropriate read and write permissions on a file shared between NFS clients and SMB clients, it treats the read-only bit according to the following rules:

- NFS treats any file with the read-only bit enabled as if it has no write permission bits enabled.
- If an NFS client disables all write permission bits and at least one of those bits had previously been enabled, ONTAP enables the read-only bit for that file.
- If an NFS client enables any write permission bit, ONTAP disables the read-only bit for that file.
- If the read-only bit for a file is enabled and an NFS client attempts to discover permissions for the file, the permission bits for the file are not sent to the NFS client; instead, ONTAP sends the permission bits to the NFS client with the write permission bits masked.
- If the read-only bit for a file is enabled and an SMB client disables the read-only bit, ONTAP enables the owner's write permission bit for the file.
- Files with the read-only bit enabled are writable only by root.

Changes to file permissions take effect immediately on SMB clients, but might not take effect immediately on NFS clients if the NFS client enables attribute caching.

How ONTAP differs from Windows on handling locks on share path components

Unlike Windows, ONTAP does not lock each component of the path to an open file while the file is open. This behavior also affects SMB share paths.

Because ONTAP does not lock each component of the path, it is possible to rename a path component above the open file or share, which can cause problems for certain applications, or can cause the share path in the

SMB configuration to be invalid. This can cause the share to be inaccessible.

To avoid issues caused by renaming path components, you can apply security settings that prevent users or applications from renaming critical directories.

Display information about locks

You can display information about the current file locks, including what types of locks are held and what the lock state is, details about byte-range locks, sharelock modes, delegation locks, and opportunistic locks, and whether locks are opened with durable or persistent handles.

About this task

The client IP address cannot be displayed for locks established through NFSv4 or NFSv4.1.

By default, the command displays information about all locks. You can use command parameters to display information about locks for a specific storage virtual machine (SVM) or to filter the command's output by other criteria.

The `vserver locks show` command displays information about four types of locks:

- Byte-range locks, which lock only a portion of a file.
- Share locks, which lock open files.
- Opportunistic locks, which control client-side caching over SMB.
- Delegations, which control client-side caching over NFSv4.x.

By specifying optional parameters, you can determine important information about each lock type. See the man page for the command for more information.

Step

1. Display information about locks by using the `vserver locks show` command.

Examples

The following example displays summary information for an NFSv4 lock on a file with the path `/vol1/file1`. The sharelock access mode is `write-deny_none`, and the lock was granted with write delegation:

```
cluster1::> vserver locks show

Vserver: vs0
Volume  Object Path          LIF      Protocol  Lock Type  Client
-----  -----  -----
-----  -----
vol1    /vol1/file1          lif1     nfsv4    share-level -
                           Sharelock Mode: write-deny_none
                                         delegation -
                           Delegation Type: write
```

The following example displays detailed oplock and sharelock information about the SMB lock on a file with the

path /data2/data2_2/intro.pptx. A durable handle is granted on the file with a share lock access mode of write-deny_none to a client with an IP address of 10.3.1.3. A lease oplock is granted with a batch oplock level:

```
cluster1::> vserver locks show -instance -path /data2/data2_2/intro.pptx

          Vserver: vs1
          Volume: data2_2
Logical Interface: lif2
          Object Path: /data2/data2_2/intro.pptx
          Lock UUID: 553cf484-7030-4998-88d3-1125adbba0b7

```

Breaking locks

When file locks are preventing client access to files, you can display information about currently held locks, and then break specific locks. Examples of scenarios in which you might need to break locks include debugging applications.

About this task

The `vserver locks break` command is available only at the advanced privilege level and higher. The man page for the command contains detailed information.

Steps

1. To find the information you need to break a lock, use the `vserver locks show` command.

The man page for the command contains detailed information.

2. Set the privilege level to advanced:

```
set -privilege advanced
```

3. Perform one of the following actions:

If you want to break a lock by specifying...	Enter the command...
The SVM name, volume name, LIF name, and file path	<code>vserver locks break -vserver vserver_name -volume volume_name -path path -lif lif</code>
The lock ID	<code>vserver locks break -lockid UUID</code>

4. Return to the admin privilege level:

```
set -privilege admin
```

How FPolicy first-read and first-write filters work with NFS

NFS clients experience high response time during high traffic of read/write requests when

the FPolicy is enabled using an external FPolicy server with read/write operations as monitored events. For NFS clients, the use of first-read and first-write filters in the FPolicy reduces the number of FPolicy notifications and improves performance.

In NFS, the client does I/O on a file by fetching its handle. This handle might remain valid across reboots of the server and the client. Therefore, the client is free to cache the handle and send requests on it without retrieving handles again. In a regular session, lots of reads/write requests are sent to the file server. If notifications are generated for all these requests, it might result in the following issues:

- A larger load due to additional notification processing, and higher response time.
- A large number of notifications being sent to the FPolicy server even though the server unaffected by all of the notifications.

After receiving the first read/write request from a client for a particular file, a cache entry is created and the read/write count is incremented. This request is marked as the first-read/write operation, and an FPolicy event is generated. Before you plan and create your FPolicy filters for an NFS client, you should understand the basics of how FPolicy filters work.

- First-read: Filters the client read requests for first-read.

When this filter is used for NFS events, the `-file-session-io-grouping-count` and `-file-session-io-grouping-duration` settings determine the first-read request for which FPolicy is processed.

- First-write: Filters the client write requests for first-write.

When this filter is used for NFS events, the `-file-session-io-grouping-count` and `-file-session-io-grouping-duration` settings determine the first-write request for which FPolicy is processed.

The following options are added in NFS servers database.

```
file-session-io-grouping-count: Number of I/O Ops on a File to Be Clubbed  
and Considered as One Session  
for Event Generation  
file-session-io-grouping-duration: Duration for Which I/O Ops on a File to  
Be Clubbed and Considered as  
One Session for Event Generation
```

Modify the NFSv4.1 server implementation ID

The NFSv4.1 protocol includes a server implementation ID that documents the server domain, name, and date. You can modify the server implementation ID default values. Changing the default values can be useful, for example, when gathering usage statistics or troubleshooting interoperability issues. For more information, see RFC 5661.

About this task

The default values for the three options are as follows:

Option	Option name	Default value
NFSv4.1 Implementation ID Domain	-v4.1-implementation-domain	netapp.com
NFSv4.1 Implementation ID Name	-v4.1-implementation-name	Cluster version name
NFSv4.1 Implementation ID Date	-v4.1-implementation-date	Cluster version date

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Perform one of the following actions:

If you want to modify the NFSv4.1 implementation ID...	Enter the command...
Domain	vserver nfs modify -v4.1-implementation-domain domain
Name	vserver nfs modify -v4.1-implementation-name name
Date	vserver nfs modify -v4.1-implementation-date date

3. Return to the admin privilege level:

```
set -privilege admin
```

Manage NFSv4 ACLs

Benefits of enabling NFSv4 ACLs

There are many benefits to enabling NFSv4 ACLs.

The benefits of enabling NFSv4 ACLs include the following:

- Finer-grained control of user access for files and directories
- Better NFS security
- Improved interoperability with CIFS
- Removal of the NFS limitation of 16 groups per user

How NFSv4 ACLs work

A client using NFSv4 ACLs can set and view ACLs on files and directories on the system. When a new file or subdirectory is created in a directory that has an ACL, the new file or subdirectory inherits all ACL Entries (ACEs) in the ACL that have been tagged with the appropriate inheritance flags.

When a file or directory is created as the result of an NFSv4 request, the ACL on the resulting file or directory depends on whether the file creation request includes an ACL or only standard UNIX file access permissions, and whether the parent directory has an ACL:

- If the request includes an ACL, that ACL is used.
- If the request includes only standard UNIX file access permissions but the parent directory has an ACL, the ACEs in the parent directory's ACL are inherited by the new file or directory as long as the ACEs have been tagged with the appropriate inheritance flags.

A parent ACL is inherited even if `-v4.0-acl` is set to `off`.

- If the request includes only standard UNIX file access permissions and the parent directory does not have an ACL, the client file mode is used to set standard UNIX file access permissions.
- If the request includes only standard UNIX file access permissions and the parent directory has a non-inheritable ACL, the new object is created only with mode bits.

If the `-chown-mode` parameter has been set to `restricted` with commands in the `vserver nfs` or `vserver export-policy` rule families, file ownership can be changed by the superuser only, even if the on-disk permissions set with NFSv4 ACLs allow a non-root user to change the file ownership. For more information, see the relevant man pages.

Enable or disable modification of NFSv4 ACLs

When ONTAP receives a `chmod` command for a file or directory with an ACL, by default the ACL is retained and modified to reflect the mode bit change. You can disable the `-v4-acl-preserve` parameter to change the behavior if you want the ACL to be dropped instead.

About this task

When using unified security style, this parameter also specifies whether NTFS file permissions are preserved or dropped when a client sends a `chmod`, `chgroup`, or `chown` command for a file or directory.

The default for this parameter is enabled.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Perform one of the following actions:

If you want to...	Enter the following command...
If you want to...	Enter the following command...

Enable retention and modification of existing NFSv4 ACLs (default)	vserver nfs modify -vserver vserver_name -v4-acl -preserve enabled
Disable retention and drop NFSv4 ACLs when changing mode bits	vserver nfs modify -vserver vserver_name -v4-acl -preserve disabled

3. Return to the admin privilege level:

```
set -privilege admin
```

How ONTAP uses NFSv4 ACLs to determine whether it can delete a file

To determine whether it can delete a file, ONTAP uses a combination of the file's DELETE bit, and the containing directory's DELETE_CHILD bit. For more information, see the NFS 4.1 RFC 5661.

Enable or disable NFSv4 ACLs

To enable or disable NFSv4 ACLs, you can modify the `-v4.0-acl` and `-v4.1-acl` options. These options are disabled by default.

About this task

The `-v4.0-acl` or `-v4.1-acl` option controls the setting and viewing of NFSv4 ACLs; it does not control enforcement of these ACLs for access checking.

Step

1. Perform one of the following actions:

If you want to...	Then...
Enable NFSv4.0 ACLs	Enter the following command: <pre>vserver nfs modify -vserver vserver_name -v4.0-acl enabled</pre>
Disable NFSv4.0 ACLs	Enter the following command: <pre>vserver nfs modify -vserver vserver_name -v4.0-acl disabled</pre>
Enable NFSv4.1 ACLs	Enter the following command: <pre>vserver nfs modify -vserver vserver_name -v4.1-acl enabled</pre>

<p>Disable NFSv4.1 ACLs</p>	<p>Enter the following command:</p> <pre>vserver nfs modify -vserver vserver_name -v4.1-acl disabled</pre>
-----------------------------	--

Modify the maximum ACE limit for NFSv4 ACLs

You can modify the maximum number of allowed ACEs for each NFSv4 ACL by modifying the parameter `-v4-acl-max-aces`. By default, the limit is set to 400 ACEs for each ACL. Increasing this limit can help ensure successful migration of data with ACLs containing over 400 ACEs to storage systems running ONTAP.

About this task

Increasing this limit might impact performance for clients accessing files with NFSv4 ACLs.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Modify the maximum ACE limit for NFSv4 ACLs:

```
vserver nfs modify -v4-acl-max-aces max_ace_limit
```

The valid range of

`max_ace_limit` is 192 to 1024.

3. Return to the admin privilege level:

```
set -privilege admin
```

Manage NFSv4 file delegations

Enable or disable NFSv4 read file delegations

To enable or disable NFSv4 read file delegations, you can modify the `-v4.0-read-delegation` or `-v4.1-read-delegation` option. By enabling read file delegations, you can eliminate much of the message overhead associated with the opening and closing of files.

About this task

By default, read file delegations are disabled.

The disadvantage of enabling read file delegations is that the server and its clients must recover delegations after the server reboots or restarts, a client reboots or restarts, or a network partition occurs.

Step

1. Perform one of the following actions:

If you want to...	Then...
Enable NFSv4 read file delegations	Enter the following command: vserver nfs modify -vserver vserver_name -v4.0 -read-delegation enabled
Enable NFSv4.1 read file delegations	Enter the following command: + vserver nfs modify -vserver vserver_name -v4.1 -read-delegation enabled
Disable NFSv4 read file delegations	Enter the following command: vserver nfs modify -vserver vserver_name -v4.0 -read-delegation disabled
Disable NFSv4.1 read file delegations	Enter the following command: vserver nfs modify -vserver vserver_name -v4.1 -read-delegation disabled

Result

The file delegation options take effect as soon as they are changed. There is no need to reboot or restart NFS.

Enable or disable NFSv4 write file delegations

To enable or disable write file delegations, you can modify the -v4.0-write-delegation or -v4.1-write-delegation option. By enabling write file delegations, you can eliminate much of the message overhead associated with file and record locking in addition to opening and closing of files.

About this task

By default, write file delegations are disabled.

The disadvantage of enabling write file delegations is that the server and its clients must perform additional tasks to recover delegations after the server reboots or restarts, a client reboots or restarts, or a network partition occurs.

Step

1. Perform one of the following actions:

If you want to...	Then...
Enable NFSv4 write file delegations	Enter the following command: vserver nfs modify -vserver vserver_name -v4.0 -write-delegation enabled

If you want to...	Then...
Enable NFSv4.1 write file delegations	Enter the following command: vserver nfs modify -vserver vserver_name -v4.1 -write-delegation enabled
Disable NFSv4 write file delegations	Enter the following command: vserver nfs modify -vserver vserver_name -v4.0 -write-delegation disabled
Disable NFSv4.1 write file delegations	Enter the following command: vserver nfs modify -vserver vserver_name -v4.1 -write-delegation disabled

Result

The file delegation options take effect as soon as they are changed. There is no need to reboot or restart NFS.

Configure NFSv4 file and record locking

About NFSv4 file and record locking

For NFSv4 clients, ONTAP supports the NFSv4 file-locking mechanism, maintaining the state of all file locks under a lease-based model.

[NetApp Technical Report 3580: NFSv4 Enhancements and Best Practices Guide Data ONTAP Implementation](#)

Specify the NFSv4 locking lease period

To specify the NFSv4 locking lease period (that is, the time period in which ONTAP irrevocably grants a lock to a client), you can modify the `-v4-lease-seconds` option. Shorter lease periods speed up server recovery while longer lease periods are beneficial for servers handling a very large amount of clients.

About this task

By default, this option is set to 30. The minimum value for this option is 10. The maximum value for this option is the locking grace period, which you can set with the `locking.lease_seconds` option.

Steps

- Set the privilege level to advanced:

```
set -privilege advanced
```

- Enter the following command:

```
vserver nfs modify -vserver vserver_name -v4-lease-seconds number_of_seconds
```

- Return to the admin privilege level:

```
set -privilege admin
```

Specify the NFSv4 locking grace period

To specify the NFSv4 locking grace period (that is, the time period in which clients attempt to reclaim their locking state from ONTAP during server recovery), you can modify the `-v4-grace-seconds` option.

About this task

By default, this option is set to 45.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Enter the following command:

```
vserver nfs modify -vserver vserver_name -v4-grace-seconds number_of_seconds
```

3. Return to the admin privilege level:

```
set -privilege admin
```

How NFSv4 referrals work

When you enable NFSv4 referrals, ONTAP provides “intra-SVM” referrals to NFSv4 clients. Intra-SVM referral is when a cluster node receiving the NFSv4 request refers the NFSv4 client to another logical interface (LIF) on the storage virtual machine (SVM).

The NFSv4 client should access the path that received the referral at the target LIF from that point onward. The original cluster node provides such a referral when it determines that there exists a LIF in the SVM that is resident on the cluster node on which the data volume resides, thereby enabling the clients faster access to the data and avoiding extra cluster communication.

Enable or disable NFSv4 referrals

You can enable NFSv4 referrals on storage virtual machines (SVMs) by enabling the options `-v4-fsid-change` and `-v4.0-referrals` or `-v4.1-referrals`. Enabling NFSv4 referrals can result in faster data access for NFSv4 clients that support this feature.

What you'll need

If you want to enable NFS referrals, you must first disable parallel NFS. You cannot enable both at the same time.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Perform one of the following actions:

If you want to...	Enter the command...
Enable NFSv4 referrals	vserver nfs modify -vserver vserver_name -v4-fsid -change enabled vserver nfs modify -vserver vserver_name -v4.0-referrals enabled
Disable NFSv4 referrals	vserver nfs modify -vserver vserver_name -v4.0 -referrals disabled
Enable NFSv4.1 referrals	vserver nfs modify -vserver vserver_name -v4-fsid -change enabled vserver nfs modify -vserver vserver_name -v4.1-referrals enabled
Disable NFSv4.1 referrals	vserver nfs modify -vserver vserver_name -v4.1 -referrals disabled

3. Return to the admin privilege level:

```
set -privilege admin
```

Display NFS statistics

You can display NFS statistics for storage virtual machines (SVMs) on the storage system to monitor performance and diagnose issues.

Steps

1. Use the `statistics catalog object show` command to identify the NFS objects from which you can view data.

```
statistics catalog object show -object nfs*
```

2. Use the `statistics start` and optional `statistics stop` commands to collect a data sample from one or more objects.

3. Use the `statistics show` command to view the sample data.

Example: Monitoring NFSv3 performance

The following example shows performance data for the NFSv3 protocol.

The following command starts data collection for a new sample:

```
vsl:::> statistics start -object nfsv3 -sample-id nfs_sample
```

The following command shows data from the sample by specifying counters that show the number of successful read and write requests versus the total number of read and write requests:

```
vs1::> statistics show -sample-id nfs_sample -counter  
read_total|write_total|read_success|write_success
```

Object: nfsv3

Instance: vs1

Start-time: 2/11/2013 15:38:29

End-time: 2/11/2013 15:38:41

Cluster: cluster1

Counter	Value
<hr/>	
read_success	40042
read_total	40042
write_success	1492052
write_total	1492052

Display DNS statistics

You can display DNS statistics for storage virtual machines (SVMs) on the storage system to monitor performance and diagnose issues.

Steps

1. Use the `statistics catalog object show` command to identify the DNS objects from which you can view data.

```
statistics catalog object show -object external_service_op*
```

2. Use the `statistics start` and `statistics stop` commands to collect a data sample from one or more objects.

3. Use the `statistics show` command to view the sample data.

Monitoring DNS statistics

The following examples show performance data for DNS queries. The following commands start data collection for a new sample:

```
vs1::*> statistics start -object external_service_op -sample-id  
dns_sample1  
vs1::*> statistics start -object external_service_op_error -sample-id  
dns_sample2
```

The following command displays data from the sample by specifying counters that display the number of DNS queries sent versus the number of DNS queries received, failed, or timed out:

```

vs1::*> statistics show -sample-id dns_sample1 -counter
num_requests_sent|num_responses_received|num_successful_responses|num_time
outs|num_request_failures|num_not_found_responses

Object: external_service_op
Instance: vs1:DNS:Query:10.72.219.109
Start-time: 3/8/2016 11:15:21
End-time: 3/8/2016 11:16:52
Elapsed-time: 91s
Scope: vs1

Counter                                Value
-----
num_not_found_responses                0
num_request_failures                  0
num_requests_sent                     1
num_responses_received                1
num_successful_responses              1
num_timeouts                          0
6 entries were displayed.

```

The following command displays data from the sample by specifying counters that display the number of times a specific error was received for a DNS query on the particular server:

```

vs1::*> statistics show -sample-id dns_sample2 -counter
server_ip_address|error_string|count

Object: external_service_op_error
Instance: vs1:DNS:Query:NXDOMAIN:10.72.219.109
Start-time: 3/8/2016 11:23:21
End-time: 3/8/2016 11:24:25
Elapsed-time: 64s
Scope: vs1

Counter                                Value
-----
count                                  1
error_string                           NXDOMAIN
server_ip_address                      10.72.219.109
3 entries were displayed.

```

Display NIS statistics

You can display NIS statistics for storage virtual machines (SVMs) on the storage system to monitor performance and diagnose issues.

Steps

1. Use the `statistics catalog object show` command to identify the NIS objects from which you can view data.

```
statistics catalog object show -object external_service_op*
```

2. Use the `statistics start` and `statistics stop` commands to collect a data sample from one or more objects.
3. Use the `statistics show` command to view the sample data.

Monitoring NIS statistics

The following examples display performance data for NIS queries. The following commands start data collection for a new sample:

```
vs1::*: > statistics start -object external_service_op -sample-id  
nis_sample1  
vs1::*: > statistics start -object external_service_op_error -sample-id  
nis_sample2
```

The following command displays data from the sample by specifying counters that show the number of NIS queries sent versus the number of NIS queries received, failed, or timed out:

```

vs1::*> statistics show -sample-id nis_sample1 -counter
instance|num_requests_sent|num_responses_received|num_successful_responses
|num_timeouts|num_request_failures|num_not_found_responses

Object: external_service_op
Instance: vs1:NIS:Query:10.227.13.221

Support for VMware vStorage over NFS

ONTAP supports certain VMware vStorage APIs for Array Integration (VAAI) features in an NFS environment.

Supported features

The following features are supported:

- Copy offload

Enables an ESXi host to copy virtual machines or virtual machine disks (VMDKs) directly between the source and destination data store location without involving the host. This conserves ESXi host CPU cycles and network bandwidth. Copy offload preserves space efficiency if the source volume is sparse.

- Space reservation

Guarantees storage space for a VMDK file by reserving space for it.

Limitations

VMware vStorage over NFS has the following limitations:

- Copy offload operations can fail in the following scenarios:
 - While running wafliron on the source or destination volume because it temporarily takes the volume offline
 - While moving either the source or destination volume
 - While moving either the source or destination LIF
 - While performing takeover or giveback operations
 - While performing switchover or switchback operations
- Server-side copy can fail due to file handle format differences in the following scenario:

You attempt to copy data from SVMs that have currently or had previously exported qtrees to SVMs that have never had exported qtrees. To work around this limitation, you can export at least one qtree on the destination SVM.

Related information

[What VAAI offloaded operations are supported by Data ONTAP?](#)

Enable or disable VMware vStorage over NFS

You can enable or disable support for VMware vStorage over NFS on storage virtual machines (SVMs) by using the `vserver nfs modify` command.

About this task

By default, support for VMware vStorage over NFS is disabled.

Steps

1. Display the current vStorage support status for SVMs:

```
vserver nfs show -vserver vserver_name -instance
```

2. Perform one of the following actions:

If you want to...	Enter the following command...
Enable VMware vStorage support	vserver nfs modify -vserver vserver_name -vstorage enabled
Disable VMware vStorage support	vserver nfs modify -vserver vserver_name -vstorage disabled

After you finish

You must install the NFS Plug-in for VMware VAAI before you can use this functionality. For more information, see *Installing the NetApp NFS Plug-in for VMware VAAI*.

Related information

[NetApp Documentation: NetApp NFS Plug-in for VMware VAAI](#)

Enable or disable rquota support

ONTAP supports the remote quota protocol version 1 (rquota v1). The rquota protocol enables NFS clients to obtain quota information for users from a remote machine. You can enable rquota on storage virtual machines (SVMs) by using the `vserver nfs modify` command.

About this task

By default, rquota is disabled.

Step

1. Perform one of the following actions:

If you want to...	Enter the following command...
Enable rquota support for SVMs	vserver nfs modify -vserver vserver_name -rquota enable
Disable rquota support for SVMs	vserver nfs modify -vserver vserver_name -rquota disable

For more information about quotas, see [Logical storage management](#).

NFSv3 and NFSv4 performance improvement by modifying the TCP transfer size

You can improve the performance of NFSv3 and NFSv4 clients connecting to storage systems over a high-latency network by modifying the TCP maximum transfer size.

When clients access storage systems over a high-latency network, such as a wide area network (WAN) or

metro area network (MAN) with a latency over 10 milliseconds, you might be able to improve the connection performance by modifying the TCP maximum transfer size. Clients accessing storage systems in a low-latency network, such as a local area network (LAN), can expect little to no benefit from modifying these parameters. If the throughput improvement does not outweigh the latency impact, you should not use these parameters.

To determine whether your storage environment would benefit from modifying these parameters, you should first conduct a comprehensive performance evaluation of a poorly performing NFS client. Review whether the low performance is because of excessive round trip latency and small request on the client. Under these conditions, the client and server cannot fully use the available bandwidth because they spend the majority of their duty cycles waiting for small requests and responses to be transmitted over the connection.

By increasing the NFSv3 and NFSv4 request size, the client and server can use the available bandwidth more effectively to move more data per unit time; therefore, increasing the overall efficiency of the connection.

Keep in mind that the configuration between the storage system and the client might vary. The storage system and the client supports maximum size of 1 MB for transfer operations. However, if you configure the storage system to support 1 MB maximum transfer size but the client only supports 64 KB, then the mount transfer size is limited to 64 KB or less.

Before modifying these parameters, you must be aware that it results in additional memory consumption on the storage system for the period of time necessary to assemble and transmit a large response. The more high-latency connections to the storage system, the higher the additional memory consumption. Storage systems with high memory capacity might experience very little effect from this change. Storage systems with low memory capacity might experience noticeable performance degradation.

The successful use of these parameter relies on the ability to retrieve data from multiple nodes of a cluster. The inherent latency of the cluster network might increase the overall latency of the response. Overall latency tends to increase when using these parameters. As a result, latency sensitive workloads might show negative impact.

Modify the NFSv3 and NFSv4 TCP maximum transfer size

You can modify the `-tcp-max-xfer-size` option to configure maximum transfer sizes for all TCP connections using the NFSv3 and NFSv4.x protocols.

About this task

You can modify these options individually for each storage virtual machine (SVM).

Beginning with ONTAP 9, the `v3-tcp-max-read-size` and `v3-tcp-max-write-size` options are obsolete. You must use the `-tcp-max-xfer-size` option instead.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Perform one of the following actions:

If you want to...	Enter the command...
Modify the NFSv3 or NFSv4 TCP maximum transfer size	<pre>vserver nfs modify -vserver vserver_name -tcp-max-xfer-size integer_max_xfer_size</pre>

Option	Range	Default
-tcp-max-xfer-size	8192 to 1048576 bytes	65536 bytes

The maximum transfer size that you enter must be a multiple of 4 KB (4096 bytes). Requests that are not properly aligned negatively affect performance.

3. Use the `vserver nfs show -fields tcp-max-xfer-size` command to verify the changes.
4. If any clients use static mounts, unmount and remount for the new parameter size to take effect.

Example

The following command sets the NFSv3 and NFSv4.x TCP maximum transfer size to 1048576 bytes on the SVM named vs1:

```
vs1::> vserver nfs modify -vserver vs1 -tcp-max-xfer-size 1048576
```

Configure the number of group IDs allowed for NFS users

By default, ONTAP supports up to 32 group IDs when handling NFS user credentials using Kerberos (RPCSEC_GSS) authentication. When using AUTH_SYS authentication, the default maximum number of group IDs is 16, as defined in RFC 5531. You can increase the maximum up to 1,024 if you have users who are members of more than the default number of groups.

About this task

If a user has more than the default number of group IDs in their credentials, the remaining group IDs are truncated and the user might receive errors when attempting to access files from the storage system. You should set the maximum number of groups, per SVM, to a number that represents the maximum groups in your environment.

The following table shows the two parameters of the `vserver nfs modify` command that determine the maximum number of group IDs in three sample configurations:

Parameters	Settings	Resulting group IDs limit
<code>-extended-groups-limit</code>	32	RPCSEC_GSS: 32
<code>-auth-sys-extended-groups</code>	disabled	AUTH_SYS: 16
		These are the default settings.
<code>-extended-groups-limit</code>	256	RPCSEC_GSS: 256
<code>-auth-sys-extended-groups</code>	disabled	AUTH_SYS: 16

-extended-groups-limit	512	RPCSEC_GSS: 512
-auth-sys-extended-groups	enabled	AUTH_SYS: 512

Some older NFS clients might not be compatible with AUTH_SYS extended groups.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Perform the desired action:

If you want to set the maximum number of allowed auxiliary groups...	Enter the command...
Only for RPCSEC_GSS and leave AUTH_SYS set to the default value of 16	vserver nfs modify -vserver vserver_name -extended-groups-limit {32-1024} -auth-sys-extended-groups disabled
For both RPCSEC_GSS and AUTH_SYS	vserver nfs modify -vserver vserver_name -extended-groups-limit {32-1024} -auth-sys-extended-groups enabled

3. Verify the -extended-groups-limit value and verify whether AUTH_SYS is using extended groups:

```
vserver nfs show -vserver vserver_name -fields auth-sys-extended-groups,extended-groups-limit
```

4. Return to the admin privilege level:

```
set -privilege admin
```

Example

The following example enables extended groups for AUTH_SYS authentication and sets the maximum number of extended groups to 512 for both AUTH_SYS and RPCSEC_GSS authentication. These changes are made only for clients who access the SVM named vs1:

```

vs1::> set -privilege advanced
Warning: These advanced commands are potentially dangerous; use
        them only when directed to do so by NetApp personnel.
Do you want to continue? {y|n}: y

vs1::*> vserver nfs modify -vserver vs1 -auth-sys-extended-groups enabled
-extended-groups-limit 512

vs1::*> vserver nfs show -vserver vs1 -fields auth-sys-extended-
groups,extended-groups-limit
vserver auth-sys-extended-groups extended-groups-limit
-----
vs1      enabled          512

vs1::*> set -privilege admin

```

Control root user access to NTFS security-style data

You can configure ONTAP to allow NFS clients access to NTFS security-style data and NTFS clients to access NFS security-style data. When using NTFS security style on an NFS data store, you must decide how to treat access by the root user and configure the storage virtual machine (SVM) accordingly.

About this task

When a root user accesses NTFS security-style data, you have two options:

- Map the root user to a Windows user like any other NFS user and manage access according to NTFS ACLs.
- Ignore NTFS ACLs and provide full access to root.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Perform the desired action:

If you want the root user to...	Enter the command...
Be mapped to a Windows user	vserver nfs modify -vserver vserver_name -ignore -nt-acl-for-root disabled
Bypass the NT ACL check	vserver nfs modify -vserver vserver_name -ignore -nt-acl-for-root enabled

By default, this parameter is disabled.

If this parameter is enabled but there is no name mapping for the root user, ONTAP uses a default SMB administrator credential for auditing.

3. Return to the admin privilege level:

```
set -privilege admin
```

Appendix: Supported NFS versions and clients

Appendix: Supported NFS versions and clients

Before you can use NFS in your network, you need to know which NFS versions and clients ONTAP supports.

ONTAP supports the following major and minor NFS protocol versions:

Version	Enabled by default
NFSv3	Yes
NFSv4.0	Yes, beginning with ONTAP 9.9.1
NFSv4.1	Yes, beginning with ONTAP 9.9.1
NFSv4.2	Yes, beginning with ONTAP 9.9.1
pNFS	No

For the latest information about which NFS clients ONTAP supports, see the Interoperability Matrix.

[NetApp Interoperability Matrix Tool](#)

NFSv4.0 functionality supported by ONTAP

ONTAP supports all the mandatory functionality in NFSv4.0 except the SPKM3 and LIPKEY security mechanisms.

The following NFSV4 functionality is supported:

- **COMPOUND**

Allows a client to request multiple file operations in a single remote procedure call (RPC) request.

- **File delegation**

Allows the server to delegate file control to some types of clients for read and write access.

- **Pseudo-fs**

Used by NFSv4 servers to determine mount points on the storage system. There is no mount protocol in NFSv4.

- **Locking**

Lease-based. There are no separate Network Lock Manager (NLM) or Network Status Monitor (NSM) protocols in NFSv4.

For more information about the NFSv4.0 protocol, see RFC 3530.

Limitations of ONTAP support for NFSv4

You should be aware of several limitations of ONTAP support for NFSv4.

- The delegation feature is not supported by every client type.
- In ONTAP 9.4 and earlier releases, names with non-ASCII characters on volumes other than UTF8 volumes are rejected by the storage system.

In ONTAP 9.5 and later releases, volumes created with the utf8mb4 language setting and mounted using NFS v4 are no longer subject to this restriction.

- All file handles are persistent; the server does not give volatile file handles.
- Migration and replication are not supported.
- NFSv4 clients are not supported with read-only load-sharing mirrors.

ONTAP routes NFSv4 clients to the source of the load-sharing mirror for direct read and write access.

- Named attributes are not supported.
- All recommended attributes are supported, except for the following:

- archive
- hidden
- homogeneous
- mimetype
- quota_avail_hard
- quota_avail_soft
- quota_used
- system
- time_backup

Although it does not support the quota* attributes, ONTAP does support user and group quotas through the RQUOTA side band protocol.

ONTAP support for NFSv4.1

Beginning with ONTAP 9.8, nconnect functionality is available by default when NFSv4.1 is enabled.

Earlier NFS client implementations use only a single TCP connection with a mount. In ONTAP, a single TCP

connection can become a bottleneck with increasing IOPS. However, an nconnect-enabled client can have multiple TCP connections (up to 16) associated with a single NFS mount. Such an NFS client multiplexes file operations onto multiple TCP connections in a round-robin fashion and thus obtains higher throughput from the available network bandwidth. Nconnect is recommended for NFSv3 and NFSv4.1 mounts only.

See your NFS client documentation to confirm whether nconnect is supported in your client version.

NFSv4.1 is enabled by default in ONTAP 9.9.1 and later. In earlier releases, you can enable it by specifying the `-v4.1` option and setting it to `enabled` when creating an NFS server on the storage virtual machine (SVM).

ONTAP does not support NFSv4.1 directory and file level delegations.

ONTAP support for NFSv4.2

Beginning with ONTAP 9.8, the NFSv4.2 protocol is supported to allow access for NFSv4.2 clients.

NFSv4.2 is enabled by default in ONTAP 9.9.1 and later. In ONTAP 9.8, you can enable v4.2 by specifying the `-v4.1` option and setting it to `enabled` when creating an NFS server on the storage virtual machine (SVM). Enabling NFSv4.1 also enables clients to use the NFSv4.1 features while mounted as v4.2.

The following NFSv4.2 optional features are supported:

- Beginning with ONTAP 9.9.1, Mandatory Access Control (MAC) labelled NFS is supported when NFSv4.2 is enabled.
- Additional NFSv4.2 optional features will be added in a later ONTAP release.

Enable NFS v4.2 security labels

Beginning with ONTAP 9.9.1, NFS security labels can be enabled. They are disabled by default.

With NFS v4.2 security labels, ONTAP NFS servers are Mandatory Access Control (MAC) aware, storing and retrieving `sec_label` attributes sent by clients.

For more information, see [RFC7240](#)

NFS v4.2 security labels are not currently supported for NDMP dump operations. If security labels are encountered on files or directories, the dump fails.

Steps

1. Change the privilege setting to advanced:

```
set -privilege advanced
```

2. Enable security labels:

```
vserver nfs modify -vserver svm_name -v4.2-seclabel enabled
```

ONTAP support for parallel NFS

ONTAP supports parallel NFS (pNFS). The pNFS protocol offers performance improvements by giving clients direct access to the data of a set of files distributed across

multiple nodes of a cluster. It helps clients locate the optimal path to a volume.

Use of hard mounts

When troubleshooting mounting problems, you need to be sure that you are using the correct mount type. NFS supports two mount types: soft mounts and hard mounts. You should use only hard mounts for reliability reasons.

You should not use soft mounts, especially when there is a possibility of frequent NFS timeouts. Race conditions can occur as a result of these timeouts, which can lead to data corruption.

Appendix: NFS and SMB file and directory naming dependencies

Appendix: NFS and SMB file and directory naming dependencies

File and directory naming conventions depend on both the network clients' operating systems and the file-sharing protocols, in addition to language settings on the ONTAP cluster and clients.

The operating system and the file-sharing protocols determine the following:

- Characters a file name can use
- Case-sensitivity of a file name

ONTAP supports multi-byte characters in file, directory, and qtree names, depending on the ONTAP release.

Characters a file or directory name can use

If you are accessing a file or directory from clients with different operating systems, you should use characters that are valid in both operating systems.

For example, if you use UNIX to create a file or directory, do not use a colon (:) in the name because the colon is not allowed in MS-DOS file or directory names. Because restrictions on valid characters vary from one operating system to another, see the documentation for your client operating system for more information about prohibited characters.

Case-sensitivity of file and directory names in a multiprotocol environment

File and directory names are case-sensitive for NFS clients and case-insensitive but case-preserving for SMB clients. You must understand what the implications are in a multiprotocol environment and the actions you might need to take when specifying the path while creating SMB shares and when accessing data within the shares.

If an SMB client creates a directory named testdir, both SMB and NFS clients display the file name as testdir. However, if an SMB user later tries to create a directory name TESTDIR, the name is not allowed because, to the SMB client, that name currently exists. If an NFS user later creates a directory named TESTDIR, NFS and SMB clients display the directory name differently, as follows:

- On NFS clients, you see both directory names as they were created, for example testdir and TESTDIR, because directory names are case-sensitive.

- SMB clients use the 8.3 names to distinguish between the two directories. One directory has the base file name. Additional directories are assigned an 8.3 file name.

- On SMB clients, you see `testdir` and `TESTDI~1`.
- ONTAP creates the `TESTDI~1` directory name to differentiate the two directories.

In this case, you must use the 8.3 name when specifying a share path while creating or modifying a share on a storage virtual machine (SVM).

Similarly for files, if an SMB client creates `test.txt`, both SMB and NFS clients display the file name as `text.txt`. However, if an SMB user later tries to create `Test.txt`, the name is not allowed because, to the SMB client, that name currently exists. If an NFS user later creates a file named `Test.txt`, NFS and SMB clients display the file name differently, as follows:

- On NFS clients, you see both file names as they were created, `test.txt` and `Test.txt`, because file names are case-sensitive.
- SMB clients use the 8.3 names to distinguish between the two files. One file has the base file name. Additional files are assigned an 8.3 file name.
 - On SMB clients, you see `test.txt` and `TEST~1.TXT`.
 - ONTAP creates the `TEST~1.TXT` file name to differentiate the two files.

If you have enabled or modified character mapping using the Vserver CIFS character-mapping commands, a normally case-insensitive Windows lookup becomes case-sensitive.

How ONTAP creates file and directory names

ONTAP creates and maintains two names for files or directories in any directory that has access from an SMB client: the original long name and a name in 8.3 format.

For file or directory names that exceed the eight character name or the three character extension limit (for files), ONTAP generates an 8.3-format name as follows:

- It truncates the original file or directory name to six characters, if the name exceeds six characters.
- It appends a tilde (~) and a number, one through five, to file or directory names that are no longer unique after being truncated.

If it runs out of numbers because there are more than five similar names, it creates a unique name that bears no relation to the original name.

- In the case of files, it truncates the file name extension to three characters.

For example, if an NFS client creates a file named `specifications.html`, the 8.3 format file name created by ONTAP is `specif~1.htm`. If this name already exists, ONTAP uses a different number at the end of the file name. For example, if an NFS client then creates another file named `specifications_new.html`, the 8.3 format of `specifications_new.html` is `specif~2.htm`.

How ONTAP handles multi-byte file, directory, and qtree names

Beginning with ONTAP 9.5, support for 4-byte UTF-8 encoded names enables the creation and display of file, directory, and tree names that include Unicode supplementary

characters outside the Basic Multilingual Plane (BMP). In earlier releases, these supplementary characters did not display correctly in multiprotocol environments.

To enable support for 4-byte UTF-8 encoded names, a new *utf8mb4* language code is available for the `vserver` and `volume` command families.

- You must create a new volume in one of the following ways:
- Setting the `volume -language` option explicitly:

```
volume create -language utf8mb4 {...}
```

- Inheriting the `volume -language` option from an SVM that has been created with or modified for the option:

```
vserver [create|modify] -language utf8mb4 {...}``volume create {...}
```

- You cannot modify existing volumes for `utf8mb4` support; you must create a new `utf8mb4`-ready volume, and then migrate the data using client-based copy tools.

You can update SVMs for `utf8mb4` support, but existing volumes retain their original language codes.

LUN names with 4-byte UTF-8 characters are not currently supported.

- Unicode character data is typically represented in Windows file systems applications using the 16-bit Unicode Transformation Format (UTF-16) and in NFS file systems using the 8-bit Unicode Transformation Format (UTF-8).

In releases prior to ONTAP 9.5, names including UTF-16 supplementary characters that were created by Windows clients were correctly displayed to other Windows clients but were not translated correctly to UTF-8 for NFS clients. Similarly, names with UTF-8 supplementary characters by created NFS clients were not translated correctly to UTF-16 for Windows clients.

- When you create file names on systems running ONTAP 9.4 or earlier that contain valid or invalid supplementary characters, ONTAP rejects the file name and returns an invalid file name error.

To avoid this issue, use only BMP characters in file names and avoid using supplementary characters, or upgrade to ONTAP 9.5 or later.

Unicode characters are allowed in qtree names.

- You can use either the `volume qtree` command family or System Manager to set or modify qtree names.
- qtree names can include multi-byte characters in Unicode format, such as Japanese and Chinese characters.
- In releases before ONTAP 9.5, only BMP characters (that is, those that could be represented in 3 bytes) were supported.

In releases before ONTAP 9.5, the junction-path of the qtree's parent volume can contain qtree and directory names with Unicode characters. The `volume show` command displays these names correctly when the parent volume has a UTF-8 language setting. However, if the parent volume language is not one of the UTF-8 language settings, some parts of the junction-path are displayed using a numeric NFS alternate name.

- In 9.5 and later releases, 4-byte characters are supported in qtree names, provided that the qtree is in a volume enabled for utf8mb4.

Configure character mapping for SMB file name translation on volumes

NFS clients can create file names that contain characters that are not valid for SMB clients and certain Windows applications. You can configure character mapping for file name translation on volumes to allow SMB clients to access files with NFS names that would otherwise not be valid.

About this task

When files created by NFS clients are accessed by SMB clients, ONTAP looks at the name of the file. If the name is not a valid SMB file name (for example, if it has an embedded colon ":" character), ONTAP returns the 8.3 file name that is maintained for each file. However, this causes problems for applications that encode important information into long file names.

Therefore, if you are sharing a file between clients on different operating systems, you should use characters in the file names that are valid in both operating systems.

However, if you have NFS clients that create file names containing characters that are not valid file names for SMB clients, you can define a map that converts the invalid NFS characters into Unicode characters that both SMB and certain Windows applications accept. For example, this functionality supports the CATIA MCAD and Mathematica applications as well as other applications that have this requirement.

You can configure character mapping on a volume-by-volume basis.

You must keep the following in mind when configuring character mapping on a volume:

- Character mapping is not applied across junction points.

You must explicitly configure character mapping for each junction volume.

- You must make sure that the Unicode characters that are used to represent invalid or illegal characters are characters that do not normally appear in file names; otherwise, unwanted mappings occur.

For example, if you try to map a colon (:) to a hyphen (-) but the hyphen (-) was used in the file name correctly, a Windows client trying to access a file named "a-b" would have its request mapped to the NFS name of "a:b" (not the desired outcome).

- After applying character mapping, if the mapping still contains an invalid Windows character, ONTAP falls back to Windows 8.3 file names.
- In FPolicy notifications, NAS audit logs, and security trace messages, the mapped file names are shown.
- When a SnapMirror relation of type DP is created, the source volume's character mapping is not replicated on the destination DP volume.
- Case sensitivity: Because the mapped Windows names turn into NFS names, the lookup of the names follows NFS semantics. That includes the fact that NFS lookups are case-sensitive. This means that the applications accessing mapped shares must not rely on Windows case-insensitive behavior. However, the 8.3 name is available, and that is case-insensitive.
- Partial or invalid mappings: After mapping a name to return to clients doing directory enumeration ("dir"), the resulting Unicode name is checked for Windows validity. If that name still has invalid characters in it, or if it is otherwise invalid for Windows (e.g. it ends in "." or blank) the 8.3 name is returned instead of the invalid name.

Step

1. Configure character mapping:

```
vserver cifs character-mapping create -vserver vserver_name -volume  
volume_name -mapping mapping_text, ...
```

The mapping consists of a list of source-target character pairs separated by ":". The characters are Unicode characters entered using hexadecimal digits. For example: 3C:E03C.

The first value of each `mapping_text` pair that is separated by a colon is the hexadecimal value of the NFS character you want to translate, and the second value is the Unicode value that SMB uses. The mapping pairs must be unique (a one-to-one mapping should exist).

- Source mapping

The following table shows the permissible Unicode character set for source mapping:

Unicode character	Printed character	Description
0x01-0x19	Not applicable	Non-printing control characters
0x5C	\	Backslash
0x3A	:	Colon
0x2A	*	Asterisk
0x3F	?	Question mark
0x22	"	Quotation mark
0x3C	<	Less than
0x3E	>	Greater than
0x7C		Vertical line
0xB1	±	Plus-minus sign

- Target mapping

You can specify target characters in the “Private Use Area” of Unicode in the following range: U+E0000...U+F8FF.

Example

The following command creates a character mapping for a volume named “data” on storage virtual machine (SVM) vs1:

```

cluster1::> vserver cifs character-mapping create -volume data -mapping
3c:e17c,3e:f17d,2a:f745
cluster1::> vserver cifs character-mapping show

Vserver          Volume Name   Character Mapping
-----
vs1              data          3c:e17c, 3e:f17d, 2a:f745

```

Commands for managing character mappings for SMB file name translation

You can manage character mapping by creating, modifying, displaying information about, or deleting file character mappings used for SMB file name translation on FlexVol volumes.

If you want to...	Use this command...
Create new file character mappings	vserver cifs character-mapping create
Display information about file character mappings	vserver cifs character-mapping show
Modify existing file character mappings	vserver cifs character-mapping modify
Delete file character mappings	vserver cifs character-mapping delete

For more information, see the man page for each command.

Manage NFS over RDMA

NFS over RDMA

NFS over RDMA utilizes RDMA adapters, allowing data to be copied directly between storage system memory and host system memory, circumventing CPU interruptions and overhead.

NFS over RDMA configurations are designed for customers with latency sensitive or high-bandwidth workloads such as machine learning and analytics. NVIDIA has extended NFS over RDMA to enable GPU Direct Storage (GDS). GDS further accelerates GPU-enabled workloads by bypassing the CPU and main memory altogether using RDMA to transfer data between the storage system and GPU memory directly.

In ONTAP 9.10.1, this configuration is only supported for the NFSv4.0 protocol when used with the Mellanox CX-5 or CX-6 adapter, which provides support for RDMA using version 2 of the RoCE protocol. GDS is only supported using NVIDIA Tesla- and Ampere-family GPUs with Mellanox NIC cards and MOFED software. NFS over RDMA support is limited to node-local traffic only. Standard FlexVols or FlexGroups where all constituents are on the same node are supported and must be accessed from a LIF on the same node. NFS mount sizes higher than 64k result in unstable performance with NFS over RDMA configurations.

Requirements

- Storage systems must be running ONTAP 9.10.1
- Both nodes in the HA pair must be the same version
- Storage system controllers must have RDMA support (currently A400, A700, and A800)
- Storage appliance configured with RDMA-supported hardware (e.g. Mellanox CX-5 or CX-6)
- Data LIFs must be configured to support RDMA.
- Clients must be using Mellanox RDMA-capable NIC cards and Mellanox OFED (MOFED) network software.

Next Steps

- [Configure NICs for NFS over RDMA](#)
- [Configure LIFs for NFS over RDMA](#)
- [NFS settings for NFS over RDMA](#)

Further reading

- [RFC 7530: NFS Version 4 Protocol](#)
- [RFC 8166: Remote Direct Memory Access Transport for Remote Procedure Call Version 1](#)
- [RFC 8167: Bidirectional Remote Procedure Call on RPC-over-RDMA Transports](#)
- [RFC 8267: NFS Upper-Layer Binding to RPC-over-RDMA version 1](#)

Configure NICs for NFS over RDMA

NFS over RDMA requires NIC configuration for both the client system and storage platform.

Storage platform configuration

An X1148 RDMA adapter needs to be installed on the server. If you are using an HA configuration, you must have a corresponding X1148 adapter on the failover partner so RDMA service can continue during failover. The NIC must be ROCE capable.

Beginning with ONTAP 9.10.1, you can view a list of RDMA offload protocols with the command:

```
network port show -rdma-protocols roce
```

Client system configuration

Clients must be using Mellanox RDMA-capable NIC cards (e.g. X1148) and Mellanox OFED network software. Consult Mellanox documentation for supported models and versions. Although the client and server can be directly connected, the use of switches is recommended due to improved failover performance with a switch.

The client, server, and any switches, and all ports on switches must be configured using Jumbo frames. Also ensure that priority flow-control is in effect on any switches.

Once this configuration is confirmed, you can mount the NFS.

Steps

1. Check if RDMA access is enabled on the NFS server with the command:

```
vserver nfs show-vserver vserver_name
```

By default, `-rdma` should be enabled. If it is not, enable RDMA access on the NFS server:

```
vserver nfs modify -vserver vserver_name -rdma enabled
```

2. Mount the client via NFSv4.0 over RDMA:

- The input for the `proto` parameter depends on the server IP protocol version. If it is v4, use `proto=rdma`. If it is v6, use `proto=rdma6`.
- Specify the NFS target port as `port=20049` instead of the standard port of 2049:

```
mount -o vers=4,minorversion=0,proto=rdma,port=20049 Server_IP_address  
:/volume_path mount_point
```

3. OPTIONAL: If you need to unmount the client, run the command `umount mount_path`

Configure LIFs for NFS over RDMA

To utilize NFS over RDMA, you must configure your LIFs to be RDMA compatible. Both the LIF and its failover pair must be RDMA capable.

Beginning with ONTAP 9.10.1, there is a new `rdma_protocols` parameter on the network interface commands where you can configure support, along with setting an appropriate service policy.

Procedure to create a new LIF

1. Create a LIF:

```
network interface create -vserver vserver_name -lif lif_name -service-policy  
service_policy_name -home-node node_name -home-port port_name {-address  
IP_address -netmask netmask_value | -subnet-name subnet_name} -firewall-policy  
policy_name -auto-revert {true|false} -rdma-protocols roce
```

- The service policy must be either `default-data-files` or a custom policy that includes the `data-nfs` network interface service.
- The `-rdma-protocols` parameter accepts a list, which is by default empty. When `roce` is added as a value, the LIF can only be configured on ports supporting RoCE offload, affecting both LIF migration and failover.

Procedure to modify a LIF

1. You can check the status of your LIFs with the `network interface show` command. The service policy must include the `data-nfs` network interface service. The `-rdma-protocols` list should include `roce`. If either of these conditions are untrue, modify the LIF.

2. To modify the LIF, run:

```
network interface modify vserver vserver_name -lif lif_name -service-policy  
service_policy_name -home-node node_name -home-port port_name {-address  
IP_address -netmask netmask_value | -subnet-name subnet_name} -firewall-policy  
policy_name -auto-revert {true|false} -rdma-protocols roce
```

Modifying a LIF to require a particular offload protocol when the LIF is not currently assigned to a port that

supports that protocol will produce an error.

[Create a LIF](#)

[What LIFs are](#)

Modify the NFS configuration

In most cases, you will not need to modify the configuration of the NFS-enabled vserver for NFS over RDMA.

If you are, however, dealing with issues related to Mellanox chips and LIF migration, you should increase the NFSv4 locking grace period. By default, the grace period is set to 45 seconds. Beginning with ONTAP 9.10.1, the grace period can go as high as 180 seconds.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Enter the following command:

```
vserver nfs modify -vserver vserver_name -v4-grace-seconds number_of_seconds
```

For more about this task, see [Specifying the NFSv4 locking grace period](#).

Configure SMB with the CLI

SMB configuration overview with the CLI

You can use ONTAP 9 CLI commands to configure SMB client access to files contained in a new volume or qtree in a new or existing SVM.

SMB (Server Message Block) refers to modern dialects of the Common Internet File System (CIFS) protocol. You will still see CIFS in the ONTAP command-line interface (CLI) and in OnCommand management tools.

Use these procedures if you want to configure SMB access to a volume or qtree in the following way:

- You want to use SMB version 2 or later.
- You want to serve SMB clients only, not NFS clients (not a multiprotocol configuration).
- NTFS file permissions will be used to secure the new volume.
- You have cluster administrator privileges, not SVM administrator privileges.

Cluster administrator privileges are required to create SVMs and LIFs. SVM administrator privileges are sufficient for other SMB configuration tasks.

- You want to use the CLI, not System Manager or an automated scripting tool.

To use System Manager to configure NAS multiprotocol access, see [Provision NAS storage for both Windows and Linux using both NFS and SMB](#).

- You want to use best practices, not explore every available option.

Details about command syntax are available from CLI help and ONTAP man pages.

If you want details about the range of ONTAP SMB protocol capabilities, consult the [SMB reference overview](#).

Other ways to do this in ONTAP

To perform these tasks with...	Refer to...
The redesigned System Manager (available with ONTAP 9.7 and later)	Provision NAS storage for Windows servers using SMB
System Manager Classic (available with ONTAP 9.7 and earlier)	SMB configuration overview

SMB configuration workflow

Configuring SMB involves assessing physical storage and networking requirements, and then choosing a workflow that is specific to your goal; configuring SMB access to a new or existing SVM, or adding a volume or qtree to an existing SVM that is already fully configured for SMB access.

Preparation

Assess physical storage requirements

Before provisioning SMB storage for clients, you must ensure that there is sufficient space in an existing aggregate for the new volume. If there is not, you can add disks to an existing aggregate or create a new aggregate of the desired type.

Steps

1. Display available space in existing aggregates: `storage aggregate show`

If there is an aggregate with sufficient space, record its name in the worksheet.

```

cluster::> storage aggregate show
Aggregate      Size Available Used% State    #Vols  Nodes  RAID Status
-----  -----  -----  -----  -----  -----  -----  -----  -----
aggr_0        239.0GB  11.13GB  95% online     1 node1  raid_dp,
                                         normal
aggr_1        239.0GB  11.13GB  95% online     1 node1  raid_dp,
                                         normal
aggr_2        239.0GB  11.13GB  95% online     1 node2  raid_dp,
                                         normal
aggr_3        239.0GB  11.13GB  95% online     1 node2  raid_dp,
                                         normal
aggr_4        239.0GB  238.9GB  95% online     5 node3  raid_dp,
                                         normal
aggr_5        239.0GB  239.0GB  95% online     4 node4  raid_dp,
                                         normal
                                         6 entries were displayed.

```

2. If there are no aggregates with sufficient space, add disks to an existing aggregate by using the `storage aggregate add-disks` command, or create a new aggregate by using the `storage aggregate create` command.

Assess networking requirements

Before providing SMB storage to clients, you must verify that networking is correctly configured to meet the SMB provisioning requirements.

Before you begin

The following cluster networking objects must be configured:

- Physical and logical ports
- Broadcast domains
- Subnets (if required)
- IPspaces (as required, in addition to the default IPspace)
- Failover groups (as required, in addition to the default failover group for each broadcast domain)
- External firewalls

Steps

1. Display the available physical and virtual ports: `network port show`
 - When possible, you should use the port with the highest speed for the data network.
 - All components in the data network must have the same MTU setting for best performance.
2. If you are planning to use a subnet name to allocate the IP address and network mask value for a LIF, verify that the subnet exists and has sufficient addresses available: `network subnet show`

Subnets contain a pool of IP addresses that belong to the same layer 3 subnet. Subnets are created by using the `network subnet create` command.

3. Display available IPspaces: `network ipspace show`

You can use the default IPspace or a custom IPspace.

4. If you want to use IPv6 addresses, verify that IPv6 is enabled on the cluster: `network options ipv6 show`

If required, you can enable IPv6 by using the `network options ipv6 modify` command.

Decide where to provision new SMB storage capacity

Before you create a new SMB volume or qtree, you must decide whether to place it in a new or existing SVM, and how much configuration the SVM requires. This decision determines your workflow.

Choices

- If you want to provision a volume or qtree on a new SVM, or on an existing SVM that has SMB enabled but not configured, complete the steps in both “Configuring SMB access to an SVM” and “Adding storage capacity to an SMB-enabled SVM”.

[Configuring SMB access to an SVM](#)

[Configuring SMB client access to shared storage](#)

You might choose to create a new SVM if one of the following is true:

- You are enabling SMB on a cluster for the first time.
- You have existing SVMs in a cluster in which you do not want to enable SMB support.
- You have one or more SMB-enabled SVMs in a cluster, and you want one of the following connections:
 - To a different Active Directory forest or workgroup.
 - To an SMB server in an isolated namespace (multi-tenancy scenario).You should also choose this option to provision storage on an existing SVM that has SMB enabled but not configured. This might be the case if you created the SVM for SAN access or if no protocols were enabled when the SVM was created.

After enabling SMB on the SVM, proceed to provision a volume or qtree.

- If you want to provision a volume or qtree on an existing SVM that is fully configured for SMB access, complete the steps in “Adding storage capacity to an SMB-enabled SVM”.

[Configuring SMB client access to shared storage](#)

Worksheet for gathering SMB configuration information

The SMB configuration worksheet enables you to collect the required information to set up SMB access for clients.

You should complete one or both sections of the worksheet, depending on the decision you made about where to provision storage:

- If you are configuring SMB access to an SVM, you should complete both sections.

[Configuring SMB access to an SVM](#)

[Configuring SMB client access to shared storage](#)

- If you are adding storage capacity to an SMB-enabled SVM, you should complete only the second section.

[Configuring SMB client access to shared storage](#)

The command man pages contain details about the parameters.

Configuring SMB access to an SVM

Parameters for creating an SVM

You supply these values with the `vserver create` command if you are creating a new SVM.

Field	Description	Your value
<code>-vserver</code>	A name you supply for the new SVM that is either a fully qualified domain name (FQDN) or follows another convention that enforces unique SVM names across a cluster.	
<code>-aggregate</code>	The name of an aggregate in the cluster with sufficient space for new SMB storage capacity.	
<code>-rootvolume</code>	A unique name you supply for the SVM root volume.	
<code>-rootvolume-security-style</code>	Use the NTFS security style for the SVM.	ntfs
<code>-language</code>	Use the default language setting in this workflow.	C.UTF-8
<code>ipspace</code>	Optional: IPspaces are distinct IP address spaces in which SVMs reside.	

Parameters for creating a LIF

You supply these values with the `network interface create` command when you are creating LIFs.

Field	Description	Your value
<code>-lif</code>	A name you supply for the new LIF.	

Field	Description	Your value
-role	Use the data LIF role in this workflow.	data
-data-protocol	Use only the SMB protocol in this workflow.	cifs
-home-node	The node to which the LIF returns when the network interface revert command is run on the LIF.	
-home-port	The port or interface group to which the LIF returns when the network interface revert command is run on the LIF.	
-address	The IPv4 or IPv6 address on the cluster that will be used for data access by the new LIF.	
-netmask	The network mask and gateway for the LIF.	
-subnet	A pool of IP addresses. Used instead of -address and -netmask to assign addresses and netmasks automatically.	
-firewall-policy	Use the default data firewall policy in this workflow.	data
-auto-revert	Optional: Specifies whether a data LIF is automatically reverted to its home node on startup or under other circumstances. The default setting is false.	

Parameters for DNS host name resolution

You supply these values with the vserver services name-service dns create command when you are configuring DNS.

Field	Description	Your value
-domains	Up to five DNS domain names.	

Field	Description	Your value
-name-servers	Up to three IP addresses for each DNS name server.	

Setting up an SMB server in an Active Directory domain

Parameters for time service configuration

You supply these values with the `cluster time-service ntp server create` command when you are configuring time services.

Field	Description	Your value
-server	The host name or IP address of the NTP server for the Active Directory domain.	

Parameters for creating an SMB server in an Active Directory domain

You supply these values with the `vserver cifs create` command when you create a new SMB server and specify domain information.

Field	Description	Your value
-vserver	The name of the SVM on which to create the SMB server.	
-cifs-server	The name of the SMB server (up to 15 characters).	
-domain	The fully qualified domain name (FQDN) of the Active Directory domain to associate with the SMB server.	
-ou	Optional: The organizational unit within the Active Directory domain to associate with the SMB server. By default, this parameter is set to CN=Computers.	
-netbios-aliases	Optional: A list of NetBIOS aliases, which are alternate names to the SMB server name.	
-comment	Optional: A text comment for the server. Windows clients can see this SMB server description when browsing servers on the network.	

Setting up an SMB server in a workgroup

Parameters for creating an SMB server in a workgroup

You supply these values with the `vserver cifs create` command when you create a new SMB server and specify supported SMB versions.

Field	Description	Your value
<code>-vserver</code>	The name of the SVM on which to create the SMB server.	
<code>-cifs-server</code>	The name of the SMB server (up to 15 characters).	
<code>-workgroup</code>	The name of the workgroup (up to 15 characters).	
<code>-comment</code>	Optional: A text comment for the server. Windows clients can see this SMB server description when browsing servers on the network.	

Parameters for creating local users

You supply these values when you create local users by using the `vserver cifs users-and-groups local-user create` command. They are required for SMB servers in workgroups and optional in AD domains.

Field	Description	Your value
<code>-vserver</code>	The name of the SVM on which to create the local user.	
<code>-user-name</code>	The name of the local user (up to 20 characters).	
<code>-full-name</code>	Optional: The user's full name. If the full name contains a space, enclose the full name within double quotation marks.	
<code>-description</code>	Optional: A description for the local user. If the description contains a space, enclose the parameter in quotation marks.	

Field	Description	Your value
-is-account-disabled	Optional: Specifies whether the user account is enabled or disabled. If this parameter is not specified, the default is to enable the user account.	

Parameters for creating local groups

You supply these values when you create local groups by using the `vserver cifs users-and-groups local-group create` command. They are optional for SMB servers in AD domains and workgroups.

Field	Description	Your value
-vserver	The name of the SVM on which to create the local group.	
-group-name	The name of the local group (up to 256 characters).	
-description	Optional: A description for the local group. If the description contains a space, enclose the parameter in quotation marks.	

Adding storage capacity to an SMB-enabled SVM

Parameters for creating a volume

You supply these values with the `volume create` command if you are creating a volume instead of a qtree.

Field	Description	Your value
-vserver	The name of a new or existing SVM that will host the new volume.	
-volume	A unique descriptive name you supply for the new volume.	
-aggregate	The name of an aggregate in the cluster with sufficient space for the new SMB volume.	
-size	An integer you supply for the size of the new volume.	
-security-style	Use the NTFS security style for this workflow.	ntfs

Field	Description	Your value
-junction-path	Location under root (/) where the new volume is to be mounted.	

Parameters for creating a qtree

You supply these values with the `volume qtree create` command if you are creating a qtree instead of a volume.

Field	Description	Your value
-vserver	The name of the SVM on which the volume containing the qtree resides.	
-volume	The name of the volume that will contain the new qtree.	
-qtree	A unique descriptive name you supply for the new qtree, 64 characters or less.	
-qtree-path	The qtree path argument in the format <code>/vol/volume_name/qtree_name</code> can be specified instead of specifying volume and qtree as separate arguments.	

Parameters for creating SMB shares

You supply these values with the `vserver cifs share create` command.

Field	Description	Your value
-vserver	The name of the SVM on which to create the SMB share.	
-share-name	The name of the SMB share that you want to create (up to 256 characters).	
-path	The name of the path to the SMB share (up to 256 characters). This path must exist in a volume before creating the share.	

Field	Description	Your value
-share-properties	Optional: A list of share properties. The default settings are oplocks, browsable, changenotify, and show-previous-versions.	
-comment	Optional: A text comment for the server (up to 256 characters). Windows clients can see this SMB share description when browsing on the network.	

Parameters for creating SMB share access control lists (ACLs)

You supply these values with the vserver cifs share access-control create command.

Field	Description	Your value
-vserver	The name of the SVM on which to create the SMB ACL.	
-share	The name of the SMB share on which to create.	
-user-group-type	The type of the user or group to add to the share's ACL. The default type is windows	windows
-user-or-group	The user or group to add to the share's ACL. If you specify the user name, you must include the user's domain using the "domain\username" format.	
-permission	Specifies the permissions for the user or group.	[No_access Read Change Full_Control]

Configure SMB access to an SVM

Configure SMB access to an SVM

If you do not already have an SVM configured for SMB client access, you must either create and configure a new SVM or configure an existing SVM. Configuring SMB involves opening SVM root volume access, creating an SMB server, creating a LIF, enabling host-name resolution, configuring name services, and if desired, enabling Kerberos security.

Create an SVM

If you do not already have at least one SVM in a cluster to provide data access to SMB clients, you must create one.

Steps

1. Create an SVM: `vserver create -vserver vserver_name -rootvolume root_volume_name -aggregate aggregate_name -rootvolume-security-style ntfs -language C.UTF-8 -ipspace ipspace_name`
 - Use the NTFS setting for the `-rootvolume-security-style` option.
 - Use the default C.UTF-8 `-language` option.
 - The `ipspace` setting is optional.
2. Verify the configuration and status of the newly created SVM: `vserver show -vserver vserver_name`

The `Allowed Protocols` field must include CIFS. You can edit this list later.

The `Vserver Operational State` field must display the `running state`. If it displays the `initializing state`, it means that some intermediate operation such as root volume creation failed, and you must delete the SVM and re-create it.

Examples

The following command creates an SVM for data access in the IPspace ipspaceA:

```
cluster1::> vserver create -vserver vs1.example.com -rootvolume root_vs1  
-aggregate aggr1  
-rootvolume-security-style ntfs -language C.UTF-8 -ipspace ipspaceA  
  
[Job 2059] Job succeeded:  
Vserver creation completed
```

The following command shows that an SVM was created with a root volume of 1 GB, and it was started automatically and is in `running state`. The root volume has a default export policy that does not include any rules, so the root volume is not exported upon creation.

```
cluster1::> vserver show -vserver vs1.example.com
                           Vserver: vs1.example.com
                           Vserver Type: data
                           Vserver Subtype: default
                           Vserver UUID: b8375669-19b0-11e5-b9d1-
00a0983d9736
                           Root Volume: root_vs1
                           Aggregate: aggr1
                           NIS Domain: -
                           Root Volume Security Style: ntfs
                           LDAP Client: -
                           Default Volume Language Code: C.UTF-8
                           Snapshot Policy: default
                           Comment:
                           Quota Policy: default
                           List of Aggregates Assigned: -
                           Limit on Maximum Number of Volumes allowed: unlimited
                           Vserver Admin State: running
                           Vserver Operational State: running
                           Vserver Operational State Stopped Reason: -
                           Allowed Protocols: nfs, cifs, fcp, iscsi, ndmp
                           Disallowed Protocols: -
                           QoS Policy Group: -
                           Config Lock: false
                           IPspace Name: ipspaceA
```

Verify that the SMB protocol is enabled on the SVM

Before you can configure and use SMB on SVMs, you must verify that the protocol is enabled.

About this task

This is typically done during SVM setup, but if you did not enable the protocol during setup, you can enable it later by using the `vserver add-protocols` command.

You cannot add or remove a protocol from a LIF once it is created.

You can also disable protocols on SVMs using the `vserver remove-protocols` command.

Steps

1. Check which protocols are currently enabled and disabled for the SVM: `vserver show -vserver vserver_name -protocols`

You can also use the `vserver show-protocols` command to view the currently enabled protocols on all SVMs in the cluster.

2. If necessary, enable or disable a protocol:

- To enable the SMB protocol: `vserver add-protocols -vserver vserver_name -protocols cifs`
- To disable a protocol: `vserver remove-protocols -vserver vserver_name -protocols protocol_name[,protocol_name,...]`

3. Confirm that the enabled and disabled protocols were updated correctly: `vserver show -vserver vserver_name -protocols`

Example

The following command displays which protocols are currently enabled and disabled (allowed and disallowed) on the SVM named vs1:

```
vs1::> vserver show -vserver vs1.example.com -protocols
Vserver          Allowed Protocols      Disallowed Protocols
-----
vs1.example.com    cifs                  nfs, fcp, iscsi, ndmp
```

The following command allows access over SMB by adding `cifs` to the list of enabled protocols on the SVM named vs1:

```
vs1::> vserver add-protocols -vserver vs1.example.com -protocols cifs
```

Open the export policy of the SVM root volume

The default export policy of the SVM root volume must include a rule to allow all clients open access through SMB. Without such a rule, all SMB clients are denied access to the SVM and its volumes.

About this task

When a new SVM is created, a default export policy (called `default`) is created automatically for the root volume of the SVM. You must create one or more rules for the default export policy before clients can access data on the SVM.

You should verify that all SMB access is open in the default export policy, and later restrict access to individual volumes by creating custom export policies for individual volumes or qtrees.

Steps

1. If you are using an existing SVM, check the default root volume export policy: `vserver export-policy rule show`

The command output should be similar to the following:

```

cluster::> vserver export-policy rule show -vserver vs1.example.com
-policynname default -instance

                                Vserver: vs1.example.com
                                Policy Name: default
                                Rule Index: 1
                                Access Protocol: cifs
Client Match Hostname, IP Address, Netgroup, or Domain: 0.0.0.0/0
                                RO Access Rule: any
                                RW Access Rule: any
User ID To Which Anonymous Users Are Mapped: 65534
                                Superuser Security Types: any
                                Honor SetUID Bits in SETATTR: true
                                Allow Creation of Devices: true

```

If such a rule exists that allows open access, this task is complete. If not, proceed to the next step.

2. Create an export rule for the SVM root volume: `vserver export-policy rule create -vserver vserver_name -policynname default -ruleindex 1 -protocol cifs -clientmatch 0.0.0.0/0 -rorule any -rwrule any -superuser any`
3. Verify rule creation by using the `vserver export-policy rule show` command.

Results

Any SMB client can now access any volume or qtree created on the SVM.

Create a LIF

A LIF is an IP address associated with a physical or logical port. If there is a component failure, a LIF can fail over to or be migrated to a different physical port, thereby continuing to communicate with the network.

Before you begin

- The underlying physical or logical network port must have been configured to the administrative `up` status.
- If you are planning to use a subnet name to allocate the IP address and network mask value for a LIF, the subnet must already exist.

Subnets contain a pool of IP addresses that belong to the same layer 3 subnet. They are created using the `network subnet create` command.

- The mechanism for specifying the type of traffic handled by a LIF has changed. For ONTAP 9.5 and earlier, LIFs used roles to specify the type of traffic it would handle. Beginning with ONTAP 9.6, LIFs use service policies to specify the type of traffic it would handle.

About this task

- You can create both IPv4 and IPv6 LIFs on the same network port.
- If you have a large number of LIFs in your cluster, you can verify the LIF capacity supported on the cluster by using the `network interface capacity show` command and the LIF capacity supported on each

node by using the network interface capacity details show command (at the advanced privilege level).

- Beginning with ONTAP 9.7, if other LIFs already exist for the SVM in the same subnet, you do not need to specify the home port of the LIF. ONTAP automatically chooses a random port on the specified home node in the same broadcast domain as the other LIFs already configured in the same subnet.

Beginning with ONTAP 9.4, FC-NVMe is supported. If you are creating an FC-NVMe LIF you should be aware of the following:

- The NVMe protocol must be supported by the FC adapter on which the LIF is created.
- FC-NVMe can be the only data protocol on data LIFs.
- One LIF handling management traffic must be configured for every storage virtual machine (SVM) supporting SAN.
- NVMe LIFs and namespaces must be hosted on the same node.
- Only one NVMe LIF handling data traffic can be configured per SVM

Steps

1. Create a LIF:

```
network interface create -vserver vserver_name -lif lif_name -role data -data
-protocol cifs -home-node node_name -home-port port_name {-address IP_address
-netmask IP_address | -subnet-name subnet_name} -firewall-policy data -auto
-revert {true|false}
```

ONTAP 9.5 and earlier

```
network interface create -vserver vserver_name -lif lif_name -role data -data
-protocol cifs -home-node node_name -home-port port_name {-address IP_address
-netmask IP_address | -subnet-name subnet_name} -firewall-policy data -auto
-revert {true|false}
```

ONTAP 9.6 and later

```
network interface create -vserver vserver_name -lif lif_name -service-policy
service_policy_name -home-node node_name -home-port port_name {-address
IP_address -netmask IP_address | -subnet-name subnet_name} -firewall-policy
data -auto-revert {true|false}
```

- The `-role` parameter is not required when creating a LIF using a service policy (beginning with ONTAP 9.6).
- The `-data-protocol` parameter must be specified when the LIF is created, and cannot be modified later without destroying and re-creating the data LIF.

The `-data-protocol` parameter is not required when creating a LIF using a service policy (beginning with ONTAP 9.6).

- `home-node` is the node to which the LIF returns when the `network interface revert` command is run on the LIF.

You can also specify whether the LIF should automatically revert to the home-node and home-port with the `-auto-revert` option.

- `-home-port` is the physical or logical port to which the LIF returns when the `network interface revert` command is run on the LIF.
- You can specify an IP address with the `-address` and `-netmask` options, or you enable allocation from a subnet with the `-subnet_name` option.
- When using a subnet to supply the IP address and network mask, if the subnet was defined with a gateway, a default route to that gateway is added automatically to the SVM when a LIF is created using that subnet.
- If you assign IP addresses manually (without using a subnet), you might need to configure a default route to a gateway if there are clients or domain controllers on a different IP subnet. The `network route create` man page contains information about creating a static route within an SVM.
- For the `-firewall-policy` option, use the same default data as the LIF role.

You can create and add a custom firewall policy later if desired.

- `-auto-revert` allows you to specify whether a data LIF is automatically reverted to its home node under circumstances such as startup, changes to the status of the management database, or when the network connection is made. The default setting is `false`, but you can set it to `false` depending on network management policies in your environment.

2. Verify that the LIF was created successfully:

```
network interface show
```

3. Verify that the configured IP address is reachable:

To verify an...	Use...
IPv4 address	<code>network ping</code>
IPv6 address	<code>network ping6</code>

Examples

The following command creates a LIF and specifies the IP address and network mask values using the `-address` and `-netmask` parameters:

```
network interface create -vserver vs1.example.com -lif datalif1 -role data  
-data-protocol cifs -home-node node-4 -home-port e1c -address 192.0.2.145  
-netmask 255.255.255.0 -firewall-policy data -auto-revert true
```

The following command creates a LIF and assigns IP address and network mask values from the specified subnet (named `client1_sub`):

```
network interface create -vserver vs3.example.com -lif datalif3 -role data
-data-protocol cifs -home-node node-3 -home-port e1c -subnet-name
client1_sub -firewall-policy data -auto-revert true
```

The following command shows all the LIFs in cluster-1. Data LIFs datalif1 and datalif3 are configured with IPv4 addresses, and datalif4 is configured with an IPv6 address:

```
network interface show

      Logical          Status        Network          Current       Current Is
Vserver     Interface    Admin/Oper Address/Mask    Node        Port

```

The following command shows how to create a NAS data LIF that is assigned with the default-data-files service policy:

```
network interface create -vserver vs1 -lif lif2 -home-node node2 -homeport  
e0d -service-policy default-data-files -subnet-name ipspace1
```

Enable DNS for host-name resolution

You can use the `vserver services name-service dns` command to enable DNS on an SVM, and configure it to use DNS for host-name resolution. Host names are resolved using external DNS servers.

Before you begin

A site-wide DNS server must be available for host name lookups.

You should configure more than one DNS server to avoid a single-point-of-failure. The `vserver services name-service dns create` command issues a warning if you enter only one DNS server name.

About this task

The *Network Management Guide* contains information about configuring dynamic DNS on the SVM.

Steps

1. Enable DNS on the SVM: `vserver services name-service dns create -vserver vserver_name -domains domain_name -name-servers ip_addresses -state enabled`

The following command enables external DNS server servers on the SVM vs1:

```
vserver services name-service dns create -vserver vs1.example.com  
-domains example.com -name-servers 192.0.2.201,192.0.2.202 -state  
enabled
```

Beginning with ONTAP 9.2, the `vserver services name-service dns create` command performs an automatic configuration validation and reports an error message if ONTAP cannot contact the name server.

2. Display the DNS domain configurations by using the `vserver services name-service dns show` command.

The following command displays the DNS configurations for all SVMs in the cluster:

```
vserver services name-service dns show
```

Vserver	State	Domains	Name
			Servers
<hr/>			
cluster1	enabled	example.com	192.0.2.201, 192.0.2.202
vs1.example.com	enabled	example.com	192.0.2.201, 192.0.2.202

The following command displays detailed DNS configuration information for SVM vs1:

```
vserver services name-service dns show -vserver vs1.example.com
    Vserver: vs1.example.com
    Domains: example.com
    Name Servers: 192.0.2.201, 192.0.2.202
    Enable/Disable DNS: enabled
    Timeout (secs): 2
    Maximum Attempts: 1
```

3. Validate the status of the name servers by using the vserver services name-service dns check command.

The vserver services name-service dns check command is available beginning with ONTAP 9.2.

```
vserver services name-service dns check -vserver vs1.example.com

Vserver          Name Server      Status       Status Details
-----          -----        -----
vs1.example.com   10.0.0.50      up           Response time (msec): 2
vs1.example.com   10.0.0.51      up           Response time (msec): 2
```

Set up an SMB server in an Active Directory domain

Configure time services

Before creating an SMB server in an Active Domain controller, you must ensure that the cluster time and the time on the domain controllers of the domain to which the SMB server will belong matches to within five minutes.

About this task

You should configure cluster NTP services to use the same NTP servers for time synchronization that the Active Directory domain uses.

Beginning with ONTAP 9.5, you can set up your NTP server with symmetric authentication.

Steps

1. Configure time services by using the cluster time-service ntp server create command.

- To configure time services without symmetric authentication enter the following command: cluster time-service ntp server create -server server_ip_address
- To configure time services with symmetric authentication, enter the following command: cluster time-service ntp server create -server server_ip_address -key-id key_id
cluster time-service ntp server create -server 10.10.10.1 cluster time-service ntp server create -server 10.10.10.2

2. Verify that time services are set up correctly by using the `cluster time-service ntp server show` command.

```
cluster time-service ntp server show
```

Server	Version
10.10.10.1	auto
10.10.10.2	auto

Commands for managing symmetric authentication on NTP servers

Beginning with ONTAP 9.5, Network Time Protocol (NTP) version 3 is supported. NTPv3 includes symmetric authentication using SHA-1 keys which increases network security.

To do this...	Use this command...
Configure an NTP server without symmetric authentication	<code>cluster time-service ntp server create -server server_name</code>
Configure an NTP server with symmetric authentication	<code>cluster time-service ntp server create -server server_ip_address -key-id key_id</code>
Enable symmetric authentication for an existing NTP server An existing NTP server can be modified to enable authentication by adding the required key-id.	<code>cluster time-service ntp server modify -server server_name -key-id key_id</code>
Configure a shared NTP key	<code>cluster time-service ntp key create -id shared_key_id -type shared_key_type -value shared_key_value</code> <div style="margin-top: 10px;"> i Shared keys are referred to by an ID. The ID, its type, and value must be identical on both the node and the NTP server </div>
Configure an NTP server with an unknown key ID	<code>cluster time-service ntp server create -server server_name -key-id key_id</code>
Configure a server with a key ID not configured on the NTP server.	<code>cluster time-service ntp server create -server server_name -key-id key_id</code> <div style="margin-top: 10px;"> i The key ID, type, and value must be identical to the key ID, type, and value configured on the NTP server. </div>

To do this...	Use this command...
Disable symmetric authentication	<code>cluster time-service ntp server modify -server server_name -authentication disabled</code>

Create an SMB server in an Active Directory domain

You can use the `vserver cifs create` command to create an SMB server on the SVM and specify the Active Directory (AD) domain to which it belongs.

Before you begin

The SVM and LIFs that you are using to serve data must have been configured to allow the SMB protocol. The LIFs must be able to connect to the DNS servers that are configured on the SVM and to an AD domain controller of the domain to which you want to join the SMB server.

Any user who is authorized to create machine accounts in the AD domain to which you are joining the SMB server can create the SMB server on the SVM. This can include users from other domains.

Beginning with ONTAP 9.7, your AD administrator can provide you with a URI to a keytab file as an alternative to providing you with a name and password to a privileged Windows account. When you receive the URI, include it in the `-keytab-uri` parameter with the `vserver cifs` commands.

About this task

When creating an SMB server in an Activity Directory domain:

- You must use the fully qualified domain name (FQDN) when specifying the domain.
- The default setting is to add the SMB server machine account to the Active Directory CN=Computer object.
- You can choose to add the SMB server to a different organizational unit (OU) by using the `-ou` option.
- You can optionally choose to add a comma-delimited list of one or more NetBIOS aliases (up to 200) for the SMB server.

Configuring NetBIOS aliases for an SMB server can be useful when you are consolidating data from other file servers to the SMB server and want the SMB server to respond to the original servers' names.

The `vserver cifs` man pages contain additional optional parameters and naming requirements.

Beginning with ONTAP 9.1, you can enable SMB version 2.0 to connect to a domain controller (DC). Doing so is necessary if you have disabled SMB 1.0 on domain controllers. Beginning with ONTAP 9.2, SMB 2.0 is enabled by default.

Beginning with ONTAP 9.8, you can specify that connections to domain controllers be encrypted. ONTAP requires encryption for domain controller communications when the `-encryption-required-for-dc-connection` option is set to `true`; the default is `false`. When the option is set, only the SMB3 protocol will be used for ONTAP-DC connections, because encryption is only supported by SMB3. .

[SMB management](#) contains more information about SMB server configuration options.

Steps

1. Verify that SMB is licensed on your cluster: `system license show -package cifs`

If it is not, contact your sales representative.

A CIFS license is not required if the SMB server will be used for authentication only.

2. Create the SMB server in an AD domain: `vserver cifs create -vserver vserver_name -cifs-server smb_server_name -domain FQDN [-ou organizational_unit][-netbios-aliases NetBIOS_name, ...] [-keytab-uri {(ftp|http)://hostname|IP_address}] [-comment text]`

When joining a domain, this command might take several minutes to finish.

The following command creates the SMB server “`smb_server01`” in the domain “`example.com`”:

```
cluster1::> vserver cifs create -vserver vs1.example.com -cifs-server  
smb_server01 -domain example.com
```

The following command creates the SMB server “`smb_server02`” in the domain “`mydomain.com`” and authenticates the ONTAP administrator with a keytab file:

```
cluster1::> vserver cifs create -vserver vs1.mydomain.com -cifs-server  
smb_server02 -domain mydomain.com -keytab-uri  
http://admin.mydomain.com/ontap1.keytab
```

3. Verify the SMB server configuration by using the `vserver cifs show` command.

In this example, the command output shows that an SMB server named “`SMB_SERVER01`” was created on SVM `vs1.example.com`, and was joined to the “`example.com`” domain.

```
cluster1::> vserver cifs show -vserver vs1  
  
Vserver: vs1.example.com  
CIFS Server NetBIOS Name: SMB_SERVER01  
NetBIOS Domain/Workgroup Name: EXAMPLE  
Fully Qualified Domain Name: EXAMPLE.COM  
Default Site Used by LIFs Without Site Membership:  
Authentication Style: domain  
CIFS Server Administrative Status: up  
CIFS Server Description: -  
List of NetBIOS Aliases: -
```

4. If desired, enable encrypted communication with the domain controller (ONTAP 9.8 and later): `vserver cifs security modify -vserver svm_name -encryption-required-for-dc-connection true`

Examples

The following command creates a SMB server named “smb_server02” on SVM vs2.example.com in the “example.com” domain. The machine account is created in the “OU=eng,OU=corp,DC=example,DC=com” container. The SMB server is assigned a NetBIOS alias.

```
cluster1::> vserver cifs create -vserver vs2.example.com -cifs-server  
smb_server02 -domain example.com -ou OU=eng,OU=corp -netbios-aliases  
old_cifs_server01

cluster1::> vserver cifs show -vserver vs1
                                         Vserver: vs2.example.com
                                         CIFS Server NetBIOS Name: SMB_SERVER02
                                         NetBIOS Domain/Workgroup Name: EXAMPLE
                                         Fully Qualified Domain Name: EXAMPLE.COM
Default Site Used by LIFs Without Site Membership:
                                         Authentication Style: domain
                                         CIFS Server Administrative Status: up
                                         CIFS Server Description: -
                                         List of NetBIOS Aliases: OLD_CIFS_SERVER01
```

The following command enables a user from a different domain, in this case an administrator of a trusted domain, to create a SMB server named “smb_server03” on SVM vs3.example.com. The –domain option specifies the name of the home domain (specified in the DNS configuration) in which you want to create the SMB server. The username option specifies the administrator of the trusted domain.

- Home domain: example.com
 - Trusted domain: trust.lab.com
 - Username for the trusted domain: Administrator1

```
cluster1::> vserver cifs create -vserver vs3.example.com -cifs-server  
smb server03 -domain example.com
```

Username: Administrator1@trust.lab.com
Password: . . .

Create keytab files for SMB authentication

Beginning with ONTAP 9.7, ONTAP supports SVM authentication with Active Directory (AD) servers using keytab files. AD administrators generate a keytab file and make it available to ONTAP administrators as a uniform resource identifier (URI), which is supplied when `vserver cifs` commands require Kerberos authentication with the AD domain.

AD administrators can create the keytab files using the standard Windows Server ktpass command. The command should be run on the primary domain where authentication is required. The ktpass command can be used to generate keytab files only for primary domain users; keys generated using trusted-domain users are not supported.

Keytab files are generated for specific ONTAP admin users. As long as the admin user's password does not change, the keys generated for the specific encryption type and domain will not change. Therefore, a new keytab file is required whenever the admin user's password is changed.

The following encryption types are supported:

- AES256-SHA1
- DES-CBC-MD5

ONTAP does not support DES-CBC-CRC encryption type.

- RC4-HMAC

AES256 is the highest encryption type and should be used if enabled on the ONTAP system.

Keytab files can be generated by specifying either the admin password or by using a randomly-generated password. However, at any given time only one password option can be used, because a private key specific to the admin user is needed at the AD server for decrypting the keys inside the keytab file. Any change in the private key for a specific admin will invalidate the keytab file.

Set up an SMB server in a workgroup

Set up an SMB server in a workgroup overview

Setting up an SMB server as a member in a workgroup consists of creating the SMB server, and then creating local users and groups.

You can configure an SMB server in a workgroup when the Microsoft Active Directory domain infrastructure is not available.

An SMB server in workgroup mode supports only NTLM authentication and does not support Kerberos authentication.

Create an SMB server in a workgroup

You can use the `vserver cifs create` command to create an SMB server on the SVM and specify the workgroup to which it belongs.

Before you begin

The SVM and LIFs that you are using to serve data must have been configured to allow the SMB protocol. The LIFs must be able to connect to the DNS servers that are configured on the SVM.

About this task

SMB servers in workgroup mode do not support the following SMB features:

- SMB3 Witness protocol
- SMB3 CA shares
- SQL over SMB
- Folder Redirection
- Roaming Profiles

- Group Policy Object (GPO)
- Volume Snapshot Service (VSS)

The `vserver cifs` man pages contain additional optional configuration parameters and naming requirements.

Steps

1. Verify that SMB is licensed on your cluster: `system license show -package cifs`

If it is not, contact your sales representative.

A CIFS license is not required if the SMB server will be used for authentication only.

2. Create the SMB server in a workgroup: `vserver cifs create -vserver vserver_name -cifs -server cifs_server_name -workgroup workgroup_name [-comment text]`

The following command creates the SMB server “`smb_server01`” in the workgroup “`workgroup01`”:

```
cluster1::> vserver cifs create -vserver vs1.example.com -cifs-server  
SMB_SERVER01 -workgroup workgroup01
```

3. Verify the SMB server configuration by using the `vserver cifs show` command.

In the following example, the command output shows that a SMB server named “`smb_server01`” was created on SVM `vs1.example.com` in the workgroup “`workgroup01`”:

```
cluster1::> vserver cifs show -vserver vs0  
  
Vserver: vs1.example.com  
CIFS Server NetBIOS Name: SMB_SERVER01  
NetBIOS Domain/Workgroup Name: workgroup01  
Fully Qualified Domain Name: -  
Organizational Unit: -  
Default Site Used by LIFs Without Site Membership: -  
Workgroup Name: workgroup01  
Authentication Style: workgroup  
CIFS Server Administrative Status: up  
CIFS Server Description:  
List of NetBIOS Aliases: -
```

After you finish

For a CIFS server in a workgroup, you must create local users, and optionally local groups, on the SVM.

Related information

[SMB management](#)

Create local user accounts

You can create a local user account that can be used to authorize access to data contained in the SVM over an SMB connection. You can also use local user accounts for authentication when creating an SMB session.

About this task

Local user functionality is enabled by default when the SVM is created.

When you create a local user account, you must specify a user name and you must specify the SVM with which to associate the account.

The `vserver cifs users-and-groups local-user` man pages contain details about optional parameters and naming requirements.

Steps

1. Create the local user: `vserver cifs users-and-groups local-user create -vserver vserver_name -user-name user_name optional_parameters`

The following optional parameters might be useful:

- `-full-name`

The user's full name.

- `-description`

A description for the local user.

- `-is-account-disabled {true|false}`

Specifies whether the user account is enabled or disabled. If this parameter is not specified, the default is to enable the user account.

The command prompts for the local user's password.

2. Enter a password for the local user, and then confirm the password.
3. Verify that the user was successfully created: `vserver cifs users-and-groups local-user show -vserver vserver_name`

Example

The following example creates a local user “SMB_SERVER01\sue”, with a full name “Sue Chang”, associated with SVM vs1.example.com:

```
cluster1::> vserver cifs users-and-groups local-user create -vserver  
vs1.example.com -user-name SMB_SERVER01\sue -full-name "Sue Chang"
```

Enter the password:

Confirm the password:

```
cluster1::> vserver cifs users-and-groups local-user show  
Vserver User Name Full Name Description  
-----  
vs1 SMB_SERVER01\Administrator Built-in administrator  
account  
vs1 SMB_SERVER01\sue Sue Chang
```

Create local groups

You can create local groups that can be used for authorizing access to data associated with the SVM over an SMB connection. You can also assign privileges that define what user rights or capabilities a member of the group has.

About this task

Local group functionality is enabled by default when the SVM is created.

When you create a local group, you must specify a name for the group and you must specify the SVM with which to associate the group. You can specify a group name with or without the local domain name, and you can optionally specify a description for the local group. You cannot add a local group to another local group.

The `vserver cifs users-and-groups local-group` man pages contain details about optional parameters and naming requirements.

Steps

1. Create the local group: `vserver cifs users-and-groups local-group create -vserver vserver_name -group-name group_name`

The following optional parameter might be useful:

- `-description`

A description for the local group.

2. Verify that the group was successfully created: `vserver cifs users-and-groups local-group show -vserver vserver_name`

Example

The following example creates a local group “SMB_SERVER01\engineering” associated with SVM vs1:

```

cluster1::> vserver cifs users-and-groups local-group create -vserver
vs1.example.com -group-name SMB_SERVER01\engineering

cluster1::> vserver cifs users-and-groups local-group show -vserver
vs1.example.com
Vserver           Group Name          Description
-----
vs1.example.com  BUILTIN\Administrators  Built-in Administrators
group
vs1.example.com  BUILTIN\Backup Operators  Backup Operators group
vs1.example.com  BUILTIN\Power Users      Restricted administrative
privileges
vs1.example.com  BUILTIN\Users          All users
vs1.example.com  SMB_SERVER01\engineering
vs1.example.com  SMB_SERVER01\sales

```

After you finish

You must add members to the new group.

Manage local group membership

You can manage local group membership by adding and removing local or domain users, or adding and removing domain groups. This is useful if you want to control access to data based on access controls placed on the group, or if you want users to have privileges associated with that group.

About this task

If you no longer want a local user, domain user, or domain group to have access rights or privileges based on membership in a group, you can remove the member from the group.

You must keep the following in mind when adding members to a local group:

- You cannot add users to the special *Everyone* group.
- You cannot add a local group to another local group.
- To add a domain user or group to a local group, ONTAP must be able to resolve the name to a SID.

You must keep the following in mind when removing members from a local group:

- You cannot remove members from the special *Everyone* group.
- To remove a member from a local group, ONTAP must be able to resolve their name to a SID.

Steps

1. Add a member to or remove a member from a group.

- Add a member: `vserver cifs users-and-groups local-group add-members -vserver vserver_name -group-name group_name -member-names name[,...]`

You can specify a comma-delimited list of local users, domain users, or domain groups to add to the

specified local group.

- Remove a member: `vserver cifs users-and-groups local-group remove-members -vserver vserver_name -group-name group_name -member-names name[,...]`

You can specify a comma-delimited list of local users, domain users, or domain groups to remove from the specified local group.

Examples

The following example adds a local user “SMB_SERVER01\sue” to the local group “SMB_SERVER01\engineering” on SVM vs1.example.com:

```
cluster1::> vserver cifs users-and-groups local-group add-members -vserver
vs1.example.com -group-name SMB_SERVER01\engineering -member-names
SMB_SERVER01\sue
```

The following example removes the local users “SMB_SERVER01\sue” and “SMB_SERVER01\james” from the local group “SMB_SERVER01\engineering” on SVM vs1.example.com:

```
cluster1::> vserver cifs users-and-groups local-group remove-members
-vserver vs1.example.com -group-name SMB_SERVER\engineering -member-names
SMB_SERVER\sue,SMB_SERVER\james
```

Verify enabled SMB versions

Your ONTAP 9 release determines which SMB versions are enabled by default for connections with clients and domain controllers. You should verify that the SMB server supports the clients and functionality required in your environment.

About this task

For connections with both clients and domain controllers, you should enable SMB 2.0 and later whenever possible. For security reasons, you should avoid using SMB 1.0, and you should disable it if you have verified that it is not required in your environment.

In ONTAP 9, SMB versions 2.0 and later are enabled by default for client connections, but the version of SMB 1.0 enabled by default depends on your ONTAP release.

- Beginning with ONTAP 9.1 P8, SMB 1.0 can be disabled on SVMs.

The `-smb1-enabled` option to the `vserver cifs options modify` command enables or disables SMB 1.0.

- Beginning with ONTAP 9.3, it is disabled by default on new SVMs.

If your SMB server is in an Active Directory (AD) domain, you can enable SMB 2.0 to connect to a domain controller (DC) beginning with ONTAP 9.1. Doing so is necessary if you have disabled SMB 1.0 on DCs. Beginning with ONTAP 9.2, SMB 2.0 is enabled by default for DC connections.

If `-smb1-enabled-for-dc-connections` is set to `false` while `-smb1-enabled` is set to `true`, ONTAP denies SMB 1.0 connections as the client, but continues to accept inbound SMB 1.0 connections as the server.

[SMB management](#) contains details about supported SMB versions and functionality.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Verify which SMB versions are enabled: `vserver cifs options show`

You can scroll down the list to view the SMB versions enabled for client connections, and if you are configuring an SMB server in an AD domain, for AD domain connections.

3. Enable or disable the SMB protocol for client connections as required:

- To enable an SMB version: `vserver cifs options modify -vserver vserver_namesmb_version true`
- To disable an SMB version: `vserver cifs options modify -vserver vserver_namesmb_version false`
Possible values for `smb_version`:
 - `-smb1-enabled`
 - `-smb2-enabled`
 - `-smb3-enabled`
 - `-smb31-enabled`

The following command enables SMB 3.1 on SVM vs1.example.com:

```
cluster1::>*> vserver cifs options modify -vserver vs1.example.com -smb31-enabled true
```

4. If your SMB server is in an Active Directory domain, enable or disable the SMB protocol for DC connections as required:

- To enable an SMB version: `vserver cifs security modify -vserver vserver_name -smb2-enabled-for-dc-connections true`
- To disable an SMB version: `vserver cifs security modify -vserver vserver_name -smb2-enabled-for-dc-connections false`

5. Return to the admin privilege level: `set -privilege admin`

Map the SMB server on the DNS server

Your site's DNS server must have an entry pointing the SMB server name, and any NetBIOS aliases, to the IP address of the data LIF so that Windows users can map a drive to the SMB server name.

Before you begin

You must have administrative access to your site's DNS server. If you do not have administrative access, you

must ask the DNS administrator to perform this task.

About this task

If you use NetBIOS aliases for the SMB server name, it is a best practice to create DNS server entry points for each alias.

Steps

1. Log in to the DNS server.
2. Create forward (A - Address record) and reverse (PTR - Pointer record) lookup entries to map the SMB server name to the IP address of the data LIF.
3. If you use NetBIOS aliases, create an Alias canonical name (CNAME resource record) lookup entry to map each alias to the IP address of the SMB server's data LIF.

Results

After the mapping is propagated across the network, Windows users can map a drive to the SMB server name or its NetBIOS aliases.

Configure SMB client access to shared storage

Configure SMB client access to shared storage

To provide SMB client access to shared storage on an SVM, you must create a volume or qtree to provide a storage container, and then create or modify a share for that container. You can then configure share and file permissions, and test access from client systems.

Before you begin

- SMB must be completely set up on the SVM.
- Any updates to your name services configuration must be complete.
- Any additions or modifications to an Active Directory domain or workgroup configuration must be complete.

Create a volume or qtree storage container

Create a volume

You can create a volume and specify its junction point and other properties by using the `volume create` command.

Before you begin

The SVM security style must be NTFS, and SMB should be set up and running.

About this task

A volume must include a *junction path* for its data to be made available to clients. You can specify the junction path when you create a new volume. If you create a volume without specifying a junction path, you must *mount* the volume in the SVM namespace using the `volume mount` command.

Steps

1. Create the volume with a junction point: `volume create -vserver vserver_name -volume volume_name -aggregate aggregate_name -size {integer[KB|MB|GB|TB|PB]} -security-style ntfs -junction-path junction_path`

The choices for `-junction-path` are the following:

- Directly under root, for example, `/new_vol`

You can create a new volume and specify that it be mounted directly to the SVM root volume.

- Under an existing directory, for example, `/existing_dir/new_vol`

You can create a new volume and specify that it be mounted to an existing volume (in an existing hierarchy), expressed as a directory.

If you want to create a volume in a new directory (in a new hierarchy under a new volume), for example, `/new_dir/new_vol`, then you must first create a new parent volume that is junctioned to the SVM root volume. You would then create the new child volume in the junction path of the new parent volume (new directory).

2. Verify that the volume was created with the desired junction point: `volume show -vserver vserver_name -volume volume_name -junction`

Examples

The following command creates a new volume named `users1` on the SVM `vs1.example.com` and the aggregate `aggr1`. The new volume is made available at `/users`. The volume is 750 GB in size, and its volume guarantee is of type `volume` (by default).

```
cluster1::> volume create -vserver vs1.example.com -volume users  
-aggregate aggr1 -size 750g -junction-path /users  
[Job 1642] Job succeeded: Successful

cluster1::> volume show -vserver vs1.example.com -volume users -junction  
Junction Junction  
Vserver Volume Active Junction Path Path Source  
-----  
vs1.example.com users1 true /users RW_volume
```

The following command creates a new volume named “`home4`” on the SVM “`vs1.example.com`” and the aggregate “`aggr1`”. The directory `/eng/` already exists in the namespace for the `vs1` SVM, and the new volume is made available at `/eng/home`, which becomes the home directory for the `/eng/` namespace. The volume is 750 GB in size, and its volume guarantee is of type `volume` (by default).

```

cluster1::> volume create -vserver vs1.example.com -volume home4
-aggregate aggr1 -size 750g -junction-path /eng/home
[Job 1642] Job succeeded: Successful

cluster1::> volume show -vserver vs1.example.com -volume home4 -junction
                Junction          Junction
                Vserver      Volume  Active   Junction Path  Path Source
-----  -----
vs1.example.com    home4     true     /eng/home      RW_volume

```

Create a qtree

You can create a qtree to contain your data and specify its properties by using the `volume qtree create` command.

Before you begin

- The SVM and the volume that will contain the new qtree must already exist.
- The SVM security style must be NTFS, and SMB should be set up and running.

Steps

1. Create the qtree: `volume qtree create -vserver vserver_name { -volume volume_name -qtree qtree_name | -qtree-path qtree path } -security-style ntfs`

You can specify the volume and qtree as separate arguments or specify the qtree path argument in the format `/vol/volume_name/_qtree_name`.

2. Verify that the qtree was created with the desired junction path: `volume qtree show -vserver vserver_name { -volume volume_name -qtree qtree_name | -qtree-path qtree path }`

Example

The following example creates a qtree named qt01 located on SVM vs1.example.com that has a junction path `/vol/data1`:

```

cluster1::> volume qtree create -vserver vs1.example.com -qtree-path
/vol/data1/qt01 -security-style ntfs
[Job 1642] Job succeeded: Successful

cluster1::> volume qtree show -vserver vs1.example.com -qtree-path
/vol/data1/qt01

          Vserver Name: vs1.example.com
          Volume Name: data1
          Qtree Name: qt01
Actual (Non-Junction) Qtree Path: /vol/data1/qt01
          Security Style: ntfs
          Optrack Mode: enable
          Unix Permissions: ---rwxr-xr-x
          Qtree Id: 2
          Qtree Status: normal
          Export Policy: default
Is Export Policy Inherited: true

```

Requirements and considerations for creating an SMB share

Before creating an SMB share, you must understand requirements for share paths and share properties, particularly for home directories.

Creating an SMB share entails specifying a directory path structure (using the `-path` option in the `vserver cifs share create` command) that clients will access. The directory path corresponds to the junction path for a volume or qtree that you created in the SVM namespace. The directory path and corresponding junction path must exist before creating your share.

Share paths have the following requirements:

- A directory path name can be up to 255 characters long.
- If there is a space in the path name, the entire string must be put in quotes (for example, `"/new volume/mount here"`).
- If the UNC path (`\servername\sharename\filepath`) of the share contains more than 256 characters (excluding the initial `"\"` in the UNC path), then the **Security** tab in the Windows Properties box is unavailable.

This is a Windows client issue rather than an ONTAP issue. To avoid this issue, do not create shares with UNC paths with more than 256 characters.

Share property defaults can be changed:

- The default initial properties for all shares are `oplocks`, `browsable`, `changenotify`, and `show-previous-versions`.
- It is optional to specify share properties when you create a share.

However, if you do specify share properties when you create the share, the defaults are not used. If you use the `-share-properties` parameter when you create a share, you must specify all of the share properties that you want to apply to the share using a comma-delimited list.

- To designate a home directory share, use the `homedirectory` property.

This feature enables you to configure a share that maps to different directories based on the user that connects to it and a set of variables. Instead of having to create separate shares for each user, you can configure a single share with a few home directory parameters to define a user's relationship between an entry point (the share) and their home directory (a directory on the SVM).

You cannot add or remove this property after creating the share.

Home directory shares have the following requirements:

- Before creating SMB home directories, you must add at least one home directory search path by using the `vserver cifs home-directory search-path add` command.
- Home directory shares specified by the value of `homedirectory` on the `-share-properties` parameter must include the `%w` (Windows user name) dynamic variable in the share name.

The share name can additionally contain the `%d` (domain name) dynamic variable (for example, `%d/%w`) or a static portion in the share name (for example, `home1_%w`).

- If the share is used by administrators or users to connect to other users' home directories (using options to the `vserver cifs home-directory modify` command), the dynamic share name pattern must be preceded by a tilde (~).

[SMB management](#) and [vserver cifs share man](#) pages have additional information.

Create an SMB share

You must create an SMB share before you can share data from an SMB server with SMB clients. When you create a share, you can set share properties, such as designating the share as a home directory. You can also customize the share by configuring optional settings.

Before you begin

The directory path for the volume or qtree must exist in the SVM namespace before creating the share.

About this task

When you create a share, the default share ACL (default share permissions) is Everyone / Full Control. After testing access to the share, you should remove the default share ACL and replace it with a more secure alternative.

Steps

1. If necessary, create the directory path structure for the share.

The `vserver cifs share create` command checks the path specified in the `-path` option during share creation. If the specified path does not exist, the command fails.

2. Create an SMB share associated with the specified SVM: `vserver cifs share create -vserver`

```
vserver_name -share-name share_name -path path [-share-properties  
share_properties,...] [other_attributes] [-comment text]
```

3. Verify that the share was created:vserver cifs share show -share-name share_name

Examples

The following command creates an SMB share named “SHARE1” on SVM vs1.example.com. Its directory path is /users, and it is created with default properties.

```
cluster1::> vserver cifs share create -vserver vs1.example.com -share-name  
SHARE1 -path /users

cluster1::> vserver cifs share show -share-name SHARE1

Vserver      Share      Path      Properties Comment    ACL
-----  -----  -----  -----  -----  -----
vs1.example.com  SHARE1  /users  oplocks   -        Everyone / Full
Control
                                browsable
                                changenotify
                                show-previous-versions
```

Verify SMB client access

You should verify that you have configured SMB correctly by accessing and writing data to the share. You should test access using the SMB server name and any NetBIOS aliases.

Steps

1. Log in to a Windows client.

2. Test access using the SMB server name:

- a. In Windows Explorer, map a drive to the share in the following format: \\SMB_Server_Name\Share_Name

If the mapping is not successful, it is possible that the DNS mapping has not yet propagated throughout the network. You must test access using the SMB server name later.

If the SMB server is named vs1.example.com and the share is named SHARE1, you should enter the following: \\vs0.example.com\SHARE1

- b. On the newly created drive, create a test file, and then delete the file.

You have verified write access to the share using the SMB server name.

3. Repeat Step 2 for any NetBIOS aliases.

Create SMB share access control lists

Configuring share permissions by creating access control lists (ACLs) for SMB shares enables you to control the level of access to a share for users and groups.

Before you begin

You must have decided which users or groups will be given access to the share.

About this task

You can configure share-level ACLs by using local or domain Windows user or group names.

Before creating a new ACL, you should delete the default share ACL Everyone / Full Control, which poses a security risk.

In workgroup mode, the local domain name is the SMB server name.

Steps

1. Delete the default share ACL:
`vserver cifs share access-control delete -vserver vserver_name -share share_name -user-or-group everyone`
2. Configure the new ACL:

If you want to configure ACLs by using a...	Enter the command...
Windows user	<code>vserver cifs share access-control create -vserver vserver_name -share share_name -user-group-type windows -user-or-group Windows_domain_name\\user_name -permission access_right</code>
Windows group	<code>vserver cifs share access-control create -vserver vserver_name -share share_name -user-group-type windows -user-or-group Windows_group_name -permission access_right</code>

3. Verify that the ACL applied to the share is correct by using the `vserver cifs share access-control show` command.

Example

The following command gives Change permissions to the "Sales Team" Windows group for the "sales" share on the "vs1.example.com`"SVM:

```

cluster1::> vserver cifs share access-control create -vserver
vs1.example.com -share sales -user-or-group "Sales Team" -permission
Change

cluster1::> vserver cifs share access-control show
      Share          User/Group          User/Group  Access
Vserver      Name          Name          Type
Permission
-----
-----
vs1.example.com   c$          BUILTIN\Administrators  windows
Full_Control
vs1.example.com   sales        DOMAIN\"Sales Team"    windows      Change

```

The following commands give Change permission to the local Windows group named “Tiger Team” and Full_Control permission to the local Windows user named “Sue Chang” for the “datavol5” share on the “vs1” SVM:

```

cluster1::> vserver cifs share access-control create -vserver vs1 -share
datavol5 -user-group-type windows -user-or-group "Tiger Team" -permission
Change

cluster1::> vserver cifs share access-control create -vserver vs1 -share
datavol5 -user-group-type windows -user-or-group "Sue Chang" -permission
Full_Control

cluster1::> vserver cifs share access-control show -vserver vs1
      Share          User/Group          User/Group  Access
Vserver      Name          Name          Type
Permission
-----
-----
vs1           c$          BUILTIN\Administrators  windows
Full_Control
vs1           datavol5        DOMAIN\"Tiger Team"    windows      Change
vs1           datavol5        DOMAIN\"Sue Chang"    windows
Full_Control

```

Configure NTFS file permissions in a share

To enable file access to the users or groups who have access to a share, you must configure NTFS file permissions on files and directories in that share from a Windows client.

Before you begin

The administrator performing this task must have sufficient NTFS permissions to change permissions on the selected objects.

About this task

[SMB management](#) and your Windows documentation contain information about how to set standard and advanced NTFS permissions.

Steps

1. Log in to a Windows client as an administrator.
2. From the **Tools** menu in Windows Explorer, select **Map network drive**.
3. Complete the **Map Network Drive** box:
 - a. Select a **Drive** letter.
 - b. In the **Folder** box, type the SMB server name containing the share that contains the data to which you want to apply permissions and the name of the share.

If your SMB server name is `SMB_SERVER01` and your share is named “`SHARE1`”, you would enter `\SMB_SERVER01\SHARE1`.

You can specify the IP address of the data interface for the SMB server instead of the SMB server name.

- c. Click **Finish**.

The drive you selected is mounted and ready with the Windows Explorer window displaying files and folders contained within the share.

4. Select the file or directory for which you want to set NTFS file permissions.
5. Right-click the file or directory, and then select **Properties**.
6. Select the **Security** tab.

The Security tab displays the list of users and groups for which NTFS permission are set. The Permissions for <Object> box displays a list of Allow and Deny permissions in effect for the selected user or group.

7. Click **Edit**.

The Permissions for <Object> box opens.

8. Perform the desired actions:

If you want to....	Do the following...
Set standard NTFS permissions for a new user or group	<ol style="list-style-type: none">a. Click Add. The Select User, Computers, Service Accounts, or Groups window opens.b. In the Enter the object names to select box, type the name of the user or group on which you want to add NTFS permission.c. Click OK.

If you want to....	Do the following...
Change or remove standard NTFS permissions from a user or group	In the Group or user names box, select the user or group that you want to change or remove.

9. Perform the desired actions:

If you want to...	Do the following
Set standard NTFS permissions for a new or existing user or group	In the Permissions for <Object> box, select the Allow or Deny boxes for the type of access that you want to allow or not allow for the selected user or group.
Remove a user or group	Click Remove .

If some or all of the standard permission boxes are not selectable, it is because the permissions are inherited from the parent object. The **Special permissions** box is not selectable. If it is selected, it means that one or more of the granular advanced rights has been set for the selected user or group.

10. After you finish adding, removing, or editing NTFS permissions on that object, click **OK**.

Verify user access

You should test that the users you configured can access the SMB share and the files it contains.

Steps

1. On a Windows client, log in as one of the users who now has access to the share.
2. From the **Tools** menu in Windows Explorer, select **Map network drive**.
3. Complete the **Map Network Drive** box:
 - a. Select a **Drive** letter.
 - b. In the **Folder** box, type the share name you will provide to users.

If your SMB server name is **SMB_SERVER01** and your share is named “**SHARE1**”, you would enter **\\\SMB_SERVER01\share1**.

- c. Click **Finish**.

The drive you selected is mounted and ready with the Windows Explorer window displaying files and folders contained within the share.

4. Create a test file, verify that it exists, write text to it, and then remove the test file.

Manage SMB with the CLI

SMB reference overview

ONTAP file access features are available for the SMB protocol. You can enable a CIFS server, create shares, and enable Microsoft services.

SMB (Server Message Block) refers to modern dialects of the Common Internet File System (CIFS) protocol. You will still see CIFS in the ONTAP command-line interface (CLI) and in OnCommand management tools.

You should use these procedures under the following circumstances:

- You want to understand the range of ONTAP SMB protocol capabilities.
- You want to perform less common configuration and maintenance tasks, not basic SMB configuration.
- You want to use the command-line interface (CLI), not System Manager or an automated scripting tool.

SMB server support

SMB server support overview

You can enable and configure SMB servers on storage virtual machines (SVMs) to let SMB clients access files on your cluster.

- Each data SVM in the cluster can be bound to exactly one Active Directory domain.
- Data SVMs do not need to be bound to the same domain.
- Multiple SVMs can be bound to the same domain.

You must configure the SVMs and LIFs that you are using to serve data before you can create an SMB server. If your data network is not flat, you might also need to configure IPspaces, broadcast domains, and subnets. The *Network Management Guide* contains details.

Supported SMB versions and functionality

Server Message Block (SMB) is a remote file-sharing protocol used by Microsoft Windows clients and servers. In ONTAP 9, all SMB versions are supported; however, default SMB 1.0 support depends on your ONTAP version. You should verify that the ONTAP SMB server supports the clients and functionality required in your environment.

The latest information about which SMB clients and domain controllers ONTAP supports is available in the *Interoperability Matrix Tool*.

SMB 2.0 and later versions are enabled by default for ONTAP 9 SMB servers, and can be enabled or disabled as needed. The following table shows SMB 1.0 support and default configuration.

SMB 1.0 functionality:		In these ONTAP 9 releases:			
		9.0	9.1	9.2	9.3 and later
Is enabled by default		Yes	Yes	Yes	No
Can be enabled or disabled		No	Yes*9.1 P8 or later required.	Yes	Yes

 Default settings for SMB 1.0 and 2.0 connections to domain controllers also depend on the ONTAP version. More information is available in the `vserver cifs security modify` man page. For environments with existing CIFS servers running SMB 1.0, you should migrate to a later SMB version as soon as possible to prepare for security and compliance enhancements. Contact your NetApp representative for details.

The following table shows which SMB features are supported in each SMB version. Some SMB features are enabled by default and some require additional configuration.

This functionality:	Requires enablement:	Is supported in ONTAP 9 for these SMB versions:				
		1.0	2.0	2.1	3.0	3.1.1
Legacy SMB 1.0 functionality		X	X	X	X	X
Durable handles			X	X	X	X
Compounded operations			X	X	X	X
Asynchronous operations			X	X	X	X
Increased read and write buffer sizes			X	X	X	X
Increased scalability			X	X	X	X
SMB signing	X	X	X	X	X	X

This functionality:	Requires enablement:	Is supported in ONTAP 9 for these SMB versions:				
Alternate Data Stream (ADS) file format	X	X	X	X	X	X
Large MTU (enabled by default beginning with ONTAP 9.7)	X			X	X	X
Lease oplocks				X	X	X
Continuously available shares	X				X	X
Persistent handles					X	X
Witness					X	X
SMB encryption: AES-128-CCM	X				X	X
Scale out (required by CA shares)					X	X
Transparent failover					X	X
SMB Multichannel (beginning with ONTAP 9.4)	X				X	X
Preauthentication integrity						X
Cluster client failover v.2 (CCFv2)						X

This functionality:	Requires enablement:	Is supported in ONTAP 9 for these SMB versions:					
SMB encryption: AES-128-GCM (beginning with ONTAP 9.1)	X						X

Unsupported Windows features

Before you use CIFS in your network, you need to be aware of certain Windows features that ONTAP does not support.

ONTAP does not support the following Windows features:

- Encrypted File System (EFS)
- Logging of NT File System (NTFS) events in the change journal
- Microsoft File Replication Service (FRS)
- Microsoft Windows Indexing Service
- Remote storage through Hierarchical Storage Management (HSM)
- Quota management from Windows clients
- Windows quota semantics
- The LMHOSTS file
- NTFS native compression

Configure NIS or LDAP name services on the SVM

With SMB access, user mapping to a UNIX user is always performed, even when accessing data in an NTFS security-style volume. If you map Windows users to corresponding UNIX users whose information is stored in NIS or LDAP directory stores, or if you use LDAP for name mapping, you should configure these name services during SMB setup.

Before you begin

You must have customized your name services database configuration to match your name service infrastructure.

About this task

SVMs use the name services ns-switch databases to determine the order in which to look up the sources for a given name service database. The ns-switch source can be any combination of “files”, “nis”, or “ldap”. For the groups database, ONTAP attempts to get the group memberships from all configured sources and then uses the consolidated group membership information for access checks. If one of these sources is unavailable at the time of obtaining UNIX group information, ONTAP cannot get the complete UNIX credentials and subsequent access checks might fail. Therefore, you must always check that all ns-switch sources are configured for the group database in the ns-switch settings.

The default is to have the SMB server map all Windows users to the default UNIX user that is stored in the local `passwd` database. If you want to use the default configuration, configuring NIS or LDAP UNIX user and group name services or LDAP user mapping is optional for SMB access.

Steps

1. If UNIX user, group, and netgroup information is managed by NIS name services, configure NIS name services:
 - a. Determine the current ordering of name services by using the `vserver services name-service ns-switch show` command.

In this example, the three databases (`group`, `passwd`, and `netgroup`) that can use `nis` as a name service source are using only `files` as a source.

```
vserver services name-service ns-switch show -vserver vs1
```

Vserver	Database	Enabled	Source
vs1	hosts	true	dns, files
vs1	group	true	files
vs1	passwd	true	files
vs1	netgroup	true	files
vs1	namemap	true	files

You must add the `nis` source to the `group` and `passwd` databases, and optionally to the `netgroup` database.

- b. Adjust the name service ns-switch database ordering as desired by using the `vserver services name-service ns-switch modify` command.

For best performance, you should not add a name service to a name service database unless you plan on configuring that name service on the SVM.

If you modify the configuration for more than one name service database, you must run the command separately for each name service database that you want to modify.

In this example, `nis` and `files` are configured as sources for the `group` and `passwd` databases, in

that order. The rest of the name service databases are unchanged.

```
vserver services name-service ns-switch modify -vserver vs1 -database group  
-sources nis,files vserver services name-service ns-switch modify -vserver  
vs1 -database passwd -sources nis,files
```

- c. Verify that the ordering of name services is correct by using the vserver services name-service ns-switch show command.

```
vserver services name-service ns-switch show -vserver vs1
```

Vserver	Database	Enabled	Source Order
vs1	hosts	true	dns, files
vs1	group	true	nis, files
vs1	passwd	true	nis, files
vs1	netgroup	true	files
vs1	namemap	true	files

- d. Create the NIS name service configuration:

```
vserver services name-service nis-domain create -vserver vserver_name  
-domain NIS_domain_name -servers NIS_server_IPaddress,... -active true+
```

```
vserver services name-service nis-domain create -vserver vs1 -domain  
example.com -servers 10.0.0.60 -active true
```

Beginning with ONTAP 9.2, the field -nis-servers replaces the field -servers. This new field can take either a hostname or an IP address for the NIS server.

- e. Verify that the NIS name service is properly configured and active: vserver services name-service nis-domain show vserver vserver_name

```
vserver services name-service nis-domain show vserver vs1
```

Vserver	Domain	Active Server
vs1	example.com	true 10.0.0.60

2. If UNIX user, group, and netgroup information or name mapping is managed by LDAP name services, configure LDAP name services by using the information located [NFS management](#).

How ONTAP name service switch configuration works

ONTAP stores name service configuration information in a table that is the equivalent of the `/etc/nsswitch.conf` file on UNIX systems. You must understand the function of the table and how ONTAP uses it so that you can configure it appropriately for your environment.

The ONTAP name service switch table determines which name service sources ONTAP consults in which order to retrieve information for a certain type of name service information. ONTAP maintains a separate name service switch table for each SVM.

Database types

The table stores a separate name service list for each of the following database types:

Database type	Defines name service sources for...	Valid sources are...
hosts	Converting host names to IP addresses	files, dns
group	Looking up user group information	files, nis, ldap
passwd	Looking up user information	files, nis, ldap
netgroup	Looking up netgroup information	files, nis, ldap
namemap	Mapping user names	files, ldap

Source types

The sources specify which name service source to use for retrieving the appropriate information.

Specify source type...	To look up information in...	Managed by the command families...
files	Local source files	vserver services name-service unix-user vserver services name-service unix-group vserver services name-service netgroup vserver services name-service dns hosts
nis	External NIS servers as specified in the NIS domain configuration of the SVM	vserver services name-service nis-domain

Specify source type...	To look up information in...	Managed by the command families...
ldap	External LDAP servers as specified in the LDAP client configuration of the SVM	vserver services name-service ldap
dns	External DNS servers as specified in the DNS configuration of the SVM	vserver services name-service dns

Even if you plan to use NIS or LDAP for both data access and SVM administration authentication, you should still include `files` and configure local users as a fallback in case NIS or LDAP authentication fails.

Protocols used to access external sources

To access the servers for external sources, ONTAP uses the following protocols:

External name service source	Protocol used for access
NIS	UDP
DNS	UDP
LDAP	TCP

Example

The following example displays the name service switch configuration for the SVM `svm_1`:

```
cluster1::>*> vserver services name-service ns-switch show -vserver svm_1
                                         Source
Vserver          Database        Order
-----
svm_1            hosts          files,
                           dns
svm_1            group          files
svm_1            passwd         files
svm_1            netgroup       nis,
                           files
```

To look up user or group information, ONTAP consults only local sources `files`. If the query does not return any results, the lookup fails.

To look up netgroup information, ONTAP first consults external NIS servers. If the query does not return any results, the local netgroup file is checked next.

There are no name service entries for name mapping in the table for the SVM `svm_1`. Therefore, ONTAP consults only local source `files` by default.

Manage SMB servers

Modify SMB servers

You can move a SMB server from a workgroup to an Active Directory domain, from a workgroup to another workgroup, or from an Active Directory domain to a workgroup by using the `vserver cifs modify` command.

About this task

You can also modify other attributes of the SMB server, such as the SMB server name and administrative status. See the man page for details.

Choices

- Move the SMB server from a workgroup to an Active Directory domain:

- Set the administrative status of the SMB server to `down`.

```
Cluster1::>vserver cifs modify -vserver vs1 -status-admin down
```

- Move the SMB server from the workgroup to an Active Directory domain: `vserver cifs modify -vserver vserver_name -domain domain_name`

```
Cluster1::>vserver cifs modify -vserver vs1 -domain example.com
```

In order to create an Active Directory machine account for the SMB server, you must supply the name and password of a Windows account with sufficient privileges to add computers to the `ou=example` container within the `example.com` domain.

Beginning with ONTAP 9.7, your AD administrator can provide you with a URI to a keytab file as an alternative to providing you with a name and password to a privileged Windows account. When you receive the URI, include it in the `-keytab-uri` parameter with the `vserver cifs` commands.

- Move the SMB server from a workgroup to another workgroup:

- Set the administrative status of the SMB server to `down`.

```
Cluster1::>vserver cifs modify -vserver vs1 -status-admin down
```

- Modify the workgroup for the SMB server: `vserver cifs modify -vserver vserver_name -workgroup new_workgroup_name`

```
Cluster1::>vserver cifs modify -vserver vs1 -workgroup workgroup2
```

- Move the SMB server from an Active Directory domain to a workgroup:

- Set the administrative status of the SMB server to `down`.

```
Cluster1::>vserver cifs modify -vserver vs1 -status-admin down
```

- b. Move the SMB server from the Active Directory domain to a workgroup: `vserver cifs modify -vserver vserver_name -workgroup workgroup_name`

```
cluster1::> vserver cifs modify -vserver vs1 -workgroup workgroup1
```

To enter workgroup mode, all domain-based features must be disabled and their configuration removed automatically by the system, including continuously-available shares, shadow copies, and AES. However, domain-configured share ACLs such as "EXAMPLE.COM\userName" will not work properly, but cannot be removed by ONTAP. Remove these share ACLs as soon as possible using external tools after the command completes. If AES is enabled, you may be asked to supply the name and password of a Windows account with sufficient privileges to disable it in the "EXAMPLE.COM" domain.

- Modify other attributes by using the appropriate parameter of the `vserver cifs modify` command.

Use options to customize CIFS servers

Available SMB server options

It is useful to know what options are available when considering how to customize the SMB server. Although some options are for general use on the SMB server, several are used to enable and configure specific SMB functionality. SMB server options are controlled with the `vserver cifs options modify` option.

The following list specifies the SMB server options that are available at the admin privilege level:

- **Configuring the SMB session timeout value**

Configuring this option enables you to specify the number of seconds of idle time before an SMB session is disconnected. An idle session is a session in which a user does not have any files or directories opened on the client. The default value is 900 seconds.

- **Configuring the default UNIX user**

Configuring this option enables you to specify the default UNIX user that the SMB server uses. ONTAP automatically creates a default user named "pcuser" (with a UID of 65534), creates a group named "pcuser" (with a GID of 65534), and adds the default user to the "pcuser" group. When you create a SMB server, ONTAP automatically configures "pcuser" as the default UNIX user.

- **Configuring the guest UNIX user**

Configuring this option enables you to specify the name of a UNIX user to which users who log in from untrusted domains are mapped, which allows a user from an untrusted domain to connect to the SMB server. By default, this option is not configured (there is no default value); therefore, the default is to not allow users from untrusted domains to connect to the SMB server.

- **Enabling or disabling read grant execution for mode bits**

Enabling or disabling this option enables you to specify whether to allow SMB clients to run executable files with UNIX mode bits to which they have read access, even when the UNIX executable bit is not set. This option is disabled by default.

- **Enabling or disabling the ability to delete read-only files from NFS clients**

Enabling or disabling this option determines whether to allow NFS clients to delete files or folders with the read-only attribute set. NTFS delete semantics does not allow the deletion of a file or folder when the read-only attribute is set. UNIX delete semantics ignores the read-only bit, using the parent directory permissions instead to determine whether a file or folder can be deleted. The default setting is disabled, which results in NTFS delete semantics.

- **Configuring Windows Internet Name Service server addresses**

Configuring this option enables you to specify a list of Windows Internet Name Service (WINS) server addresses as a comma-delimited list. You must specify IPv4 addresses. IPv6 addresses are not supported. There is no default value.

The following list specifies the SMB server options that are available at the advanced privilege level:

- **Granting UNIX group permissions to CIFS users**

Configuring this option determines whether the incoming CIFS user who is not the owner of the file can be granted the group permission. If the CIFS user is not the owner of the UNIX security-style file and this parameter is set to `true`, then the group permission is granted for the file. If the CIFS user is not the owner of the UNIX security-style file and this parameter is set to `false`, then the normal UNIX rules are applicable to grant the file permission. This parameter is applicable to UNIX security-style files that have permission set as `mode bits` and is not applicable to files with the NTFS or NFSv4 security mode. The default setting is `false`.

- **Enabling or disabling SMB 1.0**

SMB 1.0 is disabled by default on an SVM for which a SMB server is created in ONTAP 9.3.

Beginning ONTAP 9.3, SMB 1.0 is disabled by default for new SMB servers created in ONTAP 9.3. You should migrate to a later SMB version as soon as possible to prepare for security and compliance enhancements. Contact your NetApp representative for details.

- **Enabling or disabling SMB 2.x**

SMB 2.0 is the minimum SMB version that supports LIF failover. If you disable SMB 2.x, ONTAP also automatically disables SMB 3.0.

SMB 2.0 is supported only on SVMs. The option is enabled by default on SVMs

- **Enabling or disabling SMB 3.0**

SMB 3.0 is the minimum SMB version that supports continuously available shares. Windows Server 2012 and Windows 8 are the minimum Windows versions that support SMB 3.0.

SMB 3.0 is supported only on SVMs. The option is enabled by default on SVMs

- **Enabling or disabling SMB 3.1**

Windows 10 is the only Windows version that supports SMB 3.1.

SMB 3.1 is supported only on SVMs. The option is enabled by default on SVMs

- **Enabling or disabling ODX copy offload**

ODX copy offload is used automatically by Windows clients that support it. This option is enabled by default.

- **Enabling or disabling the direct-copy mechanism for ODX copy offload**

The direct-copy mechanism increases the performance of the copy offload operation when Windows clients try to open the source file of a copy in a mode that prevents the file being changed while the copy is in progress. By default, the direct copy mechanism is enabled.

- **Enabling or disabling automatic node referrals**

With automatic node referrals, the SMB server automatically refers clients to a data LIF local to the node that hosts the data accessed through the requested share.

- **Enabling or disabling export policies for SMB**

This option is disabled by default.

- **Enabling or disabling using junction points as reparse points**

If this option is enabled, the SMB server exposes junction points to SMB clients as reparse points. This option is valid only for SMB 2.x or SMB 3.0 connections. This option is enabled by default.

This option is supported only on SVMs. The option is enabled by default on SVMs

- **Configuring the number of maximum simultaneous operations per TCP connection**

The default value is 255.

- **Enabling or disabling local Windows users and groups functionality**

This option is enabled by default.

- **Enabling or disabling local Windows users authentication**

This option is enabled by default.

- **Enabling or disabling VSS shadow copy functionality**

ONTAP uses the shadow copy functionality to perform remote backups of data stored using the Hyper-V over SMB solution.

This option is supported only on SVMs, and only for Hyper-V over SMB configurations. The option is enabled by default on SVMs

- **Configuring the shadow copy directory depth**

Configuring this option enables you to define the maximum depth of directories on which to create shadow

copies when using the shadow copy functionality.

This option is supported only on SVMs, and only for Hyper-V over SMB configurations. The option is enabled by default on SVMs

- **Enabling or disabling multidomain search capabilities for name mapping**

If enabled, when a UNIX user is mapped to a Windows domain user by using a wildcard (*) in the domain portion of the Windows user name (for example, *\joe), ONTAP searches for the specified user in all of the domains with bidirectional trusts to the home domain. The home domain is the domain that contains the SMB server's computer account.

As an alternative to searching all of the bidirectionally trusted domains, you can configure a list of preferred trusted domains. If this option is enabled and a preferred list is configured, the preferred list is used to perform multidomain name mapping searches.

The default is to enable multidomain name mapping searches.

- **Configuring the file system sector size**

Configuring this option enables you to configure the file system sector size in bytes that ONTAP reports to SMB clients. There are two valid values for this option: 4096 and 512. The default value is 4096. You might need to set this value to 512 if the Windows application supports only a sector size of 512 bytes.

- **Enabling or disabling Dynamic Access Control**

Enabling this option enables you to secure objects on the SMB server by using Dynamic Access Control (DAC), including using auditing to stage central access policies and using Group Policy Objects to implement central access policies. The option is disabled by default.

This option is supported only on SVMs.

- **Setting the access restrictions for non-authenticated sessions (restrict anonymous)**

Setting this option determines what the access restrictions are for non-authenticated sessions. The restrictions are applied to anonymous users. By default, there are no access restrictions for anonymous users.

- **Enabling or disabling the presentation of NTFS ACLs on volumes with UNIX effective security (UNIX security-style volumes or mixed security-style volumes with UNIX effective security)**

Enabling or disabling this option determines how file security on files and folders with UNIX security is presented to SMB clients. If enabled, ONTAP presents files and folders in volumes with UNIX security to SMB clients as having NTFS file security with NTFS ACLs. If disabled, ONTAP presents volumes with UNIX security as FAT volumes, with no file security. By default, volumes are presented as having NTFS file security with NTFS ACLs.

- **Enabling or disabling the SMB fake open functionality**

Enabling this functionality improves SMB 2.x and SMB 3.0 performance by optimizing how ONTAP makes open and close requests when querying for attribute information on files and directories. By default, the SMB fake open functionality is enabled. This option is useful only for connections that are made with SMB 2.x or later.

- **Enabling or disabling the UNIX extensions**

Enabling this option enables UNIX extensions on a SMB server. UNIX extensions allow POSIX/UNIX style security to be displayed through the SMB protocol. By default this option is disabled.

If you have UNIX-based SMB clients, such as Mac OSX clients, in your environment, you should enable UNIX extensions. Enabling UNIX extensions allows the SMB server to transmit POSIX/UNIX security information over SMB to the UNIX-based client, which then translates the security information into POSIX/UNIX security.

- **Enabling or disabling support for short name searches**

Enabling this option allows the SMB server to perform searches on short names. A search query with this option enabled tries to match 8.3 file names along with long file names. The default value for this parameter is `false`.

- **Enabling or disabling support for automatic advertisement of DFS capabilities**

Enabling or disabling this option determines whether SMB servers automatically advertise DFS capabilities to SMB 2.x and SMB 3.0 clients that connect to shares. ONTAP uses DFS referrals in the implementation of symbolic links for SMB access. If enabled, the SMB server always advertises DFS capabilities regardless of whether symbolic link access is enabled. If disabled, the SMB server advertises DFS capabilities only when the clients connect to shares where symbolic link access is enabled.

- **Configuring the maximum number of SMB credits**

Beginning with ONTAP 9.4, configuring the `-max-credits` option allows you to limit the number of credits to be granted on an SMB connection when clients and server are running SMB version 2 or later. The default value is 128.

- **Enabling or disabling support for SMB Multichannel**

Enabling the `-is-multichannel-enabled` option in ONTAP 9.4 and later releases allows the SMB server to establish multiple connections for a single SMB session when appropriate NICs are deployed on the cluster and its clients. Doing so improves throughput and fault tolerance. The default value for this parameter is `false`.

When SMB Multichannel is enabled, you can also specify the following parameters:

- The maximum number of connections allowed per Multichannel session. The default value for this parameter is 32.
- The maximum number of network interfaces advertised per Multichannel session. The default value for this parameter is 256.

Configuring CIFS server options

You can configure CIFS server options at any time after you have created a CIFS server on a storage virtual machine (SVM).

Step

1. Perform the desired action:

If you want to configure CIFS server options...	Enter the command...
At admin-privilege level	<code>vserver cifs options modify -vserver vserver_name options</code>
At advanced-privilege level	<ul style="list-style-type: none"> a. <code>set -privilege advanced</code> b. <code>vserver cifs options modify -vserver vserver_name options</code> c. <code>set -privilege admin</code>

For more information about configuring CIFS server options, see the man page for the `vserver cifs options modify` command.

Configure the grant UNIX group permission to CIFS users

You can configure this option to grant group permissions to access files or directories even if the incoming CIFS user is not the owner of the file.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Configure the grant UNIX group permission as appropriate:

If you want to	Enter the command
Enable the access to the files or directories to get group permissions even if the user is not the owner of the file	<code>vserver cifs options modify -grant-unix-group-perms-to-others true</code>
Disable the access to the files or directories to get group permissions even if the user is not the owner of the file	<code>vserver cifs options modify -grant-unix-group-perms-to-others false</code>

3. Verify that the option is set to the desired value: `vserver cifs options show -fields grant-unix-group-perms-to-others`
4. Return to the admin privilege level: `set -privilege admin`

Configure access restrictions for anonymous users

By default, an anonymous, unauthenticated user (also known as the *null user*) can access certain information on the network. You can use a SMB server option to configure access restrictions for the anonymous user.

About this task

The `-restrict-anonymous` SMB server option corresponds to the `RestrictAnonymous` registry entry in Windows.

Anonymous users can list or enumerate certain types of system information from Windows hosts on the

network, including user names and details, account policies, and share names. You can control access for the anonymous user by specifying one of three access restriction settings:

Value	Description
no-restriction (default)	Specifies no access restrictions for anonymous users.
no-enumeration	Specifies that only enumeration is restricted for anonymous users.
no-access	Specifies that access is restricted for anonymous users.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Configure the restrict anonymous setting: `vserver cifs options modify -vserver vserver_name -restrict-anonymous {no-restriction|no-enumeration|no-access}`
3. Verify that the option is set to the desired value: `vserver cifs options show -vserver vserver_name`
4. Return to the admin privilege level: `set -privilege admin`

Manage how file security is presented to SMB clients for UNIX security-style data

Manage how file security is presented to SMB clients for UNIX security-style data overview

You can choose how you want to present file security to SMB clients for UNIX security-style data by enabling or disabling the presentation of NTFS ACLs to SMB clients. There are advantages with each setting, which you should understand to choose the setting best suited for your business requirements.

By default, ONTAP presents UNIX permissions on UNIX security-style volumes to SMB clients as NTFS ACLs. There are scenarios where this is desirable, including the following:

- You want to view and edit UNIX permissions by using the **Security** tab in the Windows Properties box.

You cannot modify permissions from a Windows client if the operation is not permitted by the UNIX system. For example, you cannot change the ownership of a file you do not own, because the UNIX system does not permit this operation. This restriction prevents SMB clients from bypassing UNIX permissions set on the files and folders.

- Users are editing and saving files on the UNIX security-style volume by using certain Windows applications, for example Microsoft Office, where ONTAP must preserve UNIX permissions during save operations.
- There are certain Windows applications in your environment that expect to read NTFS ACLs on files they use.

Under certain circumstances, you might want to disable the presentation of UNIX permissions as NTFS ACLs. If this functionality is disabled, ONTAP presents UNIX security-style volumes as FAT volumes to SMB clients. There are specific reasons why you might want to present UNIX security-style volumes as FAT volumes to SMB clients:

- You only change UNIX permissions by using mounts on UNIX clients.

The Security tab is not available when a UNIX security-style volume is mapped on an SMB client. The mapped drive appears to be formatted with the FAT file system, which has no file permissions.

- You are using applications over SMB that set NTFS ACLs on accessed files and folders, which can fail if the data resides on UNIX security-style volumes.

If ONTAP reports the volume as FAT, the application does not try to change an ACL.

[Configuring security styles on FlexVol volumes](#)

[Configuring security styles on qtrees](#)

Enable or disable the presentation of NTFS ACLs for UNIX security-style data

You can enable or disable the presentation of NTFS ACLs to SMB clients for UNIX security-style data (UNIX security-style volumes and mixed security-style volumes with UNIX effective security).

About this task

If you enable this option, ONTAP presents files and folders on volumes with effective UNIX security style to SMB clients as having NTFS ACLs. If you disable this option, the volumes are presented as FAT volumes to SMB clients. The default is to present NTFS ACLs to SMB clients.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Configure the UNIX NTFS ACL option setting: `vserver cifs options modify -vserver vserver_name -is-unix-nt-acl-enabled {true|false}`
3. Verify that the option is set to the desired value: `vserver cifs options show -vserver vserver_name`
4. Return to the admin privilege level: `set -privilege admin`

How ONTAP preserves UNIX permissions

When files in a FlexVol volume that currently have UNIX permissions are edited and saved by Windows applications, ONTAP can preserve the UNIX permissions.

When applications on Windows clients edit and save files, they read the security properties of the file, create a new temporary file, apply those properties to the temporary file, and then give the temporary file the original file name.

When Windows clients perform a query for the security properties, they receive a constructed ACL that exactly represents the UNIX permissions. The sole purpose of this constructed ACL is to preserve the file's UNIX permissions as files are updated by Windows applications to ensure that the resulting files have the same

UNIX permissions. ONTAP does not set any NTFS ACLs using the constructed ACL.

Manage UNIX permissions using the Windows Security tab

If you want to manipulate UNIX permissions of files or folders in mixed security-style volumes or qtrees on SVMs, you can use the Security tab on Windows clients. Alternatively, you can use applications that can query and set Windows ACLs.

- Modifying UNIX permissions

You can use the Windows Security tab to view and change UNIX permissions for a mixed security-style volume or qtree. If you use the main Windows Security tab to change UNIX permissions, you must first remove the existing ACE you want to edit (this sets the mode bits to 0) before you make your changes. Alternatively, you can use the Advanced editor to change permissions.

If mode permissions are used, you can directly change the mode permissions for the listed UID, GID, and others (everyone else with an account on the computer). For example, if the displayed UID has r-x permissions, you can change the UID permissions to rwx.

- Changing UNIX permissions to NTFS permissions

You can use the Windows Security tab to replace UNIX security objects with Windows security objects on a mixed security-style volume or qtree where the files and folders have a UNIX effective security style.

You must first remove all listed UNIX permission entries before you can replace them with the desired Windows User and Group objects. You can then configure NTFS-based ACLs on the Windows User and Group objects. By removing all UNIX security objects and adding only Windows Users and Groups to a file or folder in a mixed security-style volume or qtree, you change the effective security style on the file or folder from UNIX to NTFS.

When changing permissions on a folder, the default Windows behavior is to propagate these changes to all subfolders and files. Therefore, you must change the propagation choice to the desired setting if you do not want to propagate a change in security style to all child folders, subfolders, and files.

Manage SMB server security settings

How ONTAP handles SMB client authentication

Before users can create SMB connections to access data contained on the SVM, they must be authenticated by the domain to which the SMB server belongs. The SMB server supports two authentication methods, Kerberos and NTLM (NTLMv1 or NTLMv2). Kerberos is the default method used to authenticate domain users.

Kerberos authentication

ONTAP supports Kerberos authentication when creating authenticated SMB sessions.

Kerberos is the primary authentication service for Active Directory. The Kerberos server, or Kerberos Key Distribution Center (KDC) service, stores and retrieves information about security principles in the Active Directory. Unlike the NTLM model, Active Directory clients who want to establish a session with another computer, such the SMB server, contact a KDC directly to obtain their session credentials.

NTLM authentication

NTLM client authentication is done using a challenge response protocol based on shared knowledge of a user-specific secret based on a password.

If a user creates an SMB connection using a local Windows user account, authentication is done locally by the SMB server using NTLMv2.

Guidelines for SMB server security settings in an SVM disaster recovery configuration

Before creating an SVM that is configured as a disaster recovery destination where the identity is not preserved (the `-identity-preserve` option is set to `false` in the SnapMirror configuration), you should know about how SMB server security settings are managed on the destination SVM.

- Non-default SMB server security settings are not replicated to the destination.

When you create a SMB server on the destination SVM, all SMB server security settings are set to default values. When the SVM disaster recovery destination is initialized, updated, or resynced, the SMB server security settings on the source are not replicated to the destination.

- You must manually configure non-default SMB server security settings.

If you have non-default SMB server security settings configured on the source SVM, you must manually configure these same settings on the destination SVM after the destination becomes read-write (after the SnapMirror relationship is broken).

Display information about SMB server security settings

You can display information about SMB server security settings on your storage virtual machines (SVMs). You can use this information to verify that the security settings are correct.

About this task

A displayed security setting can be the default value for that object or a non-default value that is configured either by using the ONTAP CLI or by using Active Directory group policy objects (GPOs).

Do not use the `vserver cifs security show` command for SMB servers in workgroup mode, because some of the options are not valid.

Step

1. Perform one of the following actions:

If you want display information about...	Enter the command...
All security settings on a specified SVM	<code>vserver cifs security show -vserver <i>vserver_name</i></code>

If you want display information about...	Enter the command...
A specific security setting or settings on the SVM	vserver cifs security show -vserver _vserver_name_-fields [fieldname,...] You can enter -fields ? to determine what fields you can use.

Example

The following example shows all security settings for SVM vs1:

```
cluster1::> vserver cifs security show -vserver vs1

Vserver: vs1

          Kerberos Clock Skew:      5 minutes
          Kerberos Ticket Age:    10 hours
          Kerberos Renewal Age:   7 days
          Kerberos KDC Timeout:  3 seconds
          Is Signing Required:  false
          Is Password Complexity Required: true
          Use start_tls For AD LDAP connection: false
          Is AES Encryption Enabled: false
          LM Compatibility Level: lm-ntlm-ntlmv2-krb
          Is SMB Encryption Required: false
          Client Session Security: none
          SMB1 Enabled for DC Connections: false
          SMB2 Enabled for DC Connections: system-default
LDAP Referral Enabled For AD LDAP connections: false
          Use LDAPS for AD LDAP connection: false
Encryption is required for DC Connections: false
AES session key enabled for NetLogon channel: false
Try Channel Binding For AD LDAP Connections: false
```

Note that the settings displayed depend on the running ONTAP version.

The following example shows the Kerberos clock skew for SVM vs1:

```
cluster1::> vserver cifs security show -vserver vs1 -fields kerberos-
clock-skew

          vserver kerberos-clock-skew
          -----
vs1      5
```

Related information

Displaying information about GPO configurations

Enable or disable required password complexity for local SMB users

Required password complexity provides enhanced security for local SMB users on your storage virtual machines (SVMs). The required password complexity feature is enabled by default. You can disable it and reenable it at any time.

Before you begin

Local users, local groups, and local user authentication must be enabled on the CIFS server.

About this task

You must not use the `vserver cifs security modify` command for a CIFS server in workgroup mode because some of the options are not valid.

Steps

1. Perform one of the following actions:

If you want required password complexity for local SMB users to be...	Enter the command...
Enabled	<code>vserver cifs security modify -vserver vserver_name -is-password-complexity-required true</code>
Disabled	<code>vserver cifs security modify -vserver vserver_name -is-password-complexity-required false</code>

2. Verify the security setting for required password complexity: `vserver cifs security show -vserver vserver_name`

Example

The following example shows that required password complexity is enabled for local SMB users for SVM vs1:

```
cluster1::> vserver cifs security modify -vserver vs1 -is-password-complexity-required true

cluster1::> vserver cifs security show -vserver vs1 -fields is-password-complexity-required
vserver is-password-complexity-required
-----
vs1      true
```

Changing local user account passwords

Modify the CIFS server Kerberos security settings

You can modify certain CIFS server Kerberos security settings, including the maximum allowed Kerberos clock slew time, the Kerberos ticket lifetime, and the maximum number of ticket renewal days.

About this task

Modifying CIFS server Kerberos settings by using the `vserver cifs security modify` command modifies the settings only on the single storage virtual machine (SVM) that you specify with the `-vserver` parameter. You can centrally manage Kerberos security settings for all SVMs on the cluster belonging to the same Active Directory domain by using Active Directory group policy objects (GPOs).

Steps

1. Perform one or more of the following actions:

If you want to...	Enter...
Specify the maximum allowed Kerberos clock skew time in minutes	<code>vserver cifs security modify -vserver vserver_name -kerberos-clock-skew integer_in_minutes</code> The default setting is 5 minutes.
Specify the Kerberos ticket lifetime in hours	<code>vserver cifs security modify -vserver vserver_name -kerberos-ticket-age integer_in_hours</code> The default setting is 10 hours.
Specify the maximum number of ticket renewal days	<code>vserver cifs security modify -vserver vserver_name -kerberos-renew-age integer_in_days</code> The default setting is 7 days.
Specify the timeout for sockets on KDCs after which all KDCs are marked as unreachable	<code>vserver cifs security modify -vserver vserver_name -kerberos-kdc-timeout integer_in_seconds</code> The default setting is 3 seconds.

2. Verify the Kerberos security settings: `vserver cifs security show -vserver vserver_name`

Example

The following example makes the following changes to Kerberos security: Kerberos Clock Skew is set to 3 minutes and Kerberos Ticket Age is set to 8 hours for SVM vs1:

```

cluster1::> vserver cifs security modify -vserver vs1 -kerberos-clock-skew
3 -kerberos-ticket-age 8

cluster1::> vserver cifs security show -vserver vs1

Vserver: vs1

          Kerberos Clock Skew:            3 minutes
          Kerberos Ticket Age:           8 hours
          Kerberos Renewal Age:         7 days
          Kerberos KDC Timeout:        3 seconds
          Is Signing Required:         false
          Is Password Complexity Required: true
          Use start_tls For AD LDAP connection: false
          Is AES Encryption Enabled:   false

[Applying Group Policy Objects to CIFS servers](#)

Set the SMB server minimum authentication security level

You can set the SMB server minimum security level, also known as the *LMCompatibilityLevel*, on your SMB server to meet your business security requirements for SMB client access. The minimum security level is the minimum level of the security tokens that the SMB server accepts from SMB clients.

About this task

- SMB servers in workgroup mode support only NTLM authentication. Kerberos authentication is not supported.
- LMCompatibilityLevel applies only to SMB client authentication, not admin authentication.

You can set the minimum authentication security level to one of four supported security levels.

Value	Description
lm-ntlm-ntlmv2-krb (default)	The storage virtual machine (SVM) accepts LM, NTLM, NTLMv2, and Kerberos authentication security.

Value	Description
ntlm-ntlmv2-krb	The SVM accepts NTLM, NTLMv2, and Kerberos authentication security. The SVM denies LM authentication.
ntlmv2-krb	The SVM accepts NTLMv2 and Kerberos authentication security. The SVM denies LM and NTLM authentication.
krb	The SVM accepts Kerberos authentication security only. The SVM denies LM, NTLM, and NTLMv2 authentication.

Steps

1. Set the minimum authentication security level: `vserver cifs security modify -vserver vserver_name -lm-compatibility-level {lm-ntlm-ntlmv2-krb|ntlm-ntlmv2-krb|ntlmv2-krb|krb}`
2. Verify that the authentication security level is set to the desired level: `vserver cifs security show -vserver vserver_name`

Related information

[Enabling or disabling AES encryption for Kerberos-based communication](#)

Configure strong security for Kerberos-based communication by using AES encryption

For strongest security with Kerberos-based communication, you can enable AES-256 and AES-128 encryption on the SMB server. By default, when you create a SMB server on the SVM, AES encryption is disabled. You must enable it to take advantage of the strong security provided by Advanced Encryption Standard (AES) encryption.

Kerberos-related communication for SMB is used during SMB server creation on the SVM, as well as during the SMB session setup phase. The SMB server supports the following encryption types for Kerberos communication:

- RC4-HMAC
- DES
- AES 128
- AES 256

If you want to use the highest security encryption type for Kerberos communication, you should enable AES encryption for Kerberos communication on the SVM.

 Intel AES New Instructions (Intel AES NI) is available in SMB 3.0, improving on the AES algorithm and accelerating data encryption with supported processor families. Beginning with SMB 3.1.1, AES-128-GCM replaces AES-128-CCM as the hash algorithm used by SMB encryption.

When the SMB server is created, the domain controller creates a computer machine account in Active

Directory. At this time, the KDC becomes aware of the encryption capabilities of the particular machine account. Subsequently, a particular encryption type is selected for encrypting the service ticket that the client presents to the server during authentication.

Related information

[Modifying the CIFS server Kerberos security settings](#)

Enable or disable AES encryption for Kerberos-based communication

To take advantage of the strongest security with Kerberos-based communication, you can enable AES-256 and AES-128 encryption on the SMB server. If you do not want the SMB server to select the AES encryption types for Kerberos-based communication with the Active Directory (AD) KDC, you can disable AES encryption. By default, AES encryption is disabled.

About this task

To enhance security, the storage virtual machine (SVM) changes its machine account password in the AD each time the AES security option is modified. Changing the password might require administrative AD credentials for the organizational unit (OU) that contains the machine account.

If an SVM is configured as a disaster recovery destination where the identity is not preserved (the `-identity-preserve` option is set to `false` in the SnapMirror configuration), the non-default SMB server security settings are not replicated to the destination. If you have enabled AES encryption on the source SVM, you must manually enable it on the destination SVM after the destination becomes read-write (after the SnapMirror relationship is broken).

Steps

1. Perform one of the following actions:

If you want the AES encryption types for Kerberos communication to be...	Enter the command...
Enabled	<code>vserver cifs security modify -vserver vserver_name -is-aes-encryption-enabled true</code>
Disabled	<code>vserver cifs security modify -vserver vserver_name -is-aes-encryption-enabled false</code>

2. Verify that AES encryption is enabled or disabled as desired: `vserver cifs security show -vserver vserver_name -fields is-aes-encryption-enabled`

The `is-aes-encryption-enabled` field displays `true` if AES encryption is enabled and `false` if it is disabled.

Example

The following example enables the AES encryption types for the CIFS server on SVM vs1:

```
cluster1::> vserver cifs security modify -vserver vs1 -is-aes-encryption  
-enabled true  
  
cluster1::> vserver cifs security show -vserver vs1 -fields is-aes-  
encryption-enabled  
vserver is-aes-encryption-enabled  
-----  
vs1 true
```

The following example enables the AES encryption types for the SMB server on SVM vs2. The administrator is prompted to enter the administrative AD credentials for the OU containing the SMB server.

```
cluster1::> vserver cifs security modify -vserver vs2 -is-aes-encryption  
-enabled true
```

Info: In order to enable SMB AES encryption, the password for the SMB server machine account must be reset. Enter the username and password for the SMB domain "EXAMPLE.COM".

Enter your user ID: administrator

Enter your password:

```
cluster1::> vserver cifs security show -vserver vs2 -fields is-aes-  
encryption-enabled  
vserver is-aes-encryption-enabled  
-----  
vs2 true
```

Use SMB signing to enhance network security

Use SMB signing to enhance network security overview

SMB signing helps to ensure that network traffic between the SMB server and the client is not compromised; it does this by preventing replay attacks. By default, ONTAP supports SMB signing when requested by the client. Optionally, the storage administrator can configure the SMB server to require SMB signing.

How SMB signing policies affect communication with a CIFS server

In addition to the CIFS server SMB signing security settings, two SMB signing policies on Windows clients control the digital signing of communications between clients and the CIFS server. You can configure the setting that meets your business requirements.

Client SMB policies are controlled through Windows local security policy settings, which are configured by using the Microsoft Management Console (MMC) or Active Directory GPOs. For more information about client SMB signing and security issues, see the Microsoft Windows documentation.

Here are descriptions of the two SMB signing policies on Microsoft clients:

- Microsoft network client: Digitally sign communications (if server agrees)

This setting controls whether the client's SMB signing capability is enabled. It is enabled by default. When this setting is disabled on the client, the client communications with the CIFS server depends on the SMB signing setting on the CIFS server.

- Microsoft network client: Digitally sign communications (always)

This setting controls whether the client requires SMB signing to communicate with a server. It is disabled by default. When this setting is disabled on the client, SMB signing behavior is based on the policy setting for Microsoft network client: Digitally sign communications (if server agrees) and the setting on the CIFS server.

If your environment includes Windows clients configured to require SMB signing, you must enable SMB signing on the CIFS server. If you do not, the CIFS server cannot serve data to these systems.

The effective results of client and CIFS server SMB signing settings depends on whether the SMB sessions uses SMB 1.0 or SMB 2.x and later.

The following table summarizes the effective SMB signing behavior if the session uses SMB 1.0:

Client	ONTAP—signing not required	ONTAP—signing required
Signing disabled and not required	Not signed	Signed
Signing enabled and not required	Not signed	Signed
Signing disabled and required	Signed	Signed
Signing enabled and required	Signed	Signed

Older Windows SMB 1 clients and some non-Windows SMB 1 clients might fail to connect if signing is disabled on the client but required on the CIFS server.

The following table summarizes the effective SMB signing behavior if the session uses SMB 2.x or SMB 3.0:

For SMB 2.x and SMB 3.0 clients, SMB signing is always enabled. It cannot be disabled.

Client	ONTAP—signing not required	ONTAP—signing required
Signing not required	Not signed	Signed

Client	ONTAP—signing not required	ONTAP—signing required
Signing required	Signed	Signed

The following table summarizes the default Microsoft client and server SMB signing behavior:

Protocol	Hash algorithm	Can enable/disable	Can require/not require	Client default	Server default	DC default
SMB 1.0	MD5	Yes	Yes	Enabled (not required)	Disabled (not required)	Required
SMB 2.x	HMAC SHA-256	No	Yes	Not required	Not required	Required
SMB 3.0	AES-CMAC.	No	Yes	Not required	Not required	Required

 Microsoft no longer recommends using Digitally sign communications (if client agrees) or Digitally sign communications (if server agrees) Group Policy settings. Microsoft also no longer recommends using the `EnableSecuritySignature` registry settings. These options only affect the SMB 1 behavior and can be replaced by the Digitally sign communications (always) Group Policy setting or the `RequireSecuritySignature` registry setting. You can also get more information from the Microsoft Blog.<http://blogs.technet.com/b/josebda/archive/2010/12/01/the-basics-of-smb-signing-covering-both-smb1-and-smb2.aspx>[The Basics of SMB Signing (covering both SMB1 and SMB2)]

Performance impact of SMB signing

When SMB sessions use SMB signing, all SMB communications to and from Windows clients experience a performance impact, which affects both the clients and the server (that is, the nodes on the cluster running the SVM containing the SMB server).

The performance impact shows as increased CPU usage on both the clients and the server, although the amount of network traffic does not change.

The extent of the performance impact depends on the version of ONTAP 9 you are running. Beginning with ONTAP 9.7, a new encryption off-load algorithm can enable better performance in signed SMB traffic. SMB signing offload is enabled by default when SMB signing is enabled.

Enhanced SMB signing performance requires AES-NI offload capability. See the Hardware Universe (HWU) to verify that AES-NI offload is supported for your platform.

Further performance improvements are also possible if you are able to use SMB version 3.11 (supported with Windows 10 and Windows Server 2016), which supports the much faster GCM algorithm.

Depending on your network, ONTAP 9 version, SMB version, and SVM implementation, the performance impact of SMB signing can vary widely; you can verify it only through testing in your network environment.

Most Windows clients negotiate SMB signing by default if it is enabled on the server. If you require SMB

protection for some of your Windows clients, and if SMB signing is causing performance issues, you can disable SMB signing on any of your Windows clients that do not require protection against replay attacks. For information about disabling SMB signing on Windows clients, see the Microsoft Windows documentation.

Recommendations for configuring SMB signing

You can configure SMB signing behavior between SMB clients and the CIFS server to meet your security requirements. The settings you choose when configuring SMB signing on your CIFS server are dependent on what your security requirements are.

You can configure SMB signing on either the client or the CIFS server. Consider the following recommendations when configuring SMB signing:

If...	Recommendation...
You want to increase the security of the communication between the client and the server	Make SMB signing required at the client by enabling the Require Option (Sign always) security setting on the client.
You want all SMB traffic to a certain storage virtual machine (SVM) signed	Make SMB signing required on the CIFS server by configuring the security settings to require SMB signing.

See Microsoft documentation for more information on configuring Windows client security settings.

Guidelines for SMB signing when multiple data LIFs are configured

If you enable or disable required SMB signing on the SMB server, you should be aware of the guidelines for multiple data LIFs configurations for an SVM.

When you configure a SMB server, there might be multiple data LIFs configured. If so, the DNS server contains multiple A record entries for the CIFS server, all using the same SMB server host name, but each with a unique IP address. For example, a SMB server that has two data LIFs configured might have the following DNS A record entries:

```
10.1.1.128 A VS1.IEPUB.LOCAL VS1
10.1.1.129 A VS1.IEPUB.LOCAL VS1
```

The normal behavior is that upon changing the required SMB signing setting, only new connections from clients are affected by the change in the SMB signing setting. However, there is an exception to this behavior. There is a case where a client has an existing connection to a share, and the client creates a new connection to the same share after the setting is changed, while maintaining the original connection. In this case, both the new and the existing SMB connection adopt the new SMB signing requirements.

Consider the following example:

1. Client1 connects to a share without required SMB signing using the path O:\.
2. The storage administrator modifies the SMB server configuration to require SMB signing.
3. Client1 connects to the same share with required SMB signing using the path S:\ (while maintaining the

connection using the path `o:\`).

4. The result is that SMB signing is used when accessing data over both the `o:\` and `s:\` drives.

Enable or disable required SMB signing for incoming SMB traffic

You can enforce the requirement for clients to sign SMB messages by enabling required SMB signing. If enabled, ONTAP accepts SMB messages only if they have valid signatures. If you want to permit SMB signing, but not require it, you can disable required SMB signing.

About this task

By default, required SMB signing is disabled. You can enable or disable required SMB signing at any time.

SMB signing is not disabled by default under the following circumstances:

1. Required SMB signing is enabled, and the cluster is reverted to a version of ONTAP that does not support SMB signing.
2. The cluster is subsequently upgraded to a version of ONTAP that supports SMB signing.

 Under these circumstances, the SMB signing configuration that was originally configured on a supported version of ONTAP is retained through reversion and subsequent upgrade.

When you set up a storage virtual machine (SVM) disaster recovery relationship, the value that you select for the `-identity-preserve` option of the `snapmirror create` command determines the configuration details that are replicated in the destination SVM.

If you set the `-identity-preserve` option to `true` (ID-preserve), the SMB signing security setting is replicated to the destination.

If you set the `-identity-preserve` option to `false` (non-ID-preserve), the SMB signing security setting is not replicated to the destination. In this case, the CIFS server security settings on the destination are set to the default values. If you have enabled required SMB signing on the source SVM, you must manually enable required SMB signing on the destination SVM.

Steps

1. Perform one of the following actions:

If you want required SMB signing to be...	Enter the command...
Enabled	<code>vserver cifs security modify -vserver vserver_name -is-signing-required true</code>
Disabled	<code>vserver cifs security modify -vserver vserver_name -is-signing-required false</code>

2. Verify that required SMB signing is enabled or disabled by determining whether the value in the `Is Signing Required` field in the output of the following command is set to the desired value: `vserver cifs security show -vserver vserver_name -fields is-signing-required`

Example

The following example enables required SMB signing for SVM vs1:

```
cluster1::> vserver cifs security modify -vserver vs1 -is-signing-required true

cluster1::> vserver cifs security show -vserver vs1 -fields is-signing-required
vserver  is-signing-required
-----
vs1      true
```

Determine whether SMB sessions are signed

You can display information about connected SMB sessions on the CIFS server. You can use this information to determine whether SMB sessions are signed. This can be helpful in determining whether SMB client sessions are connecting with the desired security settings.

Steps

1. Perform one of the following actions:

If you want display information about...	Enter the command...
All signed sessions on a specified storage virtual machine (SVM)	vserver cifs session show -vserver <i>vserver_name</i> -is-session-signed true
Details for a signed session with a specific session ID on the SVM	vserver cifs session show -vserver <i>vserver_name</i> -session-id <i>integer</i> -instance

Examples

The following command displays session information about signed sessions on SVM vs1. The default summary output does not display the “Is Session Signed” output field:

```
cluster1::> vserver cifs session show -vserver vs1 -is-session-signed true
Node:    node1
Vserver: vs1
Connection Session
ID       ID       Workstation          Windows User      Open   Idle
-----  -----  -----
3151272279  1       10.1.1.1        DOMAIN\joe      2      23s
```

The following command displays detailed session information, including whether the session is signed, on an SMB session with a session ID of 2:

```
cluster1::> vserver cifs session show -vserver vs1 -session-id 2 -instance
          Node: node1
          Vserver: vs1
          Session ID: 2
          Connection ID: 3151274158
Incoming Data LIF IP Address: 10.2.1.1
          Workstation: 10.1.1.2
Authentication Mechanism: Kerberos
          Windows User: DOMAIN\joe
          UNIX User: pcuser
          Open Shares: 1
          Open Files: 1
          Open Other: 0
Connected Time: 10m 43s
          Idle Time: 1m 19s
Protocol Version: SMB3
Continuously Available: No
          Is Session Signed: true
User Authenticated as: domain-user
          NetBIOS Name: CIFS_ALIAS1
SMB Encryption Status: Unencrypted
```

Related information

[Monitoring SMB signed session statistics](#)

Monitor SMB signed session statistics

You can monitor SMB sessions statistics and determine which established sessions are signed and which are not.

About this task

The `statistics` command at the advanced privilege level provides the `signed_sessions` counter that you can use to monitor the number of signed SMB sessions. The `signed_sessions` counter is available with the following statistics objects:

- `cifs` enables you to monitor SMB signing for all SMB sessions.
- `smb1` enables you to monitor SMB signing for SMB 1.0 sessions.
- `smb2` enables you to monitor SMB signing for SMB 2.x and SMB 3.0 sessions.

SMB 3.0 statistics are included in the output for the `smb2` object.

If you want to compare the number of signed session to the total number of sessions, you can compare output for the `signed_sessions` counter with the output for the `established_sessions` counter.

You must start a statistics sample collection before you can view the resultant data. You can view data from the

sample if you do not stop data collection. Stopping data collection gives you a fixed sample. Not stopping data collection gives you the ability to get updated data that you can use to compare against previous queries. The comparison can help you identify trends.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Start a data collection: `statistics start -object {cifs|smb1|smb2} -instance instance -sample-id sample_ID [-node node_name]`

If you do not specify the `-sample-id` parameter, the command generates a sample identifier for you and defines this sample as the default sample for the CLI session. The value for `-sample-id` is a text string. If you run this command during the same CLI session and do not specify the `-sample-id` parameter, the command overwrites the previous default sample.

You can optionally specify the node on which you want to collect statistics. If you do not specify the node, the sample collects statistics for all nodes in the cluster.

3. Use the `statistics stop` command to stop collecting data for the sample.
4. View SMB signing statistics:

If you want to view information for...	Enter...
Signed sessions	<code>show -sample-id sample_ID -counter signed_sessions node_name [-node node_name]</code>
Signed sessions and established sessions	<code>show -sample-id sample_ID -counter signed_sessions established_sessions node_name [-node node_name]</code>

If you want to display information for only a single node, specify the optional `-node` parameter.

5. Return to the admin privilege level: `set -privilege admin`

Examples

The following example shows how you can monitor SMB 2.x and SMB 3.0 signing statistics on storage virtual machine (SVM) vs1.

The following command moves to the advanced privilege level:

```
cluster1::> set -privilege advanced
```

Warning: These advanced commands are potentially dangerous; use them only when directed to do so by support personnel.

Do you want to continue? {y|n}: y

The following command starts data collection for a new sample:

```
cluster1::*> statistics start -object smb2 -sample-id smbsigning_sample  
-vserver vs1  
Statistics collection is being started for Sample-id: smbsigning_sample
```

The following command stops the data collection for the sample:

```
cluster1::*> statistics stop -sample-id smbsigning_sample  
Statistics collection is being stopped for Sample-id: smbsigning_sample
```

The following command shows signed SMB sessions and established SMB sessions by node from the sample:

```
cluster1::*> statistics show -sample-id smbsigning_sample -counter  
signed_sessions|established_sessions|node_name
```

Object: smb2
Instance: vs1
Start-time: 2/6/2013 01:00:00
End-time: 2/6/2013 01:03:04
Cluster: cluster1

Counter	Value
-----	-----
established_sessions	0
node_name	node1
signed_sessions	0
established_sessions	1
node_name	node2
signed_sessions	1
established_sessions	0
node_name	node3
signed_sessions	0
established_sessions	0
node_name	node4
signed_sessions	0

The following command shows signed SMB sessions for node2 from the sample:

```
cluster1::*> statistics show -sample-id smbsigning_sample -counter signed_sessions|node_name -node node2
```

```
Object: smb2
Instance: vs1
Start-time: 2/6/2013 01:00:00
End-time: 2/6/2013 01:22:43
Cluster: cluster1
```

Counter	Value
<hr/>	
node_name	node2
signed_sessions	1

The following command moves back to the admin privilege level:

```
cluster1::*> set -privilege admin
```

[Determining whether SMB sessions are signed](#)

[Performance monitoring express setup](#)

[Configure required SMB encryption on SMB servers for data transfers over SMB](#)

[Configure required SMB encryption on SMB servers for data transfers over SMB overview](#)

SMB encryption for data transfers over SMB is a security enhancement that you can enable or disable on SMB servers. You can also configure the desired SMB encryption setting on a share-by-share basis through a share property setting.

By default, when you create a SMB server on the storage virtual machine (SVM), SMB encryption is disabled. You must enable it to take advantage of the enhanced security provided by SMB encryption.

To create an encrypted SMB session, the SMB client must support SMB encryption. Windows clients beginning with Windows Server 2012 and Windows 8 support SMB encryption.

SMB encryption on the SVM is controlled through two settings:

- A SMB server security option that enables the functionality on the SVM
- A SMB share property that configures the SMB encryption setting on a share-by-share basis

You can decide whether to require encryption for access to all data on the SVM or to require SMB encryption to access data only in selected shares. SVM-level settings supersede share-level settings.

The effective SMB encryption configuration depends on the combination of the two settings and is described in the following table:

SMB server SMB encryption enabled	Share encrypt data setting enabled	Server-side encryption behavior
True	False	Server-level encryption is enabled for all of the shares in the SVM. With this configuration, encryption happens for the entire SMB session.
True	True	Server-level encryption is enabled for all of the shares in the SVM irrespective of share-level encryption. With this configuration, encryption happens for the entire SMB session.
False	True	Share-level encryption is enabled for the specific shares. With this configuration, encryption happens from the tree connect.
False	False	No encryption is enabled.

SMB clients that do not support encryption cannot connect to a SMB server or share that requires encryption.

Performance impact of SMB encryption

When SMB sessions use SMB encryption, all SMB communications to and from Windows clients experience a performance impact, which affects both the clients and the server (that is, the nodes on the cluster running the SVM that contains the SMB server).

The performance impact shows as increased CPU usage on both the clients and the server, although the amount of network traffic does not change.

The extent of the performance impact depends on the version of ONTAP 9 you are running. Beginning with ONTAP 9.7, a new encryption off-load algorithm can enable better performance in encrypted SMB traffic. SMB encryption offload is enabled by default when SMB encryption is enabled.

Enhanced SMB encryption performance requires AES-NI offload capability. See the Hardware Universe (HWU) to verify that AES-NI offload is supported for your platform.

Further performance improvements are also possible if you are able to use SMB version 3.11 (supported with Windows 10 and Windows Server 2016), which supports the much faster GCM algorithm.

Depending on your network, ONTAP 9 version, SMB version, and SVM implementation, the performance impact of SMB encryption can vary widely; you can verify it only through testing in your network environment.

SMB encryption is disabled by default on the SMB server. You should enable SMB encryption only on those SMB shares or SMB servers that require encryption. With SMB encryption, ONTAP performs additional processing of decrypting the requests and encrypting the responses for every request. SMB encryption should therefore be enabled only when necessary.

Enable or disable required SMB encryption for incoming SMB traffic

If you want to require SMB encryption for incoming SMB traffic you can enable it on the CIFS server or at the share level. By default, SMB encryption is not required.

About this task

You can enable SMB encryption on the CIFS server, which applies to all shares on the CIFS server. If you do not want required SMB encryption for all shares on the CIFS server or if you want to enable required SMB encryption for incoming SMB traffic on a share-by-share basis, you can disable required SMB encryption on the CIFS server.

When you set up a storage virtual machine (SVM) disaster recovery relationship, the value you select for the `-identity-preserve` option of the `snapmirror create` command determines the configuration details that are replicated in the destination SVM.

If you set the `-identity-preserve` option to `true` (ID-preserve), the SMB encryption security setting is replicated to the destination.

If you set the `-identity-preserve` option to `false` (non-ID-preserve), the SMB encryption security setting is not replicated to the destination. In this case, the CIFS server security settings on the destination are set to the default values. If you have enabled SMB encryption on the source SVM, you must manually enable CIFS server SMB encryption on the destination.

Steps

1. Perform one of the following actions:

If you want required SMB encryption for incoming SMB traffic on the CIFS server to be...	Enter the command...
Enabled	<pre>vserver cifs security modify -vserver vserver_name -is-smb-encryption -required true</pre>
Disabled	<pre>vserver cifs security modify -vserver vserver_name -is-smb-encryption -required false</pre>

2. Verify that required SMB encryption on the CIFS server is enabled or disabled as desired: `vserver cifs security show -vserver vserver_name -fields is-smb-encryption-required`

The `is-smb-encryption-required` field displays `true` if required SMB encryption is enabled on the CIFS server and `false` if it is disabled.

Example

The following example enables required SMB encryption for incoming SMB traffic for the CIFS server on SVM vs1:

```

cluster1::> vserver cifs security modify -vserver vs1 -is-smb-encryption
-required true

cluster1::> vserver cifs security show -vserver vs1 -fields is-smb-
encryption-required
vserver  is-smb-encryption-required
-----
vs1      true

```

Determine whether clients are connected using encrypted SMB sessions

You can display information about connected SMB sessions to determine whether clients are using encrypted SMB connections. This can be helpful in determining whether SMB client sessions are connecting with the desired security settings.

About this task

SMB clients sessions can have one of three encryption levels:

- unencrypted

The SMB session is not encrypted. Neither storage virtual machine (SVM)-level or share-level encryption is configured.

- partially-encrypted

Encryption is initiated when the tree-connect occurs. Share-level encryption is configured. SVM-level encryption is not enabled.

- encrypted

The SMB session is fully encrypted. SVM-level encryption is enabled. Share level encryption might or might not be enabled. The SVM-level encryption setting supersedes the share-level encryption setting.

Steps

1. Perform one of the following actions:

If you want display information about...	Enter the command...
Sessions with a specified encryption setting for sessions on a specified SVM	vserver cifs session show -vserver <i>vserver_name</i> {unencrypted partially-encrypted encrypted} -instance
The encryption setting for a specific session ID on a specified SVM	vserver cifs session show -vserver <i>vserver_name</i> -session-id <i>integer</i> -instance

Examples

The following command displays detailed session information, including the encryption setting, on an SMB session with a session ID of 2:

```
cluster1::> vserver cifs session show -vserver vs1 -session-id 2 -instance
              Node: node1
              Vserver: vs1
              Session ID: 2
              Connection ID: 3151274158
Incoming Data LIF IP Address: 10.2.1.1
              Workstation: 10.1.1.2
Authentication Mechanism: Kerberos
              Windows User: DOMAIN\joe
              UNIX User: pcuser
Open Shares: 1
              Open Files: 1
              Open Other: 0
Connected Time: 10m 43s
              Idle Time: 1m 19s
Protocol Version: SMB3
Continuously Available: No
Is Session Signed: true
User Authenticated as: domain-user
NetBIOS Name: CIFS_ALIAS1
SMB Encryption Status: Unencrypted
```

Monitor SMB encryption statistics

You can monitor SMB encryption statistics and determine which established sessions and share connections are encrypted and which are not.

About this task

The `statistics` command at the advanced privilege level provides the following counters, which you can use to monitor the number of encrypted SMB sessions and share connections:

Counter name	Descriptions
encrypted_sessions	Gives the number of encrypted SMB 3.0 sessions
encrypted_share_connections	Gives the number of encrypted shares on which a tree connect has happened
rejected_unencrypted_sessions	Gives the number of session setups rejected due to a lack of client encryption capability
rejected_unencrypted_shares	Gives the number of share mappings rejected due to a lack of client encryption capability

These counters are available with the following statistics objects:

- `cifs` enables you to monitor SMB encryption for all SMB 3.0 sessions.

SMB 3.0 statistics are included in the output for the `cifs` object. If you want to compare the number of encrypted sessions to the total number of sessions, you can compare output for the `encrypted_sessions` counter with the output for the `established_sessions` counter.

If you want to compare the number of encrypted share connections to the total number of share connections, you can compare output for the `encrypted_share_connections` counter with the output for the `connected_shares` counter.

- `rejected_unencrypted_sessions` provides the number of times an attempt has been made to establish an SMB session that requires encryption from a client that does not support SMB encryption.
- `rejected_unencrypted_shares` provides the number of times an attempt has been made to connect to an SMB share that requires encryption from a client that does not support SMB encryption.

You must start a statistics sample collection before you can view the resultant data. You can view data from the sample if you do not stop the data collection. Stopping data collection gives you a fixed sample. Not stopping data collection gives you the ability to get updated data that you can use to compare against previous queries. The comparison can help you identify trends.

Performance management

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Start a data collection: `statistics start -object {cifs|smb1|smb2} -instance instance -sample-id sample_ID [-node node_name]`

If you do not specify the `-sample-id` parameter, the command generates a sample identifier for you and defines this sample as the default sample for the CLI session. The value for `-sample-id` is a text string. If you run this command during the same CLI session and do not specify the `-sample-id` parameter, the command overwrites the previous default sample.

You can optionally specify the node on which you want to collect statistics. If you do not specify the node, the sample collects statistics for all nodes in the cluster.

3. Use the `statistics stop` command to stop collecting data for the sample.
4. View SMB encryption statistics:

If you want to view information for...	Enter...
Encrypted sessions	<code>show -sample-id <i>sample_ID</i> -counter encrypted_sessions <i>node_name</i> [-node <i>node_name</i>]</code>

If you want to view information for...	Enter...
Encrypted sessions and established sessions	show -sample-id <i>sample_ID</i> -counter encrypted_sessions established_sessions node_name [-node <i>node_name</i>]
Encrypted share connections	show -sample-id <i>sample_ID</i> -counter encrypted_share_connections node_name [-node <i>node_name</i>]
Encrypted share connections and connected shares	show -sample-id <i>sample_ID</i> -counter encrypted_share_connections connected_shares node_name [-node <i>node_name</i>]
Rejected unencrypted sessions	show -sample-id <i>sample_ID</i> -counter rejected_unencrypted_sessions node_name [-node <i>node_name</i>]
Rejected unencrypted share connections	show -sample-id <i>sample_ID</i> -counter rejected_unencrypted_share node_name [-node <i>node_name</i>]

If you want to display information only for a single node, specify the optional `-node` parameter.

5. Return to the admin privilege level: `set -privilege admin`

Examples

The following example shows how you can monitor SMB 3.0 encryption statistics on storage virtual machine (SVM) vs1.

The following command moves to the advanced privilege level:

```
cluster1::> set -privilege advanced
```

Warning: These advanced commands are potentially dangerous; use them only when directed to do so by support personnel.

Do you want to continue? {y|n}: y

The following command starts data collection for a new sample:

```
cluster1::*> statistics start -object cifs -sample-id smbencryption_sample
-vserver vs1
Statistics collection is being started for Sample-id: smbencryption_sample
```

The following command stops data collection for that sample:

```
cluster1::>* statistics stop -sample-id smbencryption_sample
Statistics collection is being stopped for Sample-id: smbencryption_sample
```

The following command shows encrypted SMB sessions and established SMB sessions by the node from the sample:

```
cluster2::>* statistics show -object cifs -counter
established_sessions|encrypted_sessions|node_name -node node_name

Object: cifs
Instance: [proto_ctx:003]
Start-time: 4/12/2016 11:17:45
End-time: 4/12/2016 11:21:45
Scope: vsim2

      Counter          Value
-----  -----
established_sessions           1
encrypted_sessions             1

2 entries were displayed
```

The following command shows the number of rejected unencrypted SMB sessions by the node from the sample:

```
clus-2::>* statistics show -object cifs -counter
rejected_unencrypted_sessions -node node_name

Object: cifs
Instance: [proto_ctx:003]
Start-time: 4/12/2016 11:17:45
End-time: 4/12/2016 11:21:51
Scope: vsim2

      Counter          Value
-----  -----
rejected_unencrypted_sessions           1

1 entry was displayed.
```

The following command shows the number of connected SMB shares and encrypted SMB shares by the node from the sample:

```

clus-2::*> statistics show -object cifs -counter
connected_shares|encrypted_share_connections|node_name -node node_name

Object: cifs
Instance: [proto_ctx:003]
Start-time: 4/12/2016 10:41:38
End-time: 4/12/2016 10:41:43
Scope: vsim2

      Counter          Value
-----  -----
connected_shares           2
encrypted_share_connections 1

2 entries were displayed.

```

The following command shows the number of rejected unencrypted SMB share connections by the node from the sample:

```

clus-2::*> statistics show -object cifs -counter
rejected_unencrypted_shares -node node_name

Object: cifs
Instance: [proto_ctx:003]
Start-time: 4/12/2016 10:41:38
End-time: 4/12/2016 10:42:06
Scope: vsim2

      Counter          Value
-----  -----
rejected_unencrypted_shares        1

1 entry was displayed.

```

[Performance monitoring express setup](#)

[Secure LDAP session communication](#)

LDAP signing and sealing concepts

Beginning with ONTAP 9, you can configure signing and sealing to enable LDAP session security on queries to an Active Directory (AD) server. You must configure the CIFS

server security settings on the storage virtual machine (SVM) to correspond to those on the LDAP server.

Siging confirms the integrity of the LDAP payload data using secret key technology. Sealing encrypts the LDAP payload data to avoid transmitting sensitive information in clear text. An *LDAP Security Level* option indicates whether the LDAP traffic needs to be signed, signed and sealed, or neither. The default is `none`.

LDAP signing and sealing on CIFS traffic is enabled on the SVM with the `-session-security-for-ad-ldap` option to the `vserver cifs security modify` command.

Enable LDAP signing and sealing on the CIFS server

Before your CIFS server can use signing and sealing for secure communication with an Active Directory LDAP server, you must modify the CIFS server security settings to enable LDAP signing and sealing.

Before you begin

You must consult with your AD server administrator to determine the appropriate security configuration values.

Steps

1. Configure the CIFS server security setting that enables signed and sealed traffic with Active Directory LDAP servers:
`vserver cifs security modify -vserver vserver_name -session-security-for-ad-ldap {none|sign|seal}`

You can enable signing (sign, data integrity), signing and sealing (seal, data integrity and encryption), or neither (none, no signing or sealing). The default value is `none`.

2. Verify that the LDAP signing and sealing security setting is set correctly:
`vserver cifs security show -vserver vserver_name`

If the SVM uses the same LDAP server for querying name-mapping or other UNIX information, such as users, groups, and netgroups, then you must enable the corresponding setting with the `-session-security` option of the `vserver services name-service ldap client modify` command.

Configure LDAP over TLS

Export a copy of the self-signed root CA certificate

To use LDAP over SSL/TLS for securing Active Directory communication, you must first export a copy of the Active Directory Certificate Service's self-signed root CA certificate to a certificate file and convert it to an ASCII text file. This text file is used by ONTAP to install the certificate on the storage virtual machine (SVM).

Before you begin

The Active Directory Certificate Service must already be installed and configured for the domain to which the CIFS server belongs. You can find information about installing and configuring Active Director Certificate Services by consulting the Microsoft TechNet Library.

Step

1. Obtain a root CA certificate of the domain controller that is in the .pem text format.

Microsoft TechNet Library: technet.microsoft.com

After you finish

Install the certificate on the SVM.

Related information

[Microsoft TechNet Library](#)

Install the self-signed root CA certificate on the SVM

If LDAP authentication with TLS is required when binding to LDAP servers, you must first install the self-signed root CA certificate on the SVM.

About this task

When LDAP over TLS is enabled, the ONTAP LDAP client on the SVM does not support revoked certificates in ONTAP 9.0 and 9.1.

Beginning with ONTAP 9.2, all applications within ONTAP that use TLS communications can check digital certificate status using Online Certificate Status Protocol (OCSP). If OCSP is enabled for LDAP over TLS, revoked certificates are rejected and the connection fails.

Steps

1. Install the self-signed root CA certificate:

a. Begin the certificate installation: `security certificate install -vserver vserver_name -type server-ca`

The console output displays the following message: Please enter Certificate: Press <Enter> when done

b. Open the certificate .pem file with a text editor, copy the certificate, including the lines beginning with -----BEGIN CERTIFICATE----- and ending with -----END CERTIFICATE-----, and then paste the certificate after the command prompt.

- c. Verify that the certificate is displayed correctly.
- d. Complete the installation by pressing Enter.

2. Verify that the certificate is installed: `security certificate show -vserver vserver_name`

Enable LDAP over TLS on the server

Before your SMB server can use TLS for secure communication with an Active Directory LDAP server, you must modify the SMB server security settings to enable LDAP over TLS.

Beginning with ONTAP 9.10.1, LDAP channel binding is supported by default for both Active Directory (AD) and name services LDAP connections. ONTAP will try channel binding with LDAP connections only if Start-TLS or LDAPS is enabled along with session security set to either sign or seal. To disable or reenable LDAP channel binding with AD servers, use the `--try-channel-binding-for-ad-ldap` parameter with the

cifs security modify command.

For more information, see

[2020 LDAP channel binding and LDAP signing requirements for Windows](#).

Steps

1. Configure the SMB server security setting that allows secure LDAP communication with Active Directory LDAP servers: vserver cifs security modify -vserver vserver_name -use-start-tls -for-ad-ldap true
2. Verify that the LDAP over TLS security setting is set to true: vserver cifs security show -vserver vserver_name

If the SVM uses the same LDAP server for querying name-mapping or other UNIX information (such as users, groups, and netgroups), then you must also modify the -use-start-tls option by using the vserver services name-service ldap client modify command.

[LDAPS concepts](#)

[NFS management](#)

Configure SMB Multichannel for performance and redundancy

Beginning with ONTAP 9.4, you can configure SMB Multichannel to provide multiple connections between ONTAP and clients in a single SMB session. Doing so improves throughput and fault tolerance.

Before you begin

You can use SMB Multichannel functionality only when clients negotiate at SMB 3.0 or later versions. SMB 3.0 and later is enabled on the ONTAP SMB server by default.

About this task

SMB clients automatically detect and use multiple network connections if a proper configuration is identified on the ONTAP cluster.

The number of simultaneous connections in an SMB session depends on the NICs you have deployed:

- **1G NICs on client and ONTAP cluster**

The client establishes one connection per NIC and binds the session to all connections.

- **10G and larger capacity NICs on client and ONTAP cluster**

The client establishes up to four connections per NIC and binds the session to all connections. The client can establish connections on multiple 10G and larger capacity NICs.

You can also modify the following parameters (advanced privilege):

- **-max-connections-per-session**

The maximum number of connections allowed per Multichannel session. The default is 32 connections.

If you want to enable more connections than the default, you must make comparable adjustments to the client configuration, which also has a default of 32 connections.

- **-max-lifs-per-session**

The maximum number of network interfaces advertised per Multichannel session. The default is 256 network interfaces.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Enable SMB Multichannel on the SMB server: `vserver cifs options modify -vserver vserver_name -is-multichannel-enabled true`
3. Verify that ONTAP is reporting SMB Multichannel sessions: `vserver cifs session show options`
4. Return to the admin privilege level: `set -privilege admin`

Example

The following example displays information about all SMB sessions, showing multiple connections for a single session:

```
cluster1::> vserver cifs session show
Node:      node1
Vserver:   vs1
Connection Session                                Open
Idle
IDs        ID       Workstation      Windows User      Files
Time
-----
-----
138683,
138684,
138685      1       10.1.1.1        DOMAIN\          0
4s
                                         Administrator
```

The following example displays detailed information about an SMB session with session-id 1:

```
cluster1::> vserver cifs session show -session-id 1 -instance

Vserver: vs1
          Node: node1
          Session ID: 1
          Connection IDs: 138683,138684,138685
          Connection Count: 3
          Incoming Data LIF IP Address: 192.1.1.1
          Workstation IP Address: 10.1.1.1
          Authentication Mechanism: NTLMv1
          User Authenticated as: domain-user
          Windows User: DOMAIN\administrator
          UNIX User: root
          Open Shares: 2
          Open Files: 5
          Open Other: 0
          Connected Time: 5s
          Idle Time: 5s
          Protocol Version: SMB3
          Continuously Available: No
          Is Session Signed: false
          NetBIOS Name: -
```

Configure default Windows user to UNIX user mappings on the SMB server

Configure the default UNIX user

You can configure the default UNIX user to use if all other mapping attempts fail for a user, or if you do not want to map individual users between UNIX and Windows. Alternatively, if you want authentication of non-mapped users to fail, you should not configure the default UNIX user.

About this task

By default, the name of the default UNIX user is “pcuser”, which means that, by default, user mapping to the default UNIX user is enabled. You can specify another name to use as the default UNIX user. The name that you specify must exist in the name service databases configured for the storage virtual machine (SVM). If this option is set to a null string, no one can access the CIFS server as a UNIX default user. That is, each user must have an account in the password database before they can access the CIFS server.

For a user to connect to the CIFS server using the default UNIX user account, the user must meet the following prerequisites:

- The user is authenticated.
- The user is in the CIFS server’s local Windows user database, in the CIFS server’s home domain, or in a trusted domain (if multidomain name mapping searches is enabled on the CIFS server).
- The user name is not explicitly mapped to a null string.

Steps

1. Configure the default UNIX user:

If you want to ...	Enter ...
Use the default UNIX user “pcuser”	vserver cifs options modify -default -unix-user pcuser
Use another UNIX user account as the default user	vserver cifs options modify -default -unix-user <i>user_name</i>
Disable the default UNIX user	vserver cifs options modify -default -unix-user ""

```
vserver cifs options modify -default-unix-user pcuser
```

2. Verify that the default UNIX user is configured correctly: vserver cifs options show -vserver *vserver_name*

In the following example, both the default UNIX user and the guest UNIX user on SVM vs1 are configured to use UNIX user “pcuser”:

```
vserver cifs options show -vserver vs1
```

```
Vserver: vs1

Client Session Timeout : 900
Default Unix Group    : -
Default Unix User     : pcuser
Guest Unix User       : pcuser
Read Grants Exec      : disabled
Read Only Delete      : disabled
WINS Servers          : -
```

Configure the guest UNIX user

Configuring the guest UNIX user option means that users who log in from untrusted domains are mapped to the guest UNIX user and can connect to the CIFS server. Alternatively, if you want authentication of users from untrusted domains to fail, you should not configure the guest UNIX user. The default is to not allow users from untrusted domains to connect to the CIFS server (the guest UNIX account is not configured).

About this task

You should keep the following in mind when configuring the guest UNIX account:

- If the CIFS server cannot authenticate the user against a domain controller for the home domain or a trusted domain or the local database and this option is enabled, the CIFS server considers the user as a

guest user and maps the user to the specified UNIX user.

- If this option is set to a null string, the guest UNIX user is disabled.
- You must create a UNIX user to use as the guest UNIX user in one of the storage virtual machine (SVM) name service databases.
- A user logged in as a guest user is automatically a member of the BUILTIN\guests group on the CIFS server.
- The 'homedirs-public' option applies only to authenticated users. A user logged in as a guest user does not have a home directory and cannot access other users' home directories.

Steps

1. Perform one of the following actions:

If you want to...	Enter...
Configure the guest UNIX user	vserver cifs options modify -guest -unix-user <i>unix_name</i>
Disable the guest UNIX user	vserver cifs options modify -guest -unix-user ""

```
vserver cifs options modify -guest-unix-user pcuser
```

2. Verify that the guest UNIX user is configured correctly: `vserver cifs options show -vserver vserver_name`

In the following example, both the default UNIX user and the guest UNIX user on SVM vs1 are configured to use UNIX user "pcuser":

```
vserver cifs options show -vserver vs1
```

```
Vserver: vs1

Client Session Timeout : 900
Default Unix Group    : -
Default Unix User     : pcuser
Guest Unix User       : pcuser
Read Grants Exec      : disabled
Read Only Delete      : disabled
WINS Servers          : -
```

Map the administrators group to root

If you have only CIFS clients in your environment and your storage virtual machine (SVM) was set up as a multiprotocol storage system, you must have at least one Windows account that has root privilege for accessing files on the SVM; otherwise, you cannot manage the SVM because you do not have sufficient user rights.

About this task

If your storage system was set up as NTFS-only, however, the `/etc` directory has a file-level ACL that enables the administrators group to access the ONTAP configuration files.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Configure the CIFS server option that maps the administrators group to root as appropriate:

If you want to...	Then...
Map the administrator group members to root	<code>vserver cifs options modify -vserver vserver_name -is-admin-users-mapped-to-root-enabled true</code> All accounts in the administrators group are considered root, even if you do not have an <code>/etc/usermap.cfg</code> entry mapping the accounts to root. If you create a file using an account that belongs to the administrators group, the file is owned by root when you view the file from a UNIX client.
Disable mapping the administrators group members to root	<code>vserver cifs options modify -vserver vserver_name -is-admin-users-mapped-to-root-enabled false</code> Accounts in the administrators group no longer map to root. You can only explicitly map a single user to root.

3. Verify that the option is set to the desired value: `vserver cifs options show -vserver vserver_name`
4. Return to the admin privilege level: `set -privilege admin`

Display information about what types of users are connected over SMB sessions

You can display information about what type of users are connected over SMB sessions. This can help you ensure that only the appropriate type of user is connecting over SMB sessions on the storage virtual machine (SVM).

About this task

The following types of users can connect over SMB sessions:

- local-user

Authenticated as a local CIFS user

- domain-user

Authenticated as a domain user (either from the CIFS server's home domain or a trusted domain)

- guest-user

Authenticated as a guest user

- anonymous-user

Authenticated as an anonymous or null user

Steps

1. Determine what type of user is connected over an SMB session: `vserver cifs session show -vserver vserver_name -windows-user windows_user_name -fields windows-user,address,lif-address,user-type`

If you want to display user type information for established sessions...	Enter the following command...
For all sessions with a specified user type	<code>vserver cifs session show -vserver vserver_name -user-type {local-user domain-user guest-user anonymous-user}</code>
For a specific user	<code>vserver cifs session show -vserver vserver_name -windows-user windows_user_name -fields windows-user,address,lif-address,user-type</code>

Examples

The following command displays session information on the user type for sessions on SVM vs1 established by user "``iepubs\user1``":

```
cluster1::> vserver cifs session show -vserver pub1 -windows-user
iepubs\user1 -fields windows-user,address,lif-address,user-type
node      vserver session-id connection-id lif-address address
windows-user      user-type
-----
-----
pub1node1 pub1      1          3439441860      10.0.0.1      10.1.1.1
IEPUBS\user1      domain-user
```

Command options to limit excessive Windows client resource consumption

Options to the `vserver cifs` options modify command enable you to control resource consumption for Windows clients. This can be helpful if any clients are outside normal bounds of resource consumption, for example, if there are unusually high numbers of files open, sessions open, or change notify requests.

The following options to the `vserver cifs` options modify command have been added to control Windows client resource consumption. If the maximum value for any of these options is exceeded, the request is denied and an EMS message is sent. An EMS warning message is also sent when 80 percent of the configured limit for these options is reached.

- `-max-opens-same-file-per-tree`
Maximum number of opens on the same file per CIFS tree
- `-max-same-user-sessions-per-connection`
Maximum number of sessions opened by the same user per connection
- `-max-same-tree-connect-per-session`
Maximum number of tree connects on the same share per session
- `-max-watches-set-per-tree`
Maximum number of watches (also known as *change notifies*) established per tree

See the man pages for the default limits and to display the current configuration.

Beginning with ONTAP 9.4, servers running SMB version 2 or later can limit the number of outstanding requests (*SMB credits*) that the client can send to the server on a SMB connection. The management of SMB credits is initiated by the client and controlled by the server.

The maximum number of outstanding requests that can be granted on an SMB connection is controlled by the `-max-credits` option. The default value for this option is 128.

Improve client performance with traditional and lease oplocks

Improve client performance with traditional and lease oplocks overview

Traditional oplocks (opportunistic locks) and lease oplocks enable an SMB client in certain file-sharing scenarios to perform client-side caching of read-ahead, write-behind, and lock information. A client can then read from or write to a file without regularly reminding the server that it needs access to the file in question. This improves performance by reducing network traffic.

Lease oplocks are an enhanced form of oplocks available with the SMB 2.1 protocol and later. Lease oplocks allow a client to obtain and preserve client caching state across multiple SMB opens originating from itself.

Oplocks can be controlled in two ways:

- By a share property, using the `vserver cifs share create` command when the share is created, or the `vserver share properties` command after creation.
- By a qtree property, using the `volume qtree create` command when the qtree is created, or the `volume qtree oplock` commands after creation.

Write cache data-loss considerations when using oplocks

Under some circumstances, if a process has an exclusive oplock on a file and a second process attempts to open the file, the first process must invalidate cached data and flush writes and locks. The client must then relinquish the oplock and access to the file. If there is a network failure during this flush, cached write data might be lost.

- Data-loss possibilities

Any application that has write-cached data can lose that data under the following set of circumstances:

- The connection is made using SMB 1.0.
- It has an exclusive oplock on the file.
- It is told to either break that oplock or close the file.
- During the process of flushing the write cache, the network or target system generates an error.

- Error handling and write completion

The cache itself does not have any error handling—the applications do. When the application makes a write to the cache, the write is always completed. If the cache, in turn, makes a write to the target system over a network, it must assume that the write is completed because if it does not, the data is lost.

Enable or disable oplocks when creating SMB shares

Oplocks allow clients to lock files and cache content locally, which can increase performance for file operations. Oplocks are enabled on SMB shares residing on storage virtual machines (SVMs). In some circumstances, you might want to disable oplocks. You can enable or disable oplocks on a share-by-share basis.

About this task

If oplocks are enabled on the volume containing a share but the oplock share property for that share is disabled, oplocks are disabled for that share. Disabling oplocks on a share takes precedence over the volume oplock setting. Disabling oplocks on the share disables both opportunistic and lease oplocks.

You can specify other share properties in addition to specifying the oplock share property by using a comma-delimited list. You can also specify other share parameters.

Steps

1. Perform the applicable action:

If you want to...	Then...
Enable oplocks on a share during share creation	<p>Enter the following command:</p> <pre>vserver cifs share create -vserver _vserver_name_ -share-name share_name -path path_to_share -share-properties [oplocks,...]</pre> <p> If you want the share to have only the default share properties, which are oplocks, browsable, and changenotify enabled, you do not have to specify the -share-properties parameter when creating an SMB share. If you want any combination of share properties other than the default, then you must specify the -share-properties parameter with the list of share properties to use for that share.</p>
Disable oplocks on a share during share creation	<p>Enter the following command:</p> <pre>vserver cifs share create -vserver _vserver_name_ -share-name _share_name_ -path _path_to_share_ -share-properties [other_share_property,...]</pre> <p> When disabling oplocks, you must specify a list of share properties when creating the share, but you should not specify the oplocks property.</p>

Commands for enabling or disabling oplocks on volumes and qtrees

Oplocks allow clients to lock files and cache content locally, which can increase performance for file operations. You need to know the commands for enabling or disabling oplocks on volumes or qtrees. You also must know when you can enable or disable oplocks on volumes and qtrees.

- Oplocks are enabled on volumes by default.
- You cannot disable oplocks when you create a volume.
- You can enable or disable oplocks on existing volumes for SVMs at any time.

- You can enable oplocks on qtrees for SVMs.

The oplock mode setting is a property of qtree ID 0, the default qtree that all volumes have. If you do not specify an oplock setting when creating a qtree, the qtree inherits the oplock setting of the parent volume, which is enabled by default. However, if you do specify an oplock setting on the new qtree, it takes precedence over the oplock setting on the volume.

If you want to...	Use this command...
Enable oplocks on volumes or qtrees	<code>volume qtree oplocks with the -oplock-mode parameter set to enable</code>

[Monitoring oplock status](#)

Enable or disable oplocks on existing SMB shares

Oplocks are enabled on SMB shares on storage virtual machines (SVMs) by default. Under some circumstances, you might want to disable oplocks; alternatively, if you have previously disabled oplocks on a share, you might want to reenable oplocks.

About this task

If oplocks are enabled on the volume containing a share, but the oplock share property for that share is disabled, oplocks are disabled for that share. Disabling oplocks on a share takes precedence over enabling oplocks on the volume. Disabling oplocks on the share, disables both opportunistic and lease oplocks. You can enable or disable oplocks on existing shares at any time.

Step

1. Perform the applicable action:

If you want to...	Then...
Enable oplocks on a share by modifying an existing share	<p>Enter the following command:</p> <pre>vserver share properties add -vserver vserver_name -share-name share_name -share-properties oplocks</pre> <p> You can specify additional share properties to add by using a comma-delimited list.</p> <p>Newly added properties are appended to the existing list of share properties. Any share properties that you have previously specified remain in effect.</p>

If you want to...	Then...
Disable oplocks on a share by modifying an existing share	<p>Enter the following command: <code>vserver share properties remove -vserver vserver_name -share-name share_name -share-properties oplocks</code></p> <p> You can specify additional share properties to remove by using a comma-delimited list.</p> <p>Share properties that you remove are deleted from the existing list of share properties; however, previously configured share properties that you do not remove remain in effect.</p>

Examples

The following command enables oplocks for the share named “Engineering” on storage virtual machine (SVM, formerly known as Vserver) vs1:

```
cluster1::> vserver cifs share properties add -vserver vs1 -share-name Engineering -share-properties oplocks

cluster1::> vserver cifs share properties show
Vserver      Share          Properties
-----
vs1          Engineering    oplocks
                           browsable
                           changenotify
                           showsnapshot
```

The following command disables oplocks for the share named “Engineering” on SVM vs1:

```
cluster1::> vserver cifs share properties remove -vserver vs1 -share-name Engineering -share-properties oplocks

cluster1::> vserver cifs share properties show
Vserver      Share          Properties
-----
vs1          Engineering    browsable
                           changenotify
                           showsnapshot
```

Monitor oplock status

You can monitor and display information about oplock status. You can use this information to determine which files have oplocks, what the oplock level and oplock state level are, and whether oplock leasing is used. You can also determine information about locks that you might need to break manually.

About this task

You can display information about all oplocks in summary form or in a detailed list form. You can also use optional parameters to display information about a smaller subset of existing locks. For example, you can specify that the output return only locks with the specified client IP address or with the specified path.

You can display the following information about traditional and lease oplocks:

- SVM, node, volume, and LIF on which the oplock is established
- Lock UUID
- IP address of the client with the oplock
- Path at which the oplock is established
- Lock protocol (SMB) and type (oplock)
- Lock state
- Oplock level
- Connection state and SMB expiration time
- Open Group ID if a lease oplock is granted

See the `vserver oplocks show` man page for a detailed description of each parameter.

Steps

1. Display oplock status by using the `vserver locks show` command.

Examples

The following command displays default information about all locks. The oplock on the displayed file is granted with a `read-batch` oplock level:

```
cluster1::> vserver locks show

Vserver: vs0
Volume   Object Path          LIF      Protocol  Lock Type  Client
-----  -----
vol1     /vol1/notes.txt      node1_data1
                           cifs      share-level 192.168.1.5
                           Sharelock Mode: read_write-deny_delete
                           op-lock    192.168.1.5
                           Ooplock Level: read-batch
```

The following example displays more detailed information about the lock on a file with the path /data2/data2_2/intro.pptx. A lease oplock is granted on the file with a batch oplock level to a client with an IP address of 10.3.1.3:

When displaying detailed information, the command provides separate output for oplock and sharelock information. This example only shows the output from the oplock section.

```
cluster1::> vserver lock show -instance -path /data2/data2_2/intro.pptx

        Vserver: vs1
        Volume: data2_2
Logical Interface: lif2
        Object Path: /data2/data2_2/intro.pptx
        Lock UUID: ff1cbf29-bfef-4d91-ae06-062bf69212c3
        Lock Protocol: cifs
        Lock Type: op-lock
Node Holding Lock State: node3
        Lock State: granted
Bytelock Starting Offset: -
        Number of Bytes Locked: -
        Bytelock is Mandatory: -
        Bytelock is Exclusive: -
        Bytelock is Superlock: -
        Bytelock is Soft: -
        Oblock Level: batch
Shared Lock Access Mode: -
        Shared Lock is Soft: -
        Delegation Type: -
        Client Address: 10.3.1.3
        SMB Open Type: -
        SMB Connect State: connected
SMB Expiration Time (Secs): -
        SMB Open Group ID:
78a90c59d45ae211998100059a3c7a00a007f70da0f8ffffcd445b0300000000
```

Apply Group Policy Objects to SMB servers

Apply Group Policy Objects to SMB servers overview

Your SMB server supports Group Policy Objects (GPOs), a set of rules known as *group policy attributes* that apply to computers in an Active Directory environment. You can use GPOs to centrally manage settings for all storage virtual machines (SVMs) on the cluster belonging to the same Active Directory domain.

When GPOs are enabled on your SMB server, ONTAP sends LDAP queries to the Active Directory server requesting GPO information. If there are GPO definitions that are applicable to your SMB server, the Active Directory server returns the following GPO information:

- GPO name
- Current GPO version
- Location of the GPO definition
- Lists of UUIDs (universally unique identifiers) for GPO policy sets

Related information

[Securing file access by using Dynamic Access Control \(DAC\)](#)

[SMB and NFS auditing and security tracing](#)

Supported GPOs

Although not all Group Policy Objects (GPOs) are applicable to your CIFS-enabled storage virtual machines (SVMs), SVMs can recognize and process the relevant set of GPOs.

The following GPOs are currently supported on SVMs:

- Advanced audit policy configuration settings:

Object access: Central Access Policy staging

Specifies the type of events to be audited for central access policy (CAP) staging, including the following settings:

- Do not audit
- Audit only success events
- Audit only failure events
- Audit both success and failure events

If any of the three audit options are set (audit only success events, audit only failure events, audit both success and failure events), ONTAP audits both success and failure events.

Set by using the Audit Central Access Policy Staging setting in the Advanced Audit Policy Configuration/Audit Policies/Object Access GPO.

To use advanced audit policy configuration GPO settings, auditing must be configured on the CIFS-enabled SVM to which you want to apply these setting. If auditing is not configured on the SVM, the GPO settings will not be applied and will be dropped.

- Registry settings:

- Group Policy refresh interval for CIFS-enabled SVM

Set by using the Registry GPO.

- Group Policy refresh random offset

Set by using the Registry GPO.

- Hash publication for BranchCache

The Hash Publication for BranchCache GPO corresponds to the BranchCache operating mode. The following three supported operating modes are supported:

- Per-share
- All-shares
- Disabled
Set by using the Registry GPO.

- Hash version support for BranchCache

The following three hash version settings are supported:

- BranchCache version 1
- BranchCache version 2
- BranchCache versions 1 and 2
Set by using the Registry GPO.

To use BranchCache GPO settings, BranchCache must be configured on the CIFS-enabled SVM to which you want to apply these setting. If BranchCache is not configured on the SVM, the GPO settings will not be applied and will be dropped.

- Security settings

- Audit policy and event log
 - Audit logon events

Specifies the type of logon events to be audited, including the following settings:

- Do not audit
- Audit only success events
- Audit on failure events
- Audit both success and failure events

Set by using the Audit logon events setting in the Local Policies/Audit Policy GPO.

If any of the three audit options are set (audit only success events, audit only failure events, audit both success and failure events), ONTAP audits both success and failure events.

- Audit object access

Specifies the type of object access to be audited, including the following settings:

- Do not audit
- Audit only success events
- Audit on failure events
- Audit both success and failure events

Set by using the Audit object access setting in the Local Policies/Audit Policy GPO.

If any of the three audit options are set (audit only success events, audit only failure events, audit both success and failure events), ONTAP audits both success and failure events.

- Log retention method

Specifies the audit log retention method, including the following settings:

- Overwrite the event log when size of the log file exceeds the maximum log size
- Do not overwrite the event log (clear log manually)

Set by using the Retention method for security log setting in the Event Log GPO.

- Maximum log size

Specifies the maximum size of the audit log.

Set by using the Maximum security log size setting in the Event Log GPO.

To use audit policy and event log GPO settings, auditing must be configured on the CIFS-enabled SVM to which you want to apply these setting. If auditing is not configured on the SVM, the GPO settings will not be applied and will be dropped.

- File system security

Specifies a list of files or directories on which file security is applied through a GPO.

Set by using the File System GPO.

The volume path to which the file system security GPO is configured must exist within the SVM.

- Kerberos policy

- Maximum clock skew

Specifies maximum tolerance in minutes for computer clock synchronization.

Set by using the Maximum tolerance for computer clock synchronization setting in the Account Policies/Kerberos Policy GPO.

- Maximum ticket age

Specifies maximum lifetime in hours for user ticket.

Set by using the Maximum lifetime for user ticket setting in the Account Policies/Kerberos Policy GPO.

- Maximum ticket renew age

Specifies maximum lifetime in days for user ticket renewal.

Set by using the Maximum lifetime for user ticket renewal setting in the Account Policies/Kerberos Policy GPO.

- User rights assignment (privilege rights)

- Take ownership

Specifies the list of users and groups that have the right to take ownership of any securable object.

Set by using the Take ownership of files or other objects setting in the Local Policies/User Rights Assignment GPO.

- Security privilege

Specifies the list of users and groups that can specify auditing options for object access of individual resources, such as files, folders, and Active Directory objects.

Set by using the Manage auditing and security log setting in the Local Policies/User Rights Assignment GPO.

- Change notify privilege (bypass traverse checking)

Specifies the list of users and groups that can traverse directory trees even though the users and groups might not have permissions on the traversed directory.

The same privilege is required for users to receive notifications of changes to files and directories.
Set by using the Bypass traverse checking setting in the Local Policies/User Rights Assignment GPO.

- Registry values

- Signing required setting

Specifies whether required SMB signing is enabled or disabled.

Set by using the Microsoft network server: Digitally sign communications (always) setting in the Security Options GPO.

- Restrict anonymous

Specifies what the restrictions for anonymous users are and includes the following three GPO settings:

- No enumeration of Security Account Manager (SAM) accounts:

This security setting determines what additional permissions are granted for anonymous connections to the computer. This option is displayed as no-enumeration in ONTAP if it is enabled.

Set by using the Network access: Do not allow anonymous enumeration of SAM accounts setting in the Local Policies/Security Options GPO.

- No enumeration of SAM accounts and shares

This security setting determines whether anonymous enumeration of SAM accounts and shares is allowed. This option is displayed as no-enumeration in ONTAP if it is enabled.

Set by using the Network access: Do not allow anonymous enumeration of SAM accounts and shares **setting in the Local Policies/Security Options GPO.**

- Restrict anonymous access to shares and named pipes

This security setting restricts anonymous access to shares and pipes. This option is displayed as no-access in ONTAP if it is enabled.

Set by using the Network access: Restrict anonymous access to Named Pipes and Shares **setting in the Local Policies/Security Options GPO.**

When displaying information about defined and applied group policies, the Resultant restriction for anonymous user output field provides information about the resultant restriction of the three restrict anonymous GPO settings. The possible resultant restrictions are as follows:

- ° no-access

The anonymous user is denied access to the specified shares and named pipes, and cannot use enumeration of SAM accounts and shares. This resultant restriction is seen if the Network access : Restrict anonymous access to Named Pipes and Shares GPO is enabled.

- ° no-enumeration

The anonymous user has access to the specified shares and named pipes, but cannot use enumeration of SAM accounts and shares. This resultant restriction is seen if both of the following conditions are met:

- The Network access: Restrict anonymous access to Named Pipes and Shares GPO is disabled.
- Either the Network access: Do not allow anonymous enumeration of SAM accounts or the Network access: Do not allow anonymous enumeration of SAM accounts and shares GPOs is enabled.

- ° no-restriction

The anonymous user has full access and can use enumeration. This resultant restriction is seen if both of the following conditions are met:

- The Network access: Restrict anonymous access to Named Pipes and Shares GPO is disabled.
- Both the Network access: Do not allow anonymous enumeration of SAM accounts and Network access: Do not allow anonymous enumeration of SAM accounts and shares GPOs are disabled.
 - Restricted Groups

You can configure restricted groups to centrally manage membership of either built-in or user-defined groups. When you apply a restricted group through a group policy, the membership of a CIFS server local group is automatically set to match the membership-list settings defined in the applied group policy.

Set by using the Restricted Groups GPO.

- Central access policy settings

Specifies a list of central access policies. Central access policies and the associated central access policy rules determine access permissions for multiple files on the SVM.

Requirements for using GPOs with your SMB server

To use Group Policy Objects (GPOs) with your SMB server, your system must meet several requirements.

- SMB must be licensed on the cluster.
- A SMB server must be configured and joined to a Windows Active Directory domain.
- The SMB server admin status must be on.
- GPOs must be configured and applied to the Windows Active Directory Organizational Unit (OU) containing the SMB server computer object.
- GPO support must be enabled on the SMB server.

Enable or disable GPO support on a CIFS server

You can enable or disable Group Policy Object (GPO) support on a CIFS server. If you enable GPO support on a CIFS server, the applicable GPOs that are defined on the group policy—the policy that is applied to the organizational unit (OU) that contains the CIFS server computer object—are applied to the CIFS server.

About this task

GPOs cannot be enabled on CIFS servers in workgroup mode.

Steps

1. Perform one of the following actions:

If you want to...	Enter the command...
Enable GPOs	vserver cifs group-policy modify -vserver <i>vserver_name</i> -status enabled
Disable GPOs	vserver cifs group-policy modify -vserver <i>vserver_name</i> -status disabled

2. Verify that GPO support is in the desired state: `vserver cifs group-policy show -vserver +vserver_name_`

Group Policy Status for CIFS servers in workgroup mode is displayed as “disabled”.

Example

The following example enables GPO support on storage virtual machine (SVM) vs1:

```
cluster1::> vserver cifs group-policy modify -vserver vs1 -status enabled

cluster1::> vserver cifs group-policy show -vserver vs1

      Vserver: vs1
Group Policy Status: enabled
```

[Manually updating GPO settings on the CIFS server](#)

[Displaying information about GPO configurations](#)

[How GPOs are updated on the SMB server](#)

[How GPOs are updated on the CIFS server overview](#)

By default, ONTAP retrieves and applies Group Policy Object (GPO) changes every 90 minutes. Security settings are refreshed every 16 hours. If you want to update GPOs to apply new GPO policy settings before ONTAP automatically updates them, you can trigger a manual update on a CIFS server with an ONTAP command.

- By default, all GPOs are verified and updated as needed every 90 minutes.

This interval is configurable and can be set using the Refresh interval and Random offset GPO settings.

ONTAP queries Active Directory for changes to GPOs. If the GPO version numbers recorded in Active

Directory are higher than those on the CIFS server, ONTAP retrieves and applies the new GPOs. If the version numbers are the same, GPOs on the CIFS server are not updated.

- Security Settings GPOs are refreshed every 16 hours.

ONTAP retrieves and applies Security Settings GPOs every 16 hours, whether or not these GPOs have changed.

The 16-hour default value cannot be changed in the current ONTAP version. It is a Windows client default setting.

- All GPOs can be updated manually with an ONTAP command.

This command simulates the Windows `gpupdate.exe `/force`` command.

Related information

[Manually updating GPO settings on the CIFS server](#)

What to do if GPO updates are failing

Under some circumstances, Group Policy Object (GPO) updates from Windows 2012 domain controllers might fail, which leads to nothing being visible under the Central Access Policy Settings section of the output for the `vserver cifs group-policy show-defined` command. You should know how to correct this issue if it occurs.

Underlying cause	Remedy
<p>When ONTAP attempts to connect to the Windows 2012 domain controller to perform the GPO update, the connection might fail with the error <code>error 0xc00000bd (NT STATUS_DUPLICATE_NAME)</code>.</p> <p>This error occurs when the server name used to make the connection is different from the NetBIOS name of the CIFS server. There are various reasons this might occur, including the use of aliases. Additionally, ONTAP pads the NetBIOS name used when connecting to the domain controller to make the name length equal to 15 characters. This can make it appear that the CIFS server name and the NetBIOS name are different.</p>	<ol style="list-style-type: none">1. Disable NetBIOS name checking on the Windows server by adding the following registry key with the value set to 1: <code>"HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\LanmanServer\Parameters\DisableStrictNameChecking"</code> To learn more about this registry key, contact Microsoft Support. Microsoft Support2. Reboot the domain controller.

[Manually updating GPO settings on the CIFS server](#)

If you want to update Group Policy Object (GPO) settings on your CIFS server immediately, you can manually update the settings. You can update only changed settings or you can force an update for all settings, including the settings that were applied previously but have not changed.

Step

1. Perform the appropriate action:

If you want to update...	Enter the command...
Changed GPO settings	vserver cifs group-policy update -vserver vserver_name
All GPO settings	vserver cifs group-policy update -vserver vserver_name -force-reapply -all-settings true

Related information

[How GPOs are updated on the CIFS server](#)

Display information about GPO configurations

You can display information about Group Policy Object (GPO) configurations that are defined in Active Directory and about GPO configurations applied to the CIFS server.

About this task

You can display information about all GPO configurations defined in the Active Directory of the domain to which the CIFS server belongs, or you can display information only about GPO configurations applied to a CIFS server.

Steps

1. Display information about GPO configurations by performing one of the following actions:

If you want to display information about all Group Policy configurations...	Enter the command...
Defined in Active Directory	vserver cifs group-policy show-defined -vserver vserver_name
Applied to a CIFS-enabled storage virtual machine (SVM)	vserver cifs group-policy show-applied -vserver vserver_name

Example

The following example displays the GPO configurations defined in the Active Directory to which the CIFS-enabled SVM named vs1 belongs:

```
cluster1::> vserver cifs group-policy show-defined -vserver vs1

Related information

[Enabling or disabling GPO support on a CIFS server](#)

[Display detailed information about restricted group GPOs](#)

You can display detailed information about restricted groups that are defined as Group Policy Objects (GPOs) in Active Directory and that are applied to the CIFS server.

About this task

By default, the following information is displayed:

- Group policy name
- Group policy version

- **Link**

Specifies the level in which the group policy is configured. Possible output values include the following:

- Local when the group policy is configured in ONTAP
- Site when the group policy is configured at the site level in the domain controller
- Domain when the group policy is configured at the domain level in the domain controller
- OrganizationalUnit when the group policy is configured at the Organizational Unit (OU) level in the domain controller
- RSOP for the resultant set of policies derived from all the group policies defined at various levels

- Restricted group name
- The users and groups who belong to and who do not belong to the restricted group
- The list of groups to which the restricted group is added

A group can be a member of groups other than the groups listed here.

Step

1. Display information about all restricted group GPOs by performing one of the following actions:

If you want to display information about all restricted group GPOs...	Enter the command...
Defined in Active Directory	<code>vserver cifs group-policy restricted-group show-defined -vserver vserver_name</code>
Applied to a CIFS server	<code>vserver cifs group-policy restricted-group show-applied -vserver vserver_name</code>

Example

The following example displays information about restricted group GPOs defined in the Active Directory domain to which the CIFS-enabled SVM named vs1 belongs:

```
cluster1::> vserver cifs group-policy restricted-group show-defined  
-vserver vs1  
  
Vserver: vs1  
-----  
  
    Group Policy Name: gpo1  
        Version: 16  
            Link: OrganizationalUnit  
    Group Name: group1  
        Members: user1  
        MemberOf: EXAMPLE\group9  
  
    Group Policy Name: Resultant Set of Policy  
        Version: 0  
            Link: RSOP  
    Group Name: group1  
        Members: user1  
        MemberOf: EXAMPLE\group9
```

The following example displays information about restricted groups GPOs applied to the CIFS-enabled SVM vs1:

```
cluster1::> vserver cifs group-policy restricted-group show-applied  
-vserver vs1  
  
Vserver: vs1  
-----

Displaying information about GPO configurations

Display information about central access policies

You can display detailed information about the central access policies that are defined in Active Directory. You can also display information about the central access policies that are applied to the CIFS server through group policy objects (GPOs).

About this task

By default, the following information is displayed:

- SVM name
- Name of the central access policy
- SID
- Description
- Creation time
- Modification time
- Member rules

CIFS servers in workgroup mode are not displayed because they do not support GPOs.

Step

1. Display information about central access policies by performing one of the following actions:

If you want to display information about all central access policies...	Enter the command...
Defined in Active Directory	<code>vserver cifs group-policy central-access-policy show-defined -vserver <i>vserver_name</i></code>
Applied to a CIFS server	<code>vserver cifs group-policy central-access-policy show-applied -vserver <i>vserver_name</i></code>

Example

The following example displays information for all the central access policies that are defined in Active Directory:

```

cluster1::> vserver cifs group-policy central-access-policy show-defined

Vserver      Name          SID
-----
-----
vs1          p1           S-1-17-3386172923-1132988875-3044489393-
3993546205
    Description: policy #1
    Creation Time: Tue Oct 22 09:34:13 2013
    Modification Time: Wed Oct 23 08:59:15 2013
    Member Rules: r1

vs1          p2           S-1-17-1885229282-1100162114-134354072-
822349040
    Description: policy #2
    Creation Time: Tue Oct 22 10:28:20 2013
    Modification Time: Thu Oct 31 10:25:32 2013
    Member Rules: r1
                      r2

```

The following example displays information for all the central access policies that are applied to the storage virtual machines (SVMs) on the cluster:

```

cluster1::> vserver cifs group-policy central-access-policy show-applied

Vserver      Name          SID
-----
-----
vs1          p1           S-1-17-3386172923-1132988875-3044489393-
3993546205
    Description: policy #1
    Creation Time: Tue Oct 22 09:34:13 2013
    Modification Time: Wed Oct 23 08:59:15 2013

Display information about central access policy rules

You can display detailed information about central access policy rules that are associated with central access policies defined in Active Directory. You can also display information about central access policies rules that are applied to the CIFS server through central access policy GPOs (group policy objects).

About this task

You can display detailed information about defined and applied central access policy rules. By default, the following information is displayed:

- Vserver name
- Name of the central access rule
- Description
- Creation time
- Modification time
- Current permissions
- Proposed permissions
- Target resources

Table 1. Step

If you want to display information about all central access policy rules associated with central access policies...	Enter the command...
Defined in Active Directory	<code>vserver cifs group-policy central-access-rule show-defined -vserver vserver_name</code>
Applied to a CIFS server	<code>vserver cifs group-policy central-access-rule show-applied -vserver vserver_name</code>

Example

The following example displays information for all central access policy rules associated with central access policies defined in Active Directory:

```

cluster1::> vserver cifs group-policy central-access-rule show-defined

Vserver      Name
-----
vs1          r1
    Description: rule #1
    Creation Time: Tue Oct 22 09:33:48 2013
    Modification Time: Tue Oct 22 09:33:48 2013
    Current Permissions: O:SYG:SYD:AR(A;;FA;;;WD)
    Proposed Permissions: O:SYG:SYD:(A;;FA;;;OW) (A;;FA;;;BA) (A;;FA;;;SY)

vs1          r2
    Description: rule #2
    Creation Time: Tue Oct 22 10:27:57 2013
    Modification Time: Tue Oct 22 10:27:57 2013
    Current Permissions: O:SYG:SYD:AR(A;;FA;;;WD)
    Proposed Permissions: O:SYG:SYD:(A;;FA;;;OW) (A;;FA;;;BA) (A;;FA;;;SY)

```

The following example displays information for all central access policy rules associated with central access policies applied to storage virtual machines (SVMs) on the cluster:

```

cluster1::> vserver cifs group-policy central-access-rule show-applied

Vserver      Name
-----
vs1          r1
    Description: rule #1

Commands for managing SMB servers computer account passwords

You need to know the commands for changing, resetting, and disabling passwords, and for configuring automatic update schedules. You can also configure a schedule on the SMB server to update it automatically.

If you want to...	Use this command...
Change or reset the domain account password and you know the password	vserver cifs domain password change
Reset the domain account password and you do not know the password	vserver cifs domain password reset
Configure SMB servers for automatic computer account password changes	vserver cifs domain password schedule modify -vserver vserver_name -is-schedule-enabled true
Disable automatic computer account password changes on SMB servers	vserver cifs domain password schedule modify -vserver vs1 -is-schedule-enabled false

See the man page for each command for more information.

Manage domain controller connections

Display information about discovered servers

You can display information related to discovered LDAP servers and domain controllers on your CIFS server.

Step

1. To display information related to discovered servers, enter the following command: `vserver cifs domain discovered-servers show`

Example

The following example shows discovered servers for SVM vs1:

```
cluster1::> vserver cifs domain discovered-servers show
```

Node: node1

Vserver: vs1

Domain Name	Type	Preference	DC-Name	DC-Address	Status
example.com	MS-LDAP	adequate	DC-1	1.1.3.4	OK
example.com	MS-LDAP	adequate	DC-2	1.1.3.5	OK
example.com	MS-DC	adequate	DC-1	1.1.3.4	OK
example.com	MS-DC	adequate	DC-2	1.1.3.5	OK

Related information

[Resetting and rediscovering servers](#)

[Stopping or starting the CIFS server](#)

Reset and rediscover servers

Resetting and rediscovering servers on your CIFS server allows the CIFS server to discard stored information about LDAP servers and domain controllers. After discarding server information, the CIFS server reacquires current information about these external servers. This can be useful when the connected servers are not responding appropriately.

Steps

1. Enter the following command: `vserver cifs domain discovered-servers reset-servers -vserver vserver_name`
2. Display information about the newly rediscovered servers: `vserver cifs domain discovered-servers show -vserver vserver_name`

Example

The following example resets and redisCOVERS servers for storage virtual machine (SVM, formerly known as Vserver) vs1:

```

cluster1::> vserver cifs domain discovered-servers reset-servers -vserver
vs1

cluster1::> vserver cifs domain discovered-servers show

Node: node1
Vserver: vs1

Domain Name      Type       Preference DC-Name      DC-Address    Status
-----          -----      -----      -----          -----        -----
example.com      MS-LDAP   adequate   DC-1          1.1.3.4      OK
example.com      MS-LDAP   adequate   DC-2          1.1.3.5      OK
example.com      MS-DC     adequate   DC-1          1.1.3.4      OK
example.com      MS-DC     adequate   DC-2          1.1.3.5      OK

```

[Displaying information about discovered servers](#)

[Stopping or starting the CIFS server](#)

[Manage domain controller discovery](#)

Beginning with ONTAP 9.3, you can modify the default process by which domain controllers (DCs) are discovered. This enables you to limit discovery to your site or to a pool of preferred DCs, which can lead to performance improvements depending on the environment.

About this task

By default, the dynamic discovery process discovers all available DCs, including any preferred DCs, all DCs in the local site, and all remote DCs. This configuration can lead to latency in authentication and accessing shares in certain environments. If you have already determined the pool of DCs that you want to use, or if the remote DCs are inadequate or inaccessible, you can change the discovery method.

In ONTAP 9.3 and later releases, the `discovery-mode` parameter of the `cifs domain discovered-servers` command enables you to select one of the following discovery options:

- All DCs in the domain are discovered.
- Only DCs in the local site are discovered.

The `default-site` parameter for the SMB server must be defined to use this mode.

- Server discovery is not performed, the SMB server configuration depends only on preferred DCs.

To use this mode, you must first define the preferred DCs for the SMB server.

Step

1. Specify the desired discovery option: `vserver cifs domain discovered-servers discovery-mode modify -vserver vserver_name -mode {all|site|none}`

Options for the mode parameter:

◦ all

Discover all available DCs (default).

◦ site

Limit DC discovery to your site.

◦ none

Use only preferred DCs and not perform discovery.

Add preferred domain controllers

ONTAP automatically discovers domain controllers through DNS. Optionally, you can add one or more domain controllers to the list of preferred domain controllers for a specific domain.

About this task

If a preferred domain controller list already exists for the specified domain, the new list is merged with the existing list.

Step

1. To add to the list of preferred domain controllers, enter the following command:

```
vserver cifs domain preferred-dc add -vserver vserver_name -domain domain_name  
-preferred-dc IP_address, ...+
```

`-vserver vserver_name` specifies the storage virtual machine (SVM) name.

`-domain domain_name` specifies the fully qualified Active Directory name of the domain to which the specified domain controllers belong.

`-preferred-dc IP_address,...` specifies one or more IP addresses of the preferred domain controllers, as a comma-delimited list, in order of preference.

Example

The following command adds domain controllers 172.17.102.25 and 172.17.102.24 to the list of preferred domain controllers that the SMB server on SVM vs1 uses to manage external access to the `cifs.lab.example.com` domain.

```
cluster1::> vserver cifs domain preferred-dc add -vserver vs1 -domain  
cifs.lab.example.com -preferred-dc 172.17.102.25,172.17.102.24
```

[Commands for managing preferred domain controllers](#)

Commands for managing preferred domain controllers

You need to know the commands for adding, displaying, and removing preferred domain controllers.

If you want to...	Use this command...
Add a preferred domain controller	vserver cifs domain preferred-dc add
Display preferred domain controllers	vserver cifs domain preferred-dc show
Remove a preferred domain controller	vserver cifs domain preferred-dc remove

See the man page for each command for more information.

Related information

[Adding preferred domain controllers](#)

Enable SMB2 connections to domain controllers

Beginning with ONTAP 9.1, you can enable SMB version 2.0 to connect to a domain controller. Doing so is necessary if you have disabled SMB 1.0 on domain controllers. Beginning with ONTAP 9.2, SMB2 is enabled by default.

About this task

The `smb2-enabled-for-dc-connections` command option enables the system default for the release of ONTAP you are using. The system default for ONTAP 9.1 is enabled for SMB 1.0 and disabled for SMB 2.0. The system default for ONTAP 9.2 is enabled for SMB 1.0 and enabled for SMB 2.0. If the domain controller cannot negotiate SMB 2.0 initially, it uses SMB 1.0.

SMB 1.0 can be disabled from ONTAP to a domain controller. In ONTAP 9.1, if SMB 1.0 has been disabled, SMB 2.0 must be enabled in order to communicate with a domain controller.

If `-smb1-enabled-for-dc-connections` is set to `false` while `-smb1-enabled` is set to `true`, ONTAP denies SMB 1.0 connections as the client, but continues to accept inbound SMB 1.0 connections as the server. See the topic, *Enabling and disabling SMB versions* in this guide.

Steps

1. Before changing SMB security settings, verify which SMB versions are enabled: `vserver cifs security show`
2. Scroll down the list to see the SMB versions.
3. Perform the appropriate command, using the `smb2-enabled-for-dc-connections` option.

If you want SMB2 to be...	Enter the command...
Enabled	<code>vserver cifs security modify -vserver vserver_name -smb2-enabled-for-dc-connections true</code>

If you want SMB2 to be...	Enter the command...
Disabled	vserver cifs security modify -vserver vserver_name -smb2-enabled-for-dc -connections false

Related information

[Supported SMB versions and functionality](#)

Enable encrypted connections to domain controllers

Beginning with ONTAP 9.8, you can specify that connections to domain controllers be encrypted.

About this task

ONTAP requires encryption for domain controller (DC) communications when the `-encryption-required-for-dc-connection` option is set to `true`; the default is `false`. When the option is set, only the SMB3 protocol will be used for ONTAP-DC connections, because encryption is only supported by SMB3.

When encrypted DC communications are required, the `-smb2-enabled-for-dc-connections` option is ignored, because ONTAP only negotiates SMB3 connections. If a DC doesn't support SMB3 and encryption, ONTAP will not connect with it.

Step

1. Enable encrypted communication with the DC: `vserver cifs security modify -vserver
svm_name -encryption-required-for-dc-connection true`

Use null sessions to access storage in non-Kerberos environments

Use null sessions to access storage in non-Kerberos environments overview

Null session access provides permissions for network resources, such as storage system data, and to client-based services running under the local system. A null session occurs when a client process uses the “system” account to access a network resource. Null session configuration is specific to non-Kerberos authentication.

How the storage system provides null session access

Because null session shares do not require authentication, clients that require null session access must have their IP addresses mapped on the storage system.

By default, unmapped null session clients can access certain ONTAP system services, such as share enumeration, but they are restricted from accessing any storage system data.

ONTAP supports Windows RestrictAnonymous registry setting values with the `-restrict-anonymous` option. This enables you to control the extent to which unmapped null users can view or access system resources. For example, you can disable share enumeration and access to the IPC\$ share (the hidden named pipe share). The `vserver cifs options modify` and `vserver cifs options show` man pages provide more information about the `-restrict-anonymous` option.

Unless otherwise configured, a client running a local process that requests storage system access through a null session is a member only of nonrestrictive groups, such as “everyone”. To limit null session access to selected storage system resources, you might want to create a group to which all null session clients belong; creating this group enables you to restrict storage system access and to set storage system resource permissions that apply specifically to null session clients.

ONTAP provides a mapping syntax in the `vserver name-mapping` command set to specify the IP address of clients allowed access to storage system resources using a null user session. After you create a group for null users, you can specify access restrictions for storage system resources and resource permissions that apply only to null sessions. Null user is identified as anonymous logon. Null users do not have access to any home directory.

Any null user accessing the storage system from a mapped IP address is granted mapped user permissions. Consider appropriate precautions to prevent unauthorized access to storage systems mapped with null users. For maximum protection, place the storage system and all clients requiring null user storage system access on a separate network, to eliminate the possibility of IP address “spoofing”.

Related information

[Configuring access restrictions for anonymous users](#)

Grant null users access to file system shares

You can allow access to your storage system resources by null session clients by assigning a group to be used by null session clients and recording the IP addresses of null session clients to add to the storage system’s list of clients allowed to access data using null sessions.

Steps

1. Use the `vserver name-mapping create` command to map the null user to any valid windows user, with an IP qualifier.

The following command maps the null user to user1 with a valid host name google.com:

```
vserver name-mapping create -direction win-unix -position 1 -pattern  
"ANONYMOUS LOGON" -replacement user1 -hostname google.com
```

The following command maps the null user to user1 with a valid IP address 10.238.2.54/32:

```
vserver name-mapping create -direction win-unix -position 2 -pattern  
"ANONYMOUS LOGON" -replacement user1 -address 10.238.2.54/32
```

2. Use the vserver name-mapping show command to confirm the name mapping.

```
vserver name-mapping show

Vserver:    vs1
Direction:  win-unix
Position   Hostname          IP Address/Mask
-----   -----
1           -                10.72.40.83/32      Pattern: anonymous logon
                                         Replacement: user1
```

3. Use the vserver cifs options modify -win-name-for-null-user command to assign Windows membership to the null user.

This option is applicable only when there is a valid name mapping for the null user.

```
vserver cifs options modify -win-name-for-null-user user1
```

4. Use the vserver cifs options show command to confirm the mapping of the null user to the Windows user or group.

```
vserver cifs options show

Vserver :vs1

Map Null User to Windows User of Group: user1
```

Manage NetBIOS aliases for SMB servers

Manage NetBIOS aliases for SMB servers overview

NetBIOS aliases are alternative names for your SMB server that SMB clients can use when connecting to the SMB server. Configuring NetBIOS aliases for a SMB server can be useful when you are consolidating data from other file servers to the SMB server and want the SMB server to respond to the original file servers' names.

You can specify a list of NetBIOS aliases when you create the SMB server or at any time after you create the SMB server. You can add or remove NetBIOS aliases from the list at any time. You can connect to the SMB server using any of the names in the NetBIOS alias list.

Related information

[Displaying information about NetBIOS over TCP connections](#)

Add a list of NetBIOS aliases to the SMB server

If you want SMB clients to connect to the SMB server by using an alias, you can create a list of NetBIOS aliases, or you can add NetBIOS aliases to an existing list of NetBIOS aliases.

About this task

- The NetBIOS alias name can be 15 up to characters in length.
- You can configure up to 200 NetBIOS aliases on the SMB server.
- The following characters are not allowed:

@ # * () = + [] | ; : " , < > \ / ?

Steps

1. Add the NetBIOS aliases:

```
vserver cifs add-netbios-aliases -vserver vserver_name -netbios-aliases  
NetBIOS_alias,...
```

```
vserver cifs add-netbios-aliases -vserver vs1 -netbios-aliases  
alias_1,alias_2,alias_3
```

- You can specify one or more NetBIOS aliases by using a comma-delimited list.
- The specified NetBIOS aliases are added to the existing list.
- A new list of NetBIOS aliases is created if the list is currently empty.

2. Verify that the NetBIOS aliases were added correctly: `vserver cifs show -vserver vserver_name -display-netbios-aliases`

```
vserver cifs show -vserver vs1 -display-netbios-aliases
```

```
Vserver: vs1  
  
Server Name: CIFS_SERVER  
NetBIOS Aliases: ALIAS_1, ALIAS_2, ALIAS_3
```

Related information

[Removing NetBIOS aliases from the NetBIOS alias list](#)

[Displaying the list of NetBIOS aliases on CIFS servers](#)

Remove NetBIOS aliases from the NetBIOS alias list

If you do not need specific NetBIOS aliases for a CIFS server, you can remove those NetBIOS aliases from the list. You can also remove all NetBIOS aliases from the list.

About this task

You can remove more than one NetBIOS alias by using a comma-delimited list. You can remove all of the NetBIOS aliases on a CIFS server by specifying – as the value for the –netbios-aliases parameter.

Steps

1. Perform one of the following actions:

If you want to remove...	Enter...
Specific NetBIOS aliases from the list	vserver cifs remove-netbios-aliases -vserver <u>vserver_name</u> -netbios -aliases <u>NetBIOS_alias</u> ,...
All NetBIOS aliases from the list	vserver cifs remove-netbios-aliases -vserver <u>vserver_name</u> -netbios-aliases -

```
vserver cifs remove-netbios-aliases -vserver vs1 -netbios-aliases alias_1
```

2. Verify that the specified NetBIOS aliases were removed: `vserver cifs show -vserver vserver_name -display-netbios-aliases`

```
vserver cifs show -vserver vs1 -display-netbios-aliases
```

```
Vserver: vs1
```

```
Server Name: CIFS_SERVER
NetBIOS Aliases: ALIAS_2, ALIAS_3
```

Display the list of NetBIOS aliases on CIFS servers

You can display the list of NetBIOS aliases. This can be useful when you want to determine the list of names over which SMB clients can make connections to the CIFS server.

Step

1. Perform one of the following actions:

If you want to display information about...	Enter...
A CIFS server's NetBIOS aliases	vserver cifs show -display-netbios -aliases
The list of NetBIOS aliases as part of the detailed CIFS server information	vserver cifs show -instance

The following example displays information about a CIFS server's NetBIOS aliases:

```
vserver cifs show -display-netbios-aliases
```

```
Vserver: vs1
```

```
    Server Name: CIFS_SERVER  
    NetBIOS Aliases: ALIAS_1, ALIAS_2, ALIAS_3
```

The following example displays the list of NetBIOS aliases as part of the detailed CIFS server information:

```
vserver cifs show -instance
```

```
        Vserver: vs1  
        CIFS Server NetBIOS Name: CIFS_SERVER  
        NetBIOS Domain/Workgroup Name: EXAMPLE  
        Fully Qualified Domain Name: EXAMPLE.COM  
Default Site Used by LIFs Without Site Membership:  
        Authentication Style: domain  
        CIFS Server Administrative Status: up  
        CIFS Server Description:  
        List of NetBIOS Aliases: ALIAS_1, ALIAS_2,  
ALIAS_3
```

See the man page for the commands for more information.

Related information

[Adding a list of NetBIOS aliases to the CIFS server](#)

[Commands for managing CIFS servers](#)

Determine whether SMB clients are connected using NetBIOS aliases

You can determine whether SMB clients are connected using NetBIOS aliases, and if so, which NetBIOS alias is used to make the connection. This can be useful when troubleshooting connection issues.

About this task

You must use the `-instance` parameter to display the NetBIOS alias (if any) associated with an SMB connection. If the CIFS server name or an IP address is used to make the SMB connection, the output for the NetBIOS Name field is `-` (hyphen).

Step

1. Perform the desired action:

If you want to display NetBIOS information for...	Enter...
SMB connections	<code>vserver cifs session show -instance</code>

If you want to display NetBIOS information for...	Enter...
Connections using a specified NetBIOS alias:	vserver cifs session show -instance -netbios-name <i>netbios_name</i>

The following example displays information about the NetBIOS alias used to make the SMB connection with session ID 1:

```
vserver cifs session show -session-id 1 -instance
```

```

        Node: node1
        Vserver: vs1
        Session ID: 1
        Connection ID: 127834
        Incoming Data LIF IP Address: 10.1.1.25
                                Workstation: 10.2.2.50
        Authentication Mechanism: NTLMv2
                                Windows User: EXAMPLE\user1
                                UNIX User: user1
        Open Shares: 2
        Open Files: 2
        Open Other: 0
        Connected Time: 1d 1h 10m 5s
        Idle Time: 22s
        Protocol Version: SMB3
        Continuously Available: No
        Is Session Signed: true
        User Authenticated as: domain-user
                                NetBIOS Name: ALIAS1
        SMB Encryption Status: Unencrypted
    
```

Manage miscellaneous SMB server tasks

Stop or start the CIFS server

You can stop the CIFS server on a SVM, which can be useful when performing tasks while users are not accessing data over SMB shares. You can restart SMB access by starting the CIFS server. By stopping the CIFS server, you can also modify the protocols allowed on the storage virtual machine (SVM).

Steps

1. Perform one of the following actions:

If you want to...	Enter the command...
Stop the CIFS server	vserver cifs stop -vserver vserver_name [-foreground {true false}]
Start the CIFS server	vserver cifs start -vserver vserver_name [-foreground {true false}]

-foreground specifies whether the command should execute in the foreground or background. If you do not enter this parameter, it is set to true, and the command is executed in the foreground.

- Verify that the CIFS server administrative status is correct by using the vserver cifs show command.

Example

The following commands start the CIFS server on SVM vs1:

```
cluster1::> vserver start -vserver vs1

cluster1::> vserver cifs show -vserver vs1

          Vserver: vs1
          CIFS Server NetBIOS Name: VS1
          NetBIOS Domain/Workgroup Name: DOMAIN
          Fully Qualified Domain Name: DOMAIN.LOCAL
Default Site Used by LIFs Without Site Membership:
          Authentication Style: domain
          CIFS Server Administrative Status: up
```

[Resetting and rediscovering servers](#)

Move CIFS servers to different OUs

The CIFS server create-process uses the default organizational unit (OU) CN=Computers during setup unless you specify a different OU. You can move CIFS servers to different OUs after setup.

Steps

- On the Windows server, open the **Active Directory Users and Computers** tree.
- Locate the Active Directory object for the storage virtual machine (SVM).
- Right-click the object and select **Move**.
- Select the OU that you want to associate with the SVM

Results

The SVM object is placed in the selected OU.

Modify the dynamic DNS domain on the SVM before moving the SMB server

If you want the Active Directory-integrated DNS server to dynamically register the SMB server's DNS records in DNS when you move the SMB server to another domain, you must modify dynamic DNS (DDNS) on the storage virtual machine (SVM) before moving the SMB server.

Before you begin

DNS name services must be modified on the SVM to use the DNS domain that contains the service location records for the new domain that will contain the SMB server computer account. If you are using secure DDNS, you must use Active Directory-integrated DNS name servers.

About this task

Although DDNS (if configured on the SVM) automatically adds the DNS records for data LIFs to the new domain, the DNS records for the original domain are not automatically deleted from the original DNS server. You must delete them manually.

To complete your DDNS modifications before moving the SMB server, see the following topic:

[Configure dynamic DNS services](#)

Join a SVM to an Active Directory domain

You can join a storage virtual machine (SVM) to an Active Directory domain without deleting the existing SMB server by modifying the domain using the `vserver cifs modify` command. You can rejoin the current domain or join a new one.

Before you begin

- The SVM must already have a DNS configuration.
- The DNS configuration for the SVM must be able to serve the target domain.

The DNS servers must contain the service location records (SRV) for the domain LDAP and domain controller servers.

About this task

- The administrative status of the CIFS server must be set to "down" to proceed with Active Directory domain modification.
- If the command completes successfully, the administrative status is automatically set to "up".
- When joining a domain, this command might take several minutes to complete.

Steps

1. Join the SVM to the CIFS server domain: `vserver cifs modify -vserver vserver_name -domain domain_name -status-admin down`

For more information, see the man page for the `vserver cifs modify` command. If you need to reconfigure DNS for the new domain, see the man page for the `vserver dns modify` command.

In order to create an Active Directory machine account for the SMB server, you must supply the name and password of a Windows account with sufficient privileges to add computers to the `ou= example ou` container within the `example.com` domain.

Beginning with ONTAP 9.7, your AD administrator can provide you with a URI to a keytab file as an alternative to providing you with a name and password to a privileged Windows account. When you receive the URI, include it in the `-keytab-uri` parameter with the `vserver cifs` commands.

2. Verify that the CIFS server is in the desired Active Directory domain: `vserver cifs show`

Example

In the following example, the SMB server “CIFSSERVER1” on SVM vs1 joins the `example.com` domain using keytab authentication:

```
cluster1::> vserver cifs modify -vserver vs1 -domain example.com -status  
-admin down -keytab-uri http://admin.example.com/ontap1.keytab  
  
cluster1::> vserver cifs show  
  
      Server          Status    Domain/Workgroup  Authentication  
Vserver  Name        Admin       Name            Style  
-----  -----  
vs1     CIFSSERVER1  up         EXAMPLE        domain
```

Display information about NetBIOS over TCP connections

You can display information about NetBIOS over TCP (NBT) connections. This can be useful when troubleshooting NetBIOS-related issues.

Step

1. Use the `vserver cifs nbtstat` command to display information about NetBIOS over TCP connections.

NetBIOS name service (NBNS) over IPv6 is not supported.

Example

The following example shows the NetBIOS name service information displayed for “cluster1”:

```

cluster1::> vserver cifs nbtstat

    Vserver: vs1
    Node:    cluster1-01
    Interfaces:
        10.10.10.32
        10.10.10.33
    Servers:
        17.17.1.2 (active )
    NBT Scope:
        [ ]
    NBT Mode:
        [h]
    NBT Name      NetBIOS Suffix      State   Time Left   Type
    -----  -----  -----  -----  -----
    CLUSTER_1    00                  wins     57
    CLUSTER_1    20                  wins     57

    Vserver: vs1
    Node:    cluster1-02
    Interfaces:
        10.10.10.35
    Servers:
        17.17.1.2 (active )
    CLUSTER_1      00                  wins     58
    CLUSTER_1      20                  wins     58
    4 entries were displayed.

```

Commands for managing SMB servers

You need to know the commands for creating, displaying, modifying, stopping, starting, and deleting SMB servers. There are also commands to reset and rediscover servers, change or reset machine account passwords, schedule changes for machine account passwords, and add or remove NetBIOS aliases.

If you want to...	Use this command...
Create an SMB server	vserver cifs create
Display information about an SMB server	vserver cifs show
Modify an SMB server	vserver cifs modify
Move an SMB server to another domain	vserver cifs modify

Stop an SMB server	vserver cifs stop
Start an SMB server	vserver cifs start
Delete an SMB server	vserver cifs delete
Reset and rediscover servers for the SMB server	vserver cifs domain discovered-servers reset-servers
Change the SMB server's machine account password	vserver cifs domain password change
Reset the SMB server's machine account password	vserver cifs domain password change
Schedule automatic password changes for the SMB server's machine account	vserver cifs domain password schedule modify
Add NetBIOS aliases for the SMB server	vserver cifs add-netbios-aliases
Remove NetBIOS aliases for the SMB server	vserver cifs remove-netbios-aliases

See the man page for each command for more information.

[What happens to local users and groups when deleting SMB servers](#)

Enable the NetBios name service

Beginning with ONTAP 9, the NetBios name service (NBNS, sometimes called Windows Internet Name Service or WINS) is disabled by default. Previously, CIFS-enabled storage virtual machines (SVMs) sent name registration broadcasts regardless of whether WINS was enabled on a network. To limit such broadcasts to configurations where NBNS is required, you must enable NBNS explicitly for new CIFS servers.

Before you begin

- If you are already using NBNS and you upgrade to ONTAP 9, it is not necessary to complete this task. NBNS will continue to work as before.
- NBNS is enabled over UDP (port 137).
- NBNS over IPv6 is not supported.

Steps

1. Set the privilege level to advanced.

```
set -privilege advanced
```

2. Enable NBNS on a CIFS server.

```
vserver cifs options modify -vserver <vserver name> -is-nbns-enabled true
```

3. Return to the admin privilege level.

```
set -privilege admin
```

Use IPv6 for SMB access and SMB services

Requirements for using IPv6

Before you can use IPv6 on your SMB server, you need to know which versions of ONTAP and SMB support it and what the license requirements are.

ONTAP license requirements

No special license is required for IPv6 when SMB is licensed.

SMB protocol version requirements

- For SVMs, ONTAP supports IPv6 on all versions of the SMB protocol.

NetBIOS name service (NBNS) over IPv6 is not supported.

Support for IPv6 with SMB access and CIFS services

If you want to use IPv6 on your CIFS server, you need to be aware of how ONTAP supports IPv6 for SMB access and network communication for CIFS services.

Windows client and server support

ONTAP provides support for Windows servers and clients that support IPv6. The following describes Microsoft Windows client and server IPv6 support:

- Windows XP and Windows 2003 support IPv6 for SMB file sharing.

These versions provide limited support for IPv6.

- Windows 7, Windows 8, Windows Server 2008, Windows Server 2012 and later support IPv6 for both SMB file sharing and Active Directory services, including DNS, LDAP, CLDAP, and Kerberos services.

If IPv6 addresses are configured, Windows 7 and Windows Server 2008 and later releases use IPv6 by default for Active Directory services. Both NTLM and Kerberos authentication over IPv6 connections are supported.

All Windows clients supported by ONTAP can connect to SMB shares by using IPv6 addresses.

For the latest information about which Windows clients ONTAP supports, see the Interoperability Matrix.

Interoperability Matrix

NT domains are not supported for IPv6.

Additional CIFS services support

In addition to IPv6 support for SMB file shares and Active Directory services, ONTAP provides IPv6 support for the following:

- Client-side services, including offline folders, roaming profiles, folder redirection, and Previous Versions
- Server-side services, including Dynamic home directories (Home Directory feature), symlinks and Widelinks, BranchCache, ODX copy offload, automatic node referrals, and Previous Versions
- File access management services, including the use of Windows local users and groups for access control and rights management, setting file permissions and audit policies using the CLI, security tracing, file locks management, and monitoring SMB activity
- NAS multiprotocol auditing
- FPolicy
- Continuously available shares, Witness protocol, and Remote VSS (used with Hyper-V over SMB configurations)

Name service and authentication service support

Communication with the following name services are supported with IPv6:

- Domain controllers
- DNS servers
- LDAP servers
- KDC servers
- NIS servers

How CIFS servers use IPv6 to connect to external servers

To create a configuration that meets your requirements, you must be aware of how CIFS servers use IPv6 when making connections to external servers.

- Source address selection

If an attempt is made to connect to an external server, the source address selected must be of the same type as the destination address. For example, if connecting to an IPv6 address, the storage virtual machine (SVM) hosting the CIFS server must have a data LIF or management LIF that has an IPv6 address to use as the source address. Similarly, if connecting to an IPv4 address, the SVM must have a data LIF or management LIF that has an IPv4 address to use as the source address.

- For servers dynamically discovered using DNS, server discovery is performed as follows:
 - If IPv6 is disabled on the cluster, only IPv4 servers addresses are discovered.
 - If IPv6 is enabled on the cluster, both IPv4 and IPv6 server addresses are discovered. Either type might be used depending upon the suitability of the server to which the address belongs and the

availability of IPv6 or IPv4 data or management LIFs.

Dynamic server discovery is used for discovering Domain Controllers and their associated services, such as LSA, NETLOGON, Kerberos, and LDAP.

- DNS server connectivity

Whether the SVM uses IPv6 when connecting to a DNS server depends on the DNS name services configuration. If DNS services are configured to use IPv6 addresses, connections are made by using IPv6. If desired, the DNS name services configuration can use IPv4 addresses so that connections to DNS servers continue to use IPv4 addresses. Combinations of IPv4 and IPv6 addresses can be specified when configuring DNS name services.

- LDAP server connectivity

Whether the SVM uses IPv6 when connecting to an LDAP server depends on the LDAP client configuration. If the LDAP client is configured to use IPv6 addresses, connections are made by using IPv6. If desired, the LDAP client configuration can use IPv4 addresses so that connections to LDAP servers continue to use IPv4 addresses. Combinations of IPv4 and IPv6 addresses can be specified when configuring the LDAP client configuration.

The LDAP client configuration is used when configuring LDAP for UNIX user, group, and netgroup name services.

- NIS server connectivity

Whether the SVM uses IPv6 when connecting to a NIS server depends on the NIS name services configuration. If NIS services are configured to use IPv6 addresses, connections are made by using IPv6. If desired, the NIS name services configuration can use IPv4 addresses so that connections to NIS servers continue to use IPv4 addresses. Combinations of IPv4 and IPv6 addresses can be specified when configuring NIS name services.

NIS name services are used for storing and managing UNIX user, group, netgroup, and host name objects.

Related information

[Enabling IPv6 for SMB \(cluster administrators only\)](#)

[Monitoring and displaying information about IPv6 SMB sessions](#)

[Enable IPv6 for SMB \(cluster administrators only\)](#)

IPv6 networks are not enabled during cluster setup. A cluster administrator must enable IPv6 after cluster setup is complete to use IPv6 for SMB. When the cluster administrator enables IPv6, it is enabled for the entire cluster.

Step

1. Enable IPv6: `network options ipv6 modify -enabled true`

For more information about enabling IPv6 on the cluster and configuring IPv6 LIFs, see the *Network Management Guide*.

IPv6 is enabled. IPv6 data LIFs for SMB access can be configured.

Related information

[Monitoring and displaying information about IPv6 SMB sessions](#)

Network management

Disable IPv6 for SMB

Even though IPv6 is enabled on the cluster using a network option, you cannot disable IPv6 for SMB by using the same command. Instead, ONTAP disables IPv6 when the cluster administrator disables the last IPv6-enabled interface on the cluster. You should communicate with the cluster administrator about management of your IPv6 enabled interfaces.

For more information about disabling IPv6 on the cluster, see the *Network Management Guide*.

Related information

[Network management](#)

Monitor and display information about IPv6 SMB sessions

You can monitor and display information about SMB sessions that are connected using IPv6 networks. This information is useful in determining which clients are connecting using IPv6 as well as other useful information about IPv6 SMB sessions.

Step

1. Perform the desired action:

If you want to determine whether...	Enter the command...
SMB sessions to a storage virtual machine (SVM) are connected using IPv6	<code>vserver cifs session show -vserver vserver_name -instance</code>
IPv6 is used for SMB sessions through a specified LIF address	<code>vserver cifs session show -vserver vserver_name -lif-address <i>LIF_IP_address</i> -instance</code> <i>LIF_IP_address</i> is the data LIF's IPv6 address.

Set up file access using SMB

Configure security styles

How security styles affect data access

What the security styles and their effects are

There are four different security styles: UNIX, NTFS, mixed, and unified. Each security style has a different effect on how permissions are handled for data. You must understand the different effects to ensure that you select the appropriate security style for your

purposes.

It is important to understand that security styles do not determine what client types can or cannot access data. Security styles only determine the type of permissions ONTAP uses to control data access and what client type can modify these permissions.

For example, if a volume uses UNIX security style, SMB clients can still access data (provided that they properly authenticate and authorize) due to the multiprotocol nature of ONTAP. However, ONTAP uses UNIX permissions that only UNIX clients can modify using native tools.

Security style	Clients that can modify permissions	Permissions that clients can use	Resulting effective security style	Clients that can access files
UNIX	NFS	NFSv3 mode bits	UNIX	NFS and SMB
		NFSv4.x ACLs	UNIX	
NTFS	SMB	NTFS ACLs	NTFS	
Mixed	NFS or SMB	NFSv3 mode bits	UNIX	
		NFSv4.x ACLs	UNIX	
NTFS ACLs	NTFS	Unified	NFS or SMB	
NFSv3 mode bits	UNIX			
NFSv4.1 ACLs	UNIX	NTFS ACLs	NTFS	
Unified (For infinite volumes only, in ONTAP 9.4 and earlier releases)	NFS or SMB	NFSv3 mode bits	Unix	NTFS ACLs
		NFSv4.1 ACLs		

FlexVol volumes support UNIX, NTFS, and mixed security styles. When the security style is mixed or unified, the effective permissions depend on the client type that last modified the permissions because users set the security style on an individual basis. If the last client that modified permissions was an NFSv3 client, the permissions are UNIX NFSv3 mode bits. If the last client was an NFSv4 client, the permissions are NFSv4 ACLs. If the last client was an SMB client, the permissions are Windows NTFS ACLs.

The unified security style is only available with infinite volumes, which are no longer supported in ONTAP 9.5 and later releases. For more information, see [FlexGroup volumes management overview](#).

Beginning with ONTAP 9.2, the `show-effective-permissions` parameter to the `vserver security file-directory` command enables you to display effective permissions granted to a Windows or UNIX user on the specified file or folder path. In addition, the optional parameter `-share-name` enables you to display the effective share permission.

ONTAP initially sets some default file permissions. By default, the effective security style on all data in UNIX, mixed, and unified security style volumes is UNIX and the effective permissions type is UNIX mode bits (0755 unless specified otherwise) until configured by a client as allowed by the default security style. By default, the effective security style on all data in NTFS security style volumes is NTFS and has an ACL allowing full control to everyone.

2021-12-09, BURT 1443623

Where and when to set security styles

Security styles can be set on FlexVol volumes (both root or data volumes) and qtrees. Security styles can be set manually at the time of creation, inherited automatically, or changed at a later time.

Decide which security style to use on SVMs

To help you decide which security style to use on a volume, you should consider two factors. The primary factor is the type of administrator that manages the file system. The secondary factor is the type of user or service that accesses the data on the volume.

When you configure the security style on a volume, you should consider the needs of your environment to ensure that you select the best security style and avoid issues with managing permissions. The following considerations can help you decide:

Security style	Choose if...
UNIX	<ul style="list-style-type: none">The file system is managed by a UNIX administrator.The majority of users are NFS clients.An application accessing the data uses a UNIX user as the service account.
NTFS	<ul style="list-style-type: none">The file system is managed by a Windows administrator.The majority of users are SMB clients.An application accessing the data uses a Windows user as the service account.
Mixed	The file system is managed by both UNIX and Windows administrators and users consist of both NFS and SMB clients.

How security style inheritance works

If you do not specify the security style when creating a new FlexVol volume or a qtree, it inherits its security style in different ways.

Security styles are inherited in the following manner:

- A FlexVol volume inherits the security style of the root volume of its containing SVM.
- A qtree inherits the security style of its containing FlexVol volume.
- A file or directory inherits the security style of its containing FlexVol volume or qtree.

How ONTAP preserves UNIX permissions

When files in a FlexVol volume that currently have UNIX permissions are edited and saved by Windows applications, ONTAP can preserve the UNIX permissions.

When applications on Windows clients edit and save files, they read the security properties of the file, create a new temporary file, apply those properties to the temporary file, and then give the temporary file the original file name.

When Windows clients perform a query for the security properties, they receive a constructed ACL that exactly represents the UNIX permissions. The sole purpose of this constructed ACL is to preserve the file's UNIX permissions as files are updated by Windows applications to ensure that the resulting files have the same UNIX permissions. ONTAP does not set any NTFS ACLs using the constructed ACL.

Manage UNIX permissions using the Windows Security tab

If you want to manipulate UNIX permissions of files or folders in mixed security-style volumes or qtrees on SVMs, you can use the Security tab on Windows clients. Alternatively, you can use applications that can query and set Windows ACLs.

- Modifying UNIX permissions

You can use the Windows Security tab to view and change UNIX permissions for a mixed security-style volume or qtree. If you use the main Windows Security tab to change UNIX permissions, you must first remove the existing ACE you want to edit (this sets the mode bits to 0) before you make your changes. Alternatively, you can use the Advanced editor to change permissions.

If mode permissions are used, you can directly change the mode permissions for the listed UID, GID, and others (everyone else with an account on the computer). For example, if the displayed UID has r-x permissions, you can change the UID permissions to rwx.

- Changing UNIX permissions to NTFS permissions

You can use the Windows Security tab to replace UNIX security objects with Windows security objects on a mixed security-style volume or qtree where the files and folders have a UNIX effective security style.

You must first remove all listed UNIX permission entries before you can replace them with the desired Windows User and Group objects. You can then configure NTFS-based ACLs on the Windows User and Group objects. By removing all UNIX security objects and adding only Windows Users and Groups to a file or folder in a mixed security-style volume or qtree, you change the effective security style on the file or folder from UNIX to NTFS.

When changing permissions on a folder, the default Windows behavior is to propagate these changes to all subfolders and files. Therefore, you must change the propagation choice to the desired setting if you do not want to propagate a change in security style to all child folders, subfolders, and files.

Configure security styles on SVM root volumes

You configure the storage virtual machine (SVM) root volume security style to determine the type of permissions used for data on the root volume of the SVM.

Steps

1. Use the `vserver create` command with the `-rootvolume-security-style` parameter to define the security style.

The possible options for the root volume security style are `unix`, `ntfs`, or `mixed`.

2. Display and verify the configuration, including the root volume security style of the SVM you created:

```
vserver show -vserver vserver_name
```

Configure security styles on FlexVol volumes

You configure the FlexVol volume security style to determine the type of permissions used for data on FlexVol volumes of the storage virtual machine (SVM).

Steps

1. Perform one of the following actions:

If the FlexVol volume...	Use the command...
Does not yet exist	<code>volume create</code> and include the <code>-security-style</code> parameter to specify the security style.
Already exists	<code>volume modify</code> and include the <code>-security-style</code> parameter to specify the security style.

The possible options for the FlexVol volume security style are `unix`, `ntfs`, or `mixed`.

If you do not specify a security style when creating a FlexVol volume, the volume inherits the security style of the root volume.

For more information about the `volume create` or `volume modify` commands, see [Logical storage management](#).

2. To display the configuration, including the security style of the FlexVol volume you created, enter the following command: `volume show -volume volume_name -instance`

```
= Configure security styles on qtrees
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

You configure the qtree volume security style to determine the type of permissions used for data on qtrees.

Steps

1. Perform one of the following actions:

If the qtree...	Use the command...
Does not exist yet	volume qtree create and include the <code>-security-style</code> parameter to specify the security style.
Already exists	volume qtree modify and include the <code>-security-style</code> parameter to specify the security style.

The possible options for the qtree security style are `unix`, `ntfs`, or `mixed`.

If you do not specify a security style when creating a qtree, the default security style is `mixed`.

For more information about the `volume qtree create` or `volume qtree modify` commands, see [Logical storage management](#).

2. To display the configuration, including the security style of the qtree you created, enter the following command: `volume qtree show -qtree qtree_name -instance`

= Create and manage data volumes in NAS namespaces

= Create and manage data volumes in NAS namespaces overview

```
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

To manage file access in a NAS environment, you must manage data volumes and junction points on your storage virtual machine (SVM). This includes planning your namespace architecture, creating volumes with or without junction points, mounting or unmounting volumes, and displaying information about data volumes and NFS server or CIFS server namespaces.

= Create data volumes with specified junction points

```
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

You can specify the junction point when you create a data volume. The resultant

volume is automatically mounted at the junction point and is immediately available to configure for NAS access.

Before you begin

The aggregate in which you want to create the volume must already exist.

The following characters cannot be used in the junction path: * # " > < | ? \

In addition, the junction path length cannot be more than 255 characters.

Steps

1. Create the volume with a junction point: `volume create -vserver vserver_name -volume volume_name -aggregate aggregate_name -size {integer[KB|MB|GB|TB|PB]} -security-style {ntfs|unix|mixed} -junction-path junction_path`

The junction path must start with the root (/) and can contain both directories and junctioned volumes. The junction path does not need to contain the name of the volume. Junction paths are independent of the volume name.

Specifying a volume security style is optional. If you do not specify a security style, ONTAP creates the volume with the same security style that is applied to the root volume of the storage virtual machine (SVM). However, the root volume's security style might not be the security style you want applied to the data volume you create. The recommendation is to specify the security style when you create the volume to minimize difficult-to-troubleshoot file-access issues.

The junction path is case insensitive; /ENG is the same as /eng. If you create a CIFS share, Windows treats the junction path as if it is case sensitive. For example, if the junction is /ENG, the path of a CIFS share must start with /ENG, not /eng.

There are many optional parameters that you can use to customize a data volume. To learn more about them, see the man pages for the `volume create` command.

2. Verify that the volume was created with the desired junction point: `volume show -vserver vserver_name -volume volume_name -junction`

Example

The following example creates a volume named “home4” located on SVM vs1 that has a junction path /eng/home:

```
cluster1::> volume create -vserver vs1 -volume home4 -aggregate aggr1  
-size 1g -junction-path /eng/home  
[Job 1642] Job succeeded: Successful

cluster1::> volume show -vserver vs1 -volume home4 -junction  
Junction Junction  
Vserver Volume Active Junction Path Path Source  
-----  
vs1     home4   true    /eng/home      RW_volume
```

= Create data volumes without specifying junction points
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can create a data volume without specifying a junction point. The resultant volume is not automatically mounted, and is not available to configure for NAS access. You must mount the volume before you can configure SMB shares or NFS exports for that volume.

Before you begin

The aggregate in which you want to create the volume must already exist.

Steps

1. Create the volume without a junction point by using the following command: `volume create -vserver vserver_name -volume volume_name -aggregate aggregate_name -size {integer[KB|MB|GB|TB|PB]} -security-style {ntfs|unix|mixed}`

Specifying a volume security style is optional. If you do not specify a security style, ONTAP creates the volume with the same security style that is applied to the root volume of the storage virtual machine (SVM). However, the root volume's security style might not be the security style you want applied to the data volume. The recommendation is to specify the security style when you create the volume to minimize difficult-to-troubleshoot file-access issues.

There are many optional parameters that you can use to customize a data volume. To learn more about them, see the man pages for the `volume create` command.

2. Verify that the volume was created without a junction point: `volume show -vserver vserver_name -volume volume_name -junction`

Example

The following example creates a volume named "sales" located on SVM vs1 that is not mounted at a junction point:

```
cluster1::> volume create -vserver vs1 -volume sales -aggregate aggr3  
-size 20GB  
[Job 3406] Job succeeded: Successful  
  
cluster1::> volume show -vserver vs1 -junction  
          Junction          Junction  
Vserver   Volume   Active   Junction Path   Path Source  
-----  
vs1       data      true    /data           RW_volume  
vs1       home4     true    /eng/home       RW_volume  
vs1       vs1_root   -       /               -  
vs1       sales      -       -               -
```

= Mount or unmount existing volumes in the NAS namespace
:icons: font

```
:relative_path: ./smb-admin/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/
```

A volume must be mounted on the NAS namespace before you can configure NAS client access to data contained in the storage virtual machine (SVM) volumes. You can mount a volume to a junction point if it is not currently mounted. You can also unmount volumes.

About this task

If you unmount and offline a volume, all data within the junction point, including data in volumes with junction points contained within the unmounted volume's namespace, are inaccessible to NAS clients.

To discontinue NAS client access to a volume, it is not sufficient to simply unmount the volume. You must offline the volume, or take other steps to ensure that client-side file handle caches are invalidated. For more information, see the following Knowledge Base article:[https://kb.netapp.com/Advice_and_Troubleshooting/Data_Storage_Software/ONTA_P_OS/NFSv3_clients_still_have_access_to_a_volume_after_being_removed_from_the_namespace_in_ONTAP\[NFSv3 clients still have access to a volume after being removed from the namespace in ONTAP\]](https://kb.netapp.com/Advice_and_Troubleshooting/Data_Storage_Software/ONTA_P_OS/NFSv3_clients_still_have_access_to_a_volume_after_being_removed_from_the_namespace_in_ONTAP[NFSv3 clients still have access to a volume after being removed from the namespace in ONTAP])

When you unmount and offline a volume, data within the volume is not lost. Additionally, existing volume export policies and SMB shares created on the volume or on directories and junction points within the unmounted volume are retained. If you remount the unmounted volume, NAS clients can access the data contained within the volume using existing export policies and SMB shares.

Steps

1. Perform the desired action:

If you want to...	Enter the commands...
Mount a volume	<code>volume mount -vserver svm_name -volume volume_name -junction-path junction_path</code>
Unmount a volume	<code>volume unmount -vserver svm_name -volume volume_name volume offline -vserver svm_name -volume volume_name</code>

2. Verify that the volume is in the desired mount state: `volume show -vserver vserver_name
-volume volume_name -fields state,junction-path,junction-active`

Examples

The following example mounts a volume named "sales" located on SVM vs1 to the junction point /sales:

```

cluster1::> volume mount -vserver vs1 -volume sales -junction-path
/sales

cluster1::> volume show -vserver vs1 state,junction-path,junction-
active

vserver    volume     state      junction-path      junction-active
-----  -----
vs1        data       online     /data             true
vs1        home4     online     /eng/home         true
vs1        sales      online     /sales            true

```

The following example unmounts and offline a volume named “data” located on SVM vs1:

```

cluster1::> volume unmount -vserver vs1 -volume data
cluster1::> volume offline -vserver vs1 -volume data

cluster1::> volume show -vserver vs1 -fields state,junction-
path,junction-active

vserver    volume     state      junction-path      junction-active
-----  -----
vs1        data       offline    -                 -
vs1        home4     online     /eng/home         true
vs1        sales      online     /sales            true

```

= Display volume mount and junction point information

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can display information about mounted volumes for storage virtual machines (SVMs) and the junction points to which the volumes are mounted. You can also determine which volumes are not mounted to a junction point. You can use this information to understand and manage your SVM namespace.

Steps

1. Perform the desired action:

If you want to display...	Enter the command...
Summary information about mounted and unmounted volumes on the SVM	volume show -vserver vserver_name -junction

If you want to display...	Enter the command...
Detailed information about mounted and unmounted volumes on the SVM	volume show -vserver vserver_name -volume volume_name -instance
Specific information about mounted and unmounted volumes on the SVM	<p>a. If necessary, you can display valid fields for the -fields parameter by using the following command: <code>volume show -fields ?</code></p> <p>b. Display the desired information by using the -fields parameter: <code>volume show -vserver vserver_name -fields fieldname,...</code></p>

Examples

The following example displays a summary of mounted and unmounted volumes on SVM vs1:

```
cluster1::> volume show -vserver vs1 -junction
                Junction          Junction
Vserver   Volume     Active   Junction Path    Path Source
-----  -----
vs1       data       true    /data           RW_volume
vs1       home4      true    /eng/home       RW_volume
vs1       vs1_root   -       /                 -
vs1       sales      true    /sales          RW_volume
```

The following example displays information about specified fields for volumes located on SVM vs2:

```

cluster1::> volume show -vserver vs2 -fields
vserver,volume,aggregate,size,state,type,security-style,junction-
path,junction-parent,node
vserver volume    aggregate size state   type security-style junction-
path junction-parent node
-----
----- ----- ----- ----- -----

= Configure name mappings

= Configure name mappings overview

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

ONTAP uses name mapping to map CIFS identities to UNIX identities, Kerberos identities to UNIX identities, and UNIX identities to CIFS identities. It needs this information to obtain user credentials and provide proper file access regardless of whether they are connecting from an NFS client or a CIFS client.

There are two exceptions where you do not have to use name mapping:

- You configure a pure UNIX environment and do not plan to use CIFS access or NTFS security style on volumes.
- You configure the default user to be used instead.

In this scenario, name mapping is not required because instead of mapping every individual client credential all client credentials are mapped to the same default user.

Note that you can use name mapping only for users, not for groups.

However, you can map a group of individual users to a specific user. For example, you can map all AD users that start or end with the word SALES to a specific UNIX user and to the user's UID.

= How name mapping works

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

When ONTAP has to map credentials for a user, it first checks the local name mapping database and LDAP server for an existing mapping. Whether it checks one or both and in which order is determined by the name service configuration of the SVM.

- For Windows to UNIX mapping

If no mapping is found, ONTAP checks whether the lowercase Windows user name is a valid user name in the UNIX domain. If this does not work, it uses the default UNIX user provided that it is configured. If the default UNIX user is not configured and ONTAP cannot obtain a mapping this way either, mapping fails and an error is returned.

- For UNIX to Windows mapping

If no mapping is found, ONTAP tries to find a Windows account that matches the UNIX name in the SMB domain. If this does not work, it uses the default SMB user, provided that it is configured. If the default CIFS user is not configured and ONTAP cannot obtain a mapping this way either, mapping fails and an error is returned.

Machine accounts are mapped to the specified default UNIX user by default. If no default UNIX user is specified, machine account mappings fail.

- Beginning with ONTAP 9.5, you can map machine accounts to users other than the default UNIX user.
- In ONTAP 9.4 and earlier, you cannot map machine accounts to other users.

Even if name mappings for machine accounts are defined, the mappings are ignored.

= Multidomain searches for UNIX user to Windows user name mappings

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

ONTAP supports multidomain searches when mapping UNIX users to Windows users. All discovered trusted domains are searched for matches to the replacement pattern until a matching result is returned. Alternatively, you can configure a list of preferred trusted domains, which is used instead of the discovered trusted domain list and is searched in order until a matching result is returned.

== How domain trusts affect UNIX user to Windows user name mapping searches

To understand how multidomain user name mapping works, you must understand how domain trusts work with ONTAP. Active Directory trust relationships with the CIFS server's home domain can be a bidirectional trust or can be one of two types of unidirectional trusts, either an inbound trust or an outbound trust. The home domain is the domain to which the CIFS server on the SVM belongs.

- *Bidirectional trust*

With bidirectional trusts, both domains trust each other. If the CIFS server's home domain has a bidirectional trust with another domain, the home domain can authenticate and authorize a user belonging to the trusted domain and vice versa.

UNIX user to Windows user name mapping searches can be performed only on domains with bidirectional trusts between the home domain and the other domain.

- *Outbound trust*

With an outbound trust, the home domain trusts the other domain. In this case, the home domain can authenticate and authorize a user belonging to the outbound trusted domain.

A domain with an outbound trust with the home domain is *not* searched when performing UNIX user to Windows user name mapping searches.

- *Inbound trust*

With an inbound trust, the other domain trusts the CIFS server's home domain. In this case, the home domain cannot authenticate or authorize a user belonging to the inbound trusted domain.

A domain with an inbound trust with the home domain is *not* searched when performing UNIX user to Windows user name mapping searches.

== How wildcards (*) are used to configure multidomain searches for name mapping

Multidomain name mapping searches are facilitated by the use of wildcards in the domain section of the Windows user name. The following table illustrates how to use wildcards in the domain part of a name mapping entry to enable multidomain searches:

Pattern	Replacement	Result
root	*\\administrator	The UNIX user "root" is mapped to the user named "administrator". All trusted domains are searched in order until the first matching user named "administrator" is found.
*	**	Valid UNIX users are mapped to the corresponding Windows users. All trusted domains are searched in order until the first matching user with that name is found.

The pattern ** is only valid for name mapping from UNIX to Windows, not the other way around.

== How multidomain name searches are performed

You can choose one of two methods for determining the list of trusted domains used for multidomain name searches:

- Use the automatically discovered bidirectional trust list compiled by ONTAP
- Use the preferred trusted domain list that you compile

If a UNIX user is mapped to a Windows user with a wildcard used for the domain section of the user name, the Windows user is looked up in all the trusted domains as follows:

- If a preferred trusted-domain list is configured, the mapped Windows user is looked up in this search list only, in order.
- If a preferred list of trusted domains is not configured, then the Windows user is looked up in all the bidirectional trusted domains of the home domain.
- If there are no bidirectionally trusted domains for the home domain, the user is looked up in the home domain.

If a UNIX user is mapped to a Windows user without a domain section in the user name, the Windows user is looked up in the home domain.

= Name mapping conversion rules

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

An ONTAP system keeps a set of conversion rules for each SVM. Each rule consists of two pieces: a *pattern* and a *replacement*. Conversions start at the beginning of the appropriate list and perform a substitution based on the first matching rule. The pattern is a UNIX-style regular expression. The replacement is a string containing escape sequences representing subexpressions from the pattern, as in the UNIX sed program.

= Create a name mapping

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can use the vserver name-mapping create command to create a name mapping. You use name mappings to enable Windows users to access UNIX security style volumes and the reverse.

About this task

For each SVM, ONTAP supports up to 12,500 name mappings for each direction.

Step

1. Create a name mapping: `vserver name-mapping create -vserver vserver_name -direction {krb-unix|win-unix|unix-win} -position integer -pattern text -replacement text`

The `-pattern` and `-replacement` statements can be formulated as regular expressions. You can also use the `-replacement` statement to explicitly deny a mapping to the user by using the null replacement string " " (the space character). See the `vserver name-mapping create` man page for details.

When Windows-to-UNIX mappings are created, any SMB clients that have open connections to the ONTAP system at the time the new mappings are created must log out and log back in to see the new mappings.

Examples

The following command creates a name mapping on the SVM named vs1. The mapping is a mapping from UNIX to Windows at position 1 in the priority list. The mapping maps the UNIX user johnd to the Windows user ENG\JohnDoe.

```
vs1::> vserver name-mapping create -vserver vs1 -direction unix-win  
-position 1 -pattern johnd  
-replacement "ENG\\JohnDoe"
```

The following command creates another name mapping on the SVM named vs1. The mapping is a mapping from Windows to UNIX at position 1 in the priority list. Here the pattern and replacement include regular expressions. The mapping maps every CIFS user in the domain ENG to users in the LDAP domain associated with the SVM.

```
vs1::> vserver name-mapping create -vserver vs1 -direction win-unix  
-position 1 -pattern "ENG\\(.+)"  
-replacement "\1"
```

The following command creates another name mapping on the SVM named vs1. Here the pattern includes "\$" as an element in the Windows user name that must be escaped. The mapping maps the windows user ENG\ john\$\ops to UNIX user john_ops.

```
vs1::> vserver name-mapping create -direction win-unix -position 1  
-pattern ENG\\john\\$ops  
-replacement john_ops
```

= Configure the default user
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can configure a default user to use if all other mapping attempts fail for a user, or if you do not want to map individual users between UNIX and Windows. Alternatively, if you want authentication of non-mapped users to fail, you should not configure a default user.

About this task

For CIFS authentication, if you do not want to map each Windows user to an individual UNIX user, you can instead specify a default UNIX user.

For NFS authentication, if you do not want to map each UNIX user to an individual Windows user, you can instead specify a default Windows user.

Steps

1. Perform one of the following actions:

If you want to...	Enter the following command...
Configure the default UNIX user	<code>vserver cifs options modify -default-unix-user <i>user_name</i></code>
Configure the default Windows user	<code>vserver nfs modify -default-win-user <i>user_name</i></code>

= Commands for managing name mappings

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

There are specific ONTAP commands for managing name mappings.

If you want to...	Use this command...
Create a name mapping	<code>vserver name-mapping create</code>
Insert a name mapping at a specific position	<code>vserver name-mapping insert</code>
Display name mappings	<code>vserver name-mapping show</code>
Exchange the position of two name mappings	<code>vserver name-mapping swap</code>
 A swap is not allowed when name-mapping is configured with an ip-qualifier entry.	
Modify a name mapping	<code>vserver name-mapping modify</code>
Delete a name mapping	<code>vserver name-mapping delete</code>
Validate the correct name mapping	<code>vserver security file-directory show-effective-permissions -vserver vs1 -win-user-name user1 -path / -share-name sh1</code>

See the man page for each command for more information.

= Configure multidomain name-mapping searches

= Enable or disable multidomain name mapping searches

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

With multidomain name mapping searches, you can use a wild card (*) in the domain portion of a Windows name when configuring UNIX user to Windows user name mapping. Using a wild card (*) in the domain portion of the name enables ONTAP to search all domains that have a bidirectional trust with the domain that contains the CIFS server's computer account.

About this task

As an alternative to searching all bidirectionally trusted domains, you can configure a list of preferred trusted domains. When a list of preferred trusted domains is configured, ONTAP uses the preferred trusted domain list instead of the discovered bidirectionally trusted domains to perform multidomain name mapping searches.

- Multidomain name mapping searches are enabled by default.
- This option is available at the advanced privilege level.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Perform one of the following actions:

If you want multidomain name mapping searches to be...	Enter the command...
Enabled	<code>vserver cifs options modify -vserver <i>vserver_name</i> -is-trusted-domain-enum -search-enabled true</code>
Disabled	<code>vserver cifs options modify -vserver <i>vserver_name</i> -is-trusted-domain-enum -search-enabled false</code>

3. Return to the admin privilege level: `set -privilege admin`

= Reset and rediscover trusted domains

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can force the rediscovery of all the trusted domains. This can be useful when the

trusted domain servers are not responding appropriately or the trust relationships have changed. Only domains with a bidirectional trust with the home domain, which is the domain containing the CIFS server's computer account, are discovered.

Step

1. Reset and rediscover trusted domains by using the `vserver cifs domain trusts rediscover` command.

```
vserver cifs domain trusts rediscover -vserver vs1
```

Related information

[Displaying information about discovered trusted domains](#)

= Display information about discovered trusted domains

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can display information about the discovered trusted domains for the CIFS server's home domain, which is the domain containing the CIFS server's computer account. This can be useful when you want to know which trusted domains are discovered and how they are ordered within the discovered trusted-domain list.

About this task

Only the domains with bidirectional trusts with the home domain are discovered. Since the home domain's domain controller (DC) returns the list of trusted domains in an order determined by the DC, the order of the domains within the list cannot be predicted. By displaying the list of trusted domains, you can determine the search order for multidomain name mapping searches.

The displayed trusted domain information is grouped by node and storage virtual machine (SVM).

Step

1. Display information about discovered trusted domains by using the `vserver cifs domain trusts show` command.

```
vserver cifs domain trusts show -vserver vs1
```

Node: node1	
Vserver: vs1	
Home Domain	Trusted Domain
-----	-----
EXAMPLE.COM	CIFS1.EXAMPLE.COM, CIFS2.EXAMPLE.COM EXAMPLE.COM
Node: node2	
Vserver: vs1	
Home Domain	Trusted Domain
-----	-----
EXAMPLE.COM	CIFS1.EXAMPLE.COM, CIFS2.EXAMPLE.COM EXAMPLE.COM

[Resetting and rediscovering trusted domains](#)

= Add, remove, or replace trusted domains in preferred trusted domain lists

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

You can add or remove trusted domains from the preferred trusted domain list for the SMB server or you can modify the current list. If you configure a preferred trusted domain list, this list is used instead of the discovered bidirectional trusted domains when performing multidomain name mapping searches.

About this task

- If you are adding trusted domains to an existing list, the new list is merged with the existing list with the new entries placed at the end. The trusted domains are searched in the order they appear in the trusted domain list.
- If you are removing trusted domains from the existing list and do not specify a list, the entire trusted domain list for the specified storage virtual machine (SVM) is removed.
- If you modify the existing list of trusted domains, the new list overwrites the existing list.

 You should enter only bidirectionally trusted domains in the preferred trusted domain list. Even though you can enter outbound or inbound trust domains into the preferred domain list, they are not used when performing multidomain name mapping searches. ONTAP skips the entry for the unidirectional domain and moves on to the next bidirectional trusted domain in the list.

Step

1. Perform one of the following actions:

If you want to do the following with the list of preferred trusted domains...	Use the command...
Add trusted domains to the list	vserver cifs domain name-mapping-search add -vserver <u>vserver_name_-trusted-domains FQDN</u> , ...
Remove trusted domains from the list	vserver cifs domain name-mapping-search remove -vserver <u>vserver_name_-trusted-domains FQDN</u> , ...]
Modify the existing list	vserver cifs domain name-mapping-search modify -vserver <u>vserver_name_-trusted-domains FQDN</u> , ...

Examples

The following command adds two trusted domains (cifs1.example.com and cifs2.example.com) to the preferred trusted domain list used by SVM vs1:

```
cluster1::> vserver cifs domain name-mapping-search add -vserver vs1
-trusted-domains cifs1.example.com, cifs2.example.com
```

The following command removes two trusted domains from the list used by SVM vs1:

```
cluster1::> vserver cifs domain name-mapping-search remove -vserver vs1
-trusted-domains cifs1.example.com, cifs2.example.com
```

The following command modifies the trusted domain list used by SVM vs1. The new list replaces the original list:

```
cluster1::> vserver cifs domain name-mapping-search modify -vserver vs1
-trusted-domains cifs3.example.com
```

[Adding, removing, or replacing trusted domains in preferred trusted domain lists](#)

= Create and configure SMB shares

= Create and configure SMB shares overview

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Before users and applications can access data on the CIFS server over SMB, you must create and configure SMB shares, which is a named access point in a volume. You can customize shares by specifying share parameters and share properties. You can modify an existing share at any time.

When you create an SMB share, ONTAP creates a default ACL for the share with Full Control permissions for Everyone.

SMB shares are tied to the CIFS server on the storage virtual machine (SVM). SMB shares are deleted if either the SVM is deleted or the CIFS server with which it is associated is deleted from the SVM. If you re-create the CIFS server on the SVM, you must re-create the SMB shares.

Related information

[Managing file access using SMB](#)

SMB configuration for Microsoft Hyper-V and SQL Server

Configuring character mapping for SMB file name translation on volumes

= What the default administrative shares are

```
:icons: font  
:relative_path: ./smb-admin/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

When you create a CIFS server on your storage virtual machine (SVM), three default administrative shares are automatically created. You should understand what those default shares are and how they are used.

ONTAP creates the following default administrative shares when you create the CIFS server:

- ipc\$
- admin\$
- c\$

Because shares that end with the \$ character are hidden shares, the default administrative shares are not visible from My Computer, but you can view them by using Shared Folders.

== How the ipc\$ and admin\$ default shares are used

The ipc\$ and admin\$ shares are used by ONTAP and cannot be used by Windows administrators to access data residing on the SVM.

- ipc\$ share

The ipc\$ share is a resource that shares the named pipes that are essential for communication between programs. The ipc\$ share is used during remote administration of a computer and when viewing a computer's shared resources. You cannot change the share settings, share properties, or ACLs of the ipc\$ share. You also cannot rename or delete the ipc\$ share.

- admin\$ share

The admin\$ share is used during remote administration of the SVM. The path of this resource is always the path to the SVM root. You cannot change the share settings, share properties, or ACLs for the admin\$ share. You also cannot rename or delete the admin\$ share.

== How the c\$ default share is used

The c\$ share is an administrative share that the cluster or SVM administrator can use to access and manage the SVM root volume.

The following are characteristics of the c\$ share:

- The path for this share is always the path to the SVM root volume and cannot be modified.
- The default ACL for the c\$ share is Administrator / Full Control.

This user is the BUILTIN\administrator. By default, the BUILTIN\administrator can map to the share and view, create, modify, or delete files and folders in the mapped root directory. Caution should be exercised when managing files and folders in this directory.

- You can change the c\$ share's ACL.
- You can change the c\$ share settings and share properties.
- You cannot delete the c\$ share.
- The SVM administrator can access the rest of the SVM namespace from the mapped c\$ share by crossing the namespace junctions.
- The c\$ share can be accessed by using the Microsoft Management Console.

= SMB share naming requirements

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You should keep the ONTAP share naming requirements in mind when creating SMB shares on your SMB server.

Share naming conventions for ONTAP are the same as for Windows and include the following requirements:

- The name of each share must be unique for the SMB server.
- Share names are not case-sensitive.
- The maximum share name length is 80 characters.
- Unicode share names are supported.
- Share names ending with the \$ character are hidden shares.
- The ADMIN\$, IPC\$, and c\$ administrative shares are automatically created on every CIFS server and are reserved share names.
- You cannot use the share name ONTAP_ADMIN\$ when creating a share.
- Share names containing spaces are supported:
 - You cannot use a space as the first character or as the last character in a share name.
 - You must enclose share names containing a space in quotation marks.

Single quotation marks are considered part of the share name and cannot be used in place of quotation marks.

- The following special characters are supported when you name SMB shares:

! @ # % & ' _ - . ~ () { }

- The following special characters are not supported when you name SMB shares:

" / \ : ; | < > , ? * =

= Directory case-sensitivity requirements when creating shares in a multiprotocol environment

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you create shares in an SVM where the 8.3 naming scheme is used to distinguish between directory names where there are only case differences between the names, you must use the 8.3 name in the share path to ensure that the client connects to the desired directory path.

In the following example, two directories named “testdir” and “TESTDIR” were created on a Linux client. The junction path of the volume containing the directories is /home. The first output is from a Linux client and the second output is from an SMB client.

```
ls -l
drwxrwxr-x 2 user1 group1    4096 Apr 17 11:23 testdir
drwxrwxr-x 2 user1 group1    4096 Apr 17 11:24 TESTDIR
```

```
dir

Directory of Z:\

04/17/2015  11:23 AM      <DIR>          testdir
04/17/2015  11:24 AM      <DIR>          TESTDI~1
```

When you create a share to the second directory, you must use the 8.3 name in the share path. In this example, the share path to the first directory is /home/testdir and the share path to the second directory is /home/TESTDI~1.

= Use SMB share properties

= Use SMB share properties overview

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can customize the properties of SMB shares.

The available share properties are as follows:

Share properties	Description
oplocks	This property specifies that the share uses opportunistic locks, also known as client-side caching.
browsable	This property allows Windows clients to browse the share.
showsnapshot	This property specifies that Snapshot copies can be viewed and traversed by clients.

Share properties	Description
changenotify	This property specifies that the share supports Change Notify requests. For shares on an SVM, this is a default initial property.
attributecache	This property enables the file attribute caching on the SMB share to provide faster access of attributes. The default is to disable attribute caching. This property should be enabled only if there are clients connecting to shares over SMB 1.0. This share property is not applicable if clients are connecting to shares over SMB 2.x or SMB 3.0.
continuously-available	This property permits SMB clients that support it to open files in a persistent manner. Files opened this way are protected from disruptive events, such as failover and giveback.
branchcache	This property specifies that the share allows clients to request BranchCache hashes on the files within this share. This option is useful only if you specify "per-share" as the operating mode in the CIFS BranchCache configuration.
access-based-enumeration	This property specifies that <i>Access Based Enumeration</i> (ABE) is enabled on this share. ABE-filtered shared folders are visible to a user based on that individual user's access rights, preventing the display of folders or other shared resources that the user does not have rights to access.
namespace-caching	This property specifies that the SMB clients connecting to this share can cache the directory enumeration results returned by the CIFS servers, which can provide better performance. By default, SMB 1 clients do not cache directory enumeration results. Because SMB 2 and SMB 3 clients cache directory enumeration results by default, specifying this share property provides performance benefits only to SMB 1 client connections.
encrypt-data	This property specifies that SMB encryption must be used when accessing this share. SMB clients that do not support encryption when accessing SMB data will not be able to access this share.

= Add or remove share properties on an existing SMB share

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

You can customize an existing SMB share by adding or removing share properties. This can be useful if you want to change the share configuration to meet changing requirements in your environment.

Before you begin

The share whose properties you want to modify must exist.

About this task

Guidelines for adding share properties:

- You can add one or more share properties by using a comma-delimited list.
- Any share properties that you have previously specified remain in effect.

Newly added properties are appended to the existing list of share properties.

- If you specify a new value for share properties that are already applied to the share, the newly specified value replaces the original value.
- You cannot remove share properties by using the `vserver cifs share properties add` command.

You can use the `vserver cifs share properties remove` command to remove share properties.

Guidelines for removing share properties:

- You can remove one or more share properties by using a comma-delimited list.
- Any share properties that you have previously specified but do not remove remain in effect.

Steps

1. Enter the appropriate command:

If you want to...	Enter the command...
Add share properties	<code>vserver cifs share properties add -vserver _vserver_name_ -share-name _share_name_ -share-properties _properties_,...</code>
Remove share properties	<code>vserver cifs share properties remove -vserver _vserver_name_ -share-name _share_name_ -share-properties _properties_,...</code>

2. Verify the share property settings: `vserver cifs share show -vserver vserver_name -share-name share_name`

Examples

The following command adds the `showsnapshot` share property to a share named “share1” on SVM vs1:

```

cluster1::> vserver cifs share properties add -vserver vs1 -share-name
share1 -share-properties showsnapshot

cluster1::> vserver cifs share show -vserver vs1
Vserver      Share     Path      Properties      Comment      ACL
-----      -----      -----      -----      -----
vs1          share1   /share1   oplocks        -           Everyone / Full
Control
                                browsable
                                changenotify
                                showsnapshot

```

The following command removes the browsable share property from a share named “share2” on SVM vs1:

```

cluster1::> vserver cifs share properties remove -vserver vs1 -share
-name share2 -share-properties browsable

cluster1::> vserver cifs share show -vserver vs1
Vserver      Share     Path      Properties      Comment      ACL
-----      -----      -----      -----      -----
vs1          share2   /share2   oplocks        -           Everyone / Full
Control
                                changenotify

```

[Commands for managing SMB shares](#)

= Optimize SMB user access with the force-group share setting

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

When you create a share from the ONTAP command line to data with UNIX effective security, you can specify that all files created by SMB users in that share belong to the same group, known as the **force-group**, which must be a predefined group in the UNIX group database. Using a force-group makes it easier to ensure that files can be accessed by SMB users belonging to various groups.

Specifying a force-group is meaningful only if the share is in a UNIX or mixed qtree. There is no need to set a force-group for shares in an NTFS volume or qtree because access to files in these shares is determined by Windows permissions, not UNIX GIDs.

If a force-group has been specified for a share, the following becomes true of the share:

- SMB users in the force-group who access this share are temporarily changed to the GID of the force-

group.

This GID enables them to access files in this share that are not accessible normally with their primary GID or UID.

- All files in this share created by SMB users belong to the same force-group, regardless of the primary GID of the file owner.

When SMB users try to access a file created by NFS, the SMB users' primary GIDs determine access rights.

The force-group does not affect how NFS users access files in this share. A file created by NFS acquires the GID from the file owner. Determination of access permissions is based on the UID and primary GID of the NFS user who is trying to access the file.

Using a force-group makes it easier to ensure that files can be accessed by SMB users belonging to various groups. For example, if you want to create a share to store the company's web pages and give write access to users in the Engineering and Marketing departments, you can create a share and give write access to a force-group named "webgroup1". Because of the force-group, all files created by SMB users in this share are owned by the "webgroup1" group. In addition, users are automatically assigned the GID of the "webgroup1" group when accessing the share. As a result, all the users can write to this share without you needing to manage the access rights of the users in the Engineering and Marketing departments.

Related information

[Creating an SMB share with the force-group share setting](#)

= Create an SMB share with the force-group share setting

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

You can create an SMB share with the force-group share setting if you want SMB users that access data on volumes or qtrees with UNIX file security to be regarded by ONTAP as belonging to the same UNIX group.

Step

1. Create the SMB share: `vserver cifs share create -vserver vserver_name -share -name share_name -path path -force-group-for-create UNIX_group_name`

If the UNC path (`\\\servername\sharename\filepath`) of the share contains more than 256 characters (excluding the initial "`\\"`" in the UNC path), then the **Security** tab in the Windows Properties box is unavailable. This is a Windows client issue rather than an ONTAP issue. To avoid this issue, do not create shares with UNC paths with more than 256 characters.

If you want to remove the force-group after the share is created, you can modify the share at any time and specify an empty string ("") as the value for the `-force-group-for-create` parameter. If you remove the force-group by modifying the share, all existing connections to this share continue to have the previously set force-group as the primary GID.

Example

The following command creates a "webpages" share that is accessible on the web in the `/corp/companyinfo` directory in which all files that SMB users create are assigned to the `webgroup1`

group:

```
vserver cifs share create -vserver vsl -share-name webpages -path /corp/companyinfo -force-group-for-create webgroup1
```

[Optimize SMB user access with the force-group share setting](#)

= View information about SMB shares using the MMC

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin../media/

You can view information about SMB shares on your SVM and perform some management tasks using the Microsoft Management Console (MMC). Before you can view the shares, you need to connect the MMC to the SVM.

About this task

You can perform the following tasks on shares contained within SVMs using the MMC:

- View shares
- View active sessions
- View open files
- Enumerate the list of sessions, files and tree connections in the system
- Close open files in the system
- Close open sessions
- Create/manage shares

The views displayed by the preceding capabilities are node specific and not cluster specific. Therefore, when you use the MMC to connect to the SMB server host name (that is, cifs01.domain.local), you are routed, based on how you have set up DNS, to a single LIF within your cluster.

The following functions are not supported in MMC for ONTAP:

- Creating new local users/groups
- Managing/viewing existing local users/groups
- Viewing events or performance logs
- Storage
- Services and applications

In instances where the operation is not supported, you might experience remote procedure call failed errors.

[FAQ: Using Windows MMC with ONTAP](#)

Steps

1. To open Computer Management MMC on any Windows server, in the **Control Panel**, select

Administrative Tools > Computer Management.

2. Select **Action > Connect to another computer.**

The Select Computer dialog box appears.

3. Type the name of the storage system or click **Browse** to locate the storage system.

4. Click **OK.**

The MMC connects to the SVM.

5. In the navigation pane, click **Shared Folders > Shares.**

A list of shares on the SVM is displayed in the right display pane.

6. To display the share properties for a share, double-click the share to open the **Properties** dialog box.

7. If you cannot connect to the storage system using MMC, you can add the user to the BUILTIN\Administrators group or BUILTIN\Power Users group by using one of the following commands on the storage system:

```
cifs users-and-groups local-groups add-members -vserver
<vserver_name> -group-name BUILTIN\Administrators -member-names
<domainuser>
```

```
cifs users-and-groups local-groups add-members -vserver
<vserver_name> -group-name "BUILTIN\Power Users" -member-names
<domainuser>
```

= Commands for managing SMB shares

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You use the vserver cifs share and vserver cifs share properties commands to manage SMB shares.

If you want to...	Use this command...
Create an SMB share	vserver cifs share create
Display SMB shares	vserver cifs share show
Modify an SMB share	vserver cifs share modify
Delete an SMB share	vserver cifs share delete
Add share properties to an existing share	vserver cifs share properties add

If you want to...	Use this command...
Remove share properties from an existing share	vserver cifs share properties remove
Display information about share properties	vserver cifs share properties show

See the man page for each command for more information.

= Secure file access by using SMB share ACLs

= Guidelines for managing SMB share-level ACLs

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can change share-level ACLs to give users more or less access rights to the share. You can configure share-level ACLs by using either Windows users and groups or UNIX users and groups.

After you create a share, by default, the share-level ACL gives read access to the standard group named Everyone. Read access in the ACL means that all users in the domain and all trusted domains have read-only access to the share.

You can change a share-level ACL by using the Microsoft Management Console (MMC) on a Windows client or the ONTAP command line.

The following guidelines apply when you use the MMC:

- The user and group names specified must be Windows names.
- You can specify only Windows permissions.

The following guidelines apply when you use the ONTAP command line:

- The user and group names specified can be Windows names or UNIX names.

If a user and group type is not specified when creating or modifying ACLs, the default type is Windows users and groups.

- You can specify only Windows permissions.

= Create SMB share access control lists

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Configuring share permissions by creating access control lists (ACLs) for SMB shares enables you to control the level of access to a share for users and groups.

About this task

You can configure share-level ACLs by using local or domain Windows user or group names or UNIX user or group names.

Before creating a new ACL, you should delete the default share ACL Everyone / Full Control, which poses a security risk.

In workgroup mode, the local domain name is the SMB server name.

Steps

1. Delete the default share ACL:
`vserver cifs share access-control delete -vserver vserver_name -share share_name -user-or-group everyone`
2. Configure the new ACL:

If you want to configure ACLs by using a...	Enter the command...
Windows user	<code>vserver cifs share access-control create -vserver vserver_name -share share_name -user-group-type windows -user-or-group Windows_domain_name\user_name -permission access_right</code>
Windows group	<code>vserver cifs share access-control create -vserver vserver_name -share share_name -user-group-type windows -user-or-group Windows_group_name -permission access_right</code>
UNIX user	<code>vserver cifs share access-control create -vserver vserver_name -share share_name -user-group-type unix-user -user-or-group UNIX_user_name -permission access_right</code>
UNIX group	<code>vserver cifs share access-control create -vserver vserver_name -share share_name -user-group-type unix-group -user-or-group UNIX_group_name -permission access_right</code>

3. Verify that the ACL applied to the share is correct by using the `vserver cifs share access-control show` command.

Example

The following command gives Change permissions to the "Sales Team" Windows group for the "sales" share on the "vs1.example.com`SVM:

```

cluster1::> vserver cifs share access-control create -vserver
vs1.example.com -share sales -user-or-group "Sales Team" -permission
Change

cluster1::> vserver cifs share access-control show
          Share      User/Group      User/Group  Access
Vserver      Name        Name        Type
Permission
-----
-----
vs1.example.com  c$          BUILTIN\Administrators windows
Full_Control
vs1.example.com  sales       DOMAIN\"Sales Team"    windows      Change

```

The following command gives Read permission to the “engineering” UNIX group for the “eng” share on the “vs2.example.com”SVM:

```

cluster1::> vserver cifs share access-control create -vserver
vs2.example.com -share eng -user-group-type unix-group -user-or-group
eng -permission Read

cluster1::> vserver cifs share access-control show
          Share      User/Group      User/Group
Access
Vserver      Name        Name        Type
Permission
-----
-----
vs2.example.com  c$          BUILTIN\Administrators windows
Full_Control
vs2.example.com  eng         engineering      unix-group  Read

```

The following commands give Change permission to the local Windows group named “Tiger Team” and Full_Control permission to the local Windows user named “Sue Chang” for the “datavol5” share on the “vs1”SVM:

```

cluster1::> vserver cifs share access-control create -vserver vs1
-share datavol5 -user-group-type windows -user-or-group "Tiger Team"
-permission Change

cluster1::> vserver cifs share access-control create -vserver vs1
-share datavol5 -user-group-type windows -user-or-group "Sue Chang"
-permission Full_Control

cluster1::> vserver cifs share access-control show -vserver vs1
      Share          User/Group          User/Group
Access          Vserver       Name        Name           Type
Permission
-----
-----
```

Access	Vserver	Name	Name	Type
Change	vs1	c\$	BUILTIN\Administrators	windows
Full_Control	vs1	datavol5	DOMAIN\"Tiger Team"	windows
Full_Control	vs1	datavol5	DOMAIN\"Sue Chang"	windows

= Commands for managing SMB share access control lists

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You need to know the commands for managing SMB access control lists (ACLs), which includes creating, displaying, modifying, and deleting them.

If you want to...	Use this command...
Create a new ACL	vserver cifs share access-control create
Display ACLs	vserver cifs share access-control show
Modify an ACL	vserver cifs share access-control modify
Delete an ACL	vserver cifs share access-control delete

= Secure file access by using file permissions

= Configure advanced NTFS file permissions using the Windows Security tab

```
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

You can configure standard NTFS file permissions on files and folders by using the **Windows Security** tab in the Windows Properties window.

Before you begin

The administrator performing this task must have sufficient NTFS permissions to change permissions on the selected objects.

About this task

Configuring NTFS file permissions is done on a Windows host by adding entries to NTFS discretionary access control lists (DACLs) that are associated with an NTFS security descriptor. The security descriptor is then applied to NTFS files and directories. These tasks are automatically handled by the Windows GUI.

Steps

1. From the **Tools** menu in Windows Explorer, select **Map network drive**.
2. Complete the **Map Network Drive** dialog box:
 - a. Select a **Drive** letter.
 - b. In the **Folder** box, type the CIFS server name containing the share that contains the data to which you want to apply permissions and the name of the share.

If your CIFS server name is “CIFS_SERVER” and your share is named “share1”, you should type \\CIFS_SERVER\share1.

You can specify the IP address of the data interface for the CIFS server instead of the CIFS server name.

- c. Click **Finish**.
- The drive you selected is mounted and ready with the Windows Explorer window displaying files and folders contained within the share.
3. Select the file or directory for which you want to set NTFS file permissions.
4. Right-click the file or directory, and then select **Properties**.
5. Select the **Security** tab.

The **Security** tab displays the list of users and groups for which NTFS permission are set. The **Permissions for** box displays a list of Allow and Deny permissions in effect for each user or group selected.

6. Click **Advanced**.

The Windows Properties window displays information about existing file permissions assigned to users and groups.
7. Click **Change Permissions**.

The Permissions window opens.

8. Perform the desired actions:

If you want to...	Do the following...
Set up advanced NTFS permissions for a new user or group	<ol style="list-style-type: none"> Click Add. In the Enter the object name to select box, type the name of the user or group that you want to add. Click OK.
Change advanced NTFS permissions from a user or group	<ol style="list-style-type: none"> In the Permissions entries: box, select the user or group whose advanced permissions you want to change. Click Edit.
Remove advanced NTFS permissions for a user or group	<ol style="list-style-type: none"> In the Permissions entries: box, select the user or group that you want to remove. Click Remove. Skip to Step 13.

If you are adding advanced NTFS permissions on a new user or group or changing NTFS advanced permissions on an existing user or group, the Permission Entry for <Object> box opens.

9. In the **Apply to** box, select how you want to apply this NTFS file permission entry.

If you are setting up NTFS file permissions on a single file, the **Apply to** box is not active. The **Apply to** setting defaults to **This object only**.

10. In the **Permissions** box, select the **Allow** or **Deny** boxes for the advanced permissions that you want to set on this object.

- To allow the specified access, select the **Allow** box.
 - To not allow the specified access, select the **Deny** box.
- You can set permissions on the following advanced rights:

◦ **Full control**

If you choose this advanced right, all other advanced rights are automatically chosen (either Allow or Deny rights).

- **Traverse folder / execute file**
- **List folder / read data**
- **Read attributes**
- **Read extended attributes**
- **Create files / write data**
- **Create folders / append data**
- **Write attributes**

- **Write extended attributes**
- **Delete subfolders and files**
- **Delete**
- **Read permissions**
- **Change permissions**
- **Take ownership**

If any of the advanced permission boxes are not selectable, it is because the permissions are inherited from the parent object.

11. If you want subfolders and files of this object to inherit these permissions, select the **Apply these permissions to objects and/or containers within this container only** box.
12. Click **OK**.
13. After you finish adding, removing, or editing NTFS permissions, specify the inheritance setting for this object:
 - Select the **Include inheritable permissions from this object's parent** box.

This is the default.

- Select the **Replace all child object permissions with inheritable permissions from this object** box.

This setting is not present in the Permissions box if you are setting NTFS file permissions on a single file.

Be cautious when selecting this setting. This setting removes all existing permissions on all child objects and replaces them with this object's permission settings. You could inadvertently remove permissions that you did not want removed. It is especially important when setting permissions in a mixed security-style volume or qtree. If child objects have a UNIX effective security style, propagating NTFS permissions to those child objects results in ONTAP changing these objects from UNIX security style to NTFS security style, and all UNIX permissions on those child objects are replaced with NTFS permissions.

- Select both boxes.
- Select neither box.

14. Click **OK** to close the **Permissions** box.
15. Click **OK** to close the **Advanced Security settings for <Object>** box.

For more information about how to set advanced NTFS permissions, see your Windows documentation.

Displaying information about file security on UNIX security-style volumes

= Configure NTFS file permissions using the ONTAP CLI

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can configure NTFS file permissions on files and directories using the ONTAP CLI. This enables you to configure NTFS file permissions without needing to connect to the data using an SMB share on a Windows Client.

You can configure NTFS file permissions by adding entries to NTFS discretionary access control lists (DACLs) that are associated with an NTFS security descriptor. The security descriptor is then applied to NTFS files and directories.

You can only configure NTFS file permissions using the command line. You cannot configure NFSv4 ACLs by using the CLI.

= How UNIX file permissions provide access control when accessing files over SMB

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

A FlexVol volume can have one of three types of security style: NTFS, UNIX, or mixed. You can access data over SMB regardless of security style; however, appropriate UNIX file permissions are needed to access data with UNIX effective security.

When data is accessed over SMB, there are several access controls used when determining whether a user is authorized to perform a requested action:

- Export permissions

Configuring export permissions for SMB access is optional.

- Share permissions
- File permissions

The following types of file permissions might be applied to the data on which the user wants to perform an action:

- NTFS
- UNIX NFSv4 ACLs
- UNIX mode bits

For data with NFSv4 ACLs or UNIX mode bits set, UNIX style permissions are used to determine file access rights to the data. The SVM administrator needs to set the appropriate file permission to ensure that users have the rights to perform the desired action.

Data in a mixed security-style volume might have either NTFS or UNIX effective security style. If the data has UNIX effective security style, then NFSv4 permissions or UNIX mode bits are used when determining file access rights to the data.

= Secure file access by using Dynamic Access Control (DAC)
= Secure file access by using Dynamic Access Control (DAC) overview
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin../media/

You can secure access by using Dynamic Access Control and by creating central access policies in Active Directory and applying them to files and folders on SVMs through applied Group Policy Objects (GPOs). You can configure auditing to use central access policy staging events to see the effects of changes to central access policies before you apply them.

== Additions to CIFS credentials

Before Dynamic Access Control, a CIFS credential included a security principal's (the user's) identity and Windows group membership. With Dynamic Access Control, three more types of information are added to the credential—device identity, device claims, and user claims:

- Device identity

The analog of the user's identity information, except it is the identity and group membership of the device that the user is logging in from.

- Device claims

Assertions about a device security principal. For example, a device claim might be that it is a member of a specific OU.

- User claims

Assertions about a user security principal. For example, a user claim might be that their AD account is a member of a specific OU.

== Central access policies

Central access policies for files enable organizations to centrally deploy and manage authorization policies that include conditional expressions using user groups, user claims, device claims, and resource properties.

For example, for accessing high business impact data, a user needs to be a full time employee and only have access to the data from a managed device. Central access policies are defined in Active Directory and distributed to file servers via the GPO mechanism.

== Central access policy staging with advanced auditing

Central access policies can be “staged”, in which case they are evaluated in a “what-if” manner during file access checks. The results of what would have happened if the policy was in effect and how that differs from what is currently configured are logged as an audit event. In this way, administrators can use audit event logs to study the impact of an access policy change before actually putting the policy in play. After evaluating the impact of an access policy change, the policy can be deployed via GPOs to the desired SVMs.

= Supported Dynamic Access Control functionality

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

If you want to use Dynamic Access Control (DAC) on your CIFS server, you need to understand how ONTAP supports Dynamic Access Control functionality in Active Directory environments.

== Supported for Dynamic Access Control

ONTAP supports the following functionality when Dynamic Access Control is enabled on the CIFS server:

Functionality	Comments
Claims into the file system	Claims are simple name and value pairs that state some truth about a user. User credentials now contain claim information, and security descriptors on files can perform access checks that include claims checks. This gives administrators a finer level of control over who can access files.
Conditional expressions to file access checks	When modifying the security parameters of a file, users can now add arbitrarily complex conditional expressions to the file's security descriptor. The conditional expression can include checks for claims.

Functionality	Comments
Central control of file access via central access policies	Central access policies are a kind of ACL stored in Active Directory that can be tagged to a file. Access to the file is only granted if the access checks of both the security descriptor on disk and the tagged central access policy allows access. This gives administrators the ability to control access to files from a central location (AD) without having to modify the security descriptor on disk.
Central access policy staging	Adds the ability to try out security changes without affecting actual file access, by “staging” a change to the central access policies, and seeing the effect of the change in an audit report.
Support for displaying information about central access policy security by using the ONTAP CLI	Extends the <code>vserver security file-directory show</code> command to display information about applied central access policies.
Security tracing that includes central access policies	Extends the <code>vserver security trace</code> command family to display results that include information about applied central access policies.

== Unsupported for Dynamic Access Control

ONTAP does not support the following functionality when Dynamic Access Control is enabled on the CIFS server:

Functionality	Comments
Automatic classification of NTFS file system objects	This is an extension to the Windows File Classification Infrastructure that is not supported in ONTAP.
Advanced auditing other than central access policy staging	Only central access policy staging is supported for advanced auditing.

= Considerations when using Dynamic Access Control and central access policies with CIFS servers

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

There are certain considerations you must keep in mind when using Dynamic Access Control (DAC) and central access policies to secure files and folders on CIFS servers.

== NFS access can be denied to root if policy rule applies to domain\administrator user

Under certain circumstances, NFS access to root might be denied when central access policy security is

applied to the data that the root user is attempting to access. The issue occurs when the central access policy contains a rule that is applied to the domain\administrator and the root account is mapped to the domain\administrator account.

Instead of applying a rule to the domain\administrator user, you should apply the rule to a group with administrative privileges, such as the domain\administrators group. In this way, you can map root to the domain\administrator account without root being impacted by this issue.

== CIFS server's BUILTIN\Administrators group has access to resources when the applied central access policy is not found in Active Directory

It is possible that resources contained within the CIFS server have central access policies applied to them, but when the CIFS server uses the central access policy's SID to attempt to retrieve information from Active Directory, the SID does not match any existing central access policy SIDs in Active Directory. Under these circumstances, the CIFS server applies the local default recovery policy for that resource.

The local default recovery policy allows the CIFS server's BUILTIN\Administrators group access to that resource.

= Enable or disable Dynamic Access Control overview

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

The option that enables you to use Dynamic Access Control (DAC) to secure objects on your CIFS server is disabled by default. You must enable the option if you want to use Dynamic Access Control on your CIFS server. If you later decide that you do not want to use Dynamic Access Control to secure objects stored on the CIFS server, you can disable the option.

About this task

Once Dynamic Access Control is enabled, the file system can contain ACLs with Dynamic Access Control-related entries. If Dynamic Access Control is disabled, the current Dynamic Access Control entries will be ignored, and new ones will not be allowed.

This option is available only at the advanced privilege level.

Step

1. Set the privilege level to advanced: set -privilege advanced
2. Perform one of the following actions:

If you want Dynamic Access Control to be...	Enter the command...
Enabled	vserver cifs options modify -vserver <u>vserver_name</u> -is-dac-enabled true
Disabled	vserver cifs options modify -vserver <u>vserver_name</u> -is-dac-enabled false

3. Return to the administrator privilege level: set -privilege admin

[Configuring central access policies to secure data on CIFS servers](#)

= Manage ACLs that contain Dynamic Access Control ACEs when Dynamic Access Control is disabled

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you have resources that have ACLs applied with Dynamic Access Control ACEs and you disable Dynamic Access Control on the storage virtual machine (SVM), you must remove the Dynamic Access Control ACEs before you can manage the non-Dynamic Access Control ACEs on that resource.

About this task

After Dynamic Access Control is disabled, you cannot remove existing non-Dynamic Access Control ACEs or add new non-Dynamic Access Control ACEs until you have removed the existing Dynamic Access Control ACEs.

You can use whichever tool you normally use to manage ACLs to perform these steps.

Steps

1. Determine what Dynamic Access Control ACEs are applied to the resource.
2. Remove the Dynamic Access Control ACEs from the resource.
3. Add or remove non-Dynamic Access Control ACEs as desired from the resource.

= Configure central access policies to secure data on CIFS servers

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

There are several steps that you must take to secure access to data on the CIFS server using central access policies, including enabling Dynamic Access Control (DAC) on the CIFS server, configuring central access policies in Active Directory, applying the central access policies to Active Directory containers with GPOs, and enabling GPOs on the CIFS server.

Before you begin

- The Active Directory must be configured to use central access policies.
- You must have sufficient access on the Active Directory domain controllers to create central access policies and to create and apply GPOs to the containers that contain the CIFS servers.
- You must have sufficient administrative access on the storage virtual machine (SVM) to execute the necessary commands.

About this task

Central access policies are defined and applied to group policy objects (GPOs) on Active Directory. You can consult the Microsoft TechNet Library for instructions about configuring central access policies and GPOs.

[Microsoft TechNet Library](#)

Steps

1. Enable Dynamic Access Control on the SVM if it is not already enabled by using the `vserver cifs options modify` command.

```
vserver cifs options modify -vserver vs1 -is-dac-enabled true
```

2. Enable group policy objects (GPOs) on the CIFS server if they are not already enabled by using the `vserver cifs group-policy modify` command.

```
vserver cifs group-policy modify -vserver vs1 -status enabled
```

3. Create central access rules and central access policies on Active Directory.
4. Create a group policy object (GPO) to deploy the central access policies on Active Directory.

5. Apply the GPO to the container where the CIFS server computer account is located.

6. Manually update the GPOs applied to the CIFS server by using the `vserver cifs group-policy update` command.

```
vserver cifs group-policy update -vserver vs1
```

7. Verify that the GPO central access policy is applied to the resources on the CIFS server by using the `vserver cifs group-policy show-applied` command.

The following example shows that the Default Domain Policy has two central access policies that are applied to the CIFS server:

```
vserver cifs group-policy show-applied
```

```

= Display information about Dynamic Access Control security

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..../media/

You can display information about Dynamic Access Control (DAC) security on NTFS volumes and on data with NTFS effective security on mixed security-style volumes. This includes information about conditional ACEs, resource ACEs, and central access policy ACEs. You can use the results to validate your security configuration or to troubleshoot file access issues.

About this task

You must supply the name of the storage virtual machine (SVM) and the path to the data whose file or folder security information you want to display. You can display the output in summary form or as a detailed list.

Step

1. Display file and directory security settings with the desired level of detail:

If you want to display information...	Enter the following command...
In summary form	<code>vserver security file-directory show -vserver vserver_name -path path</code>
With expanded detail	<code>vserver security file-directory show -vserver vserver_name -path path -expand-mask true</code>
Where output is displayed with group and user SIDs	<code>vserver security file-directory show -vserver vserver_name -path path -lookup-names false</code>
About file and directory security for files and directories where the hexadecimal bit mask is translated to textual format	<code>vserver security file-directory show -vserver vserver_name -path path -textual-mask true</code>

Examples

The following example displays Dynamic Access Control security information about the path /vol1 in SVM vs1:

```

cluster1::> vserver security file-directory show -vserver vs1 -path
/vol1
          Vserver: vs1
          File Path: /vol1
          File Inode Number: 112
          Security Style: mixed

= Revert considerations for Dynamic Access Control

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You should be aware of what happens when reverting to a version of ONTAP that does not support Dynamic Access Control (DAC) and what you must do before and after reverting.

If you want to revert the cluster to a version of ONTAP that does not support Dynamic Access Control and Dynamic Access Control is enabled on one or more the storage virtual machines (SVMs), you must do the following before reverting:

- You must disable Dynamic Access Control on all SVMs that have it enabled on the cluster.
- You must modify any auditing configurations on the cluster that contain the `cap-staging` event type to use only the `file-op` event type.

You must understand and act on some important revert considerations for files and folders with Dynamic Access Control ACEs:

- If the cluster is reverted, existing Dynamic Access Control ACEs are not removed; however, they will be ignored in file access checks.
- Since Dynamic Access Control ACEs are ignored after reversion, access to files will change on files with Dynamic Access Control ACEs.

This could allow users to access files they previously could not, or not be able to access files that they previously could.

- You should apply non-Dynamic Access Control ACEs to the affected files to restore their previous level of security.

This can be done either before reverting or immediately after reversion completes.

Since Dynamic Access Control ACEs are ignored after reversion, it is not required that you remove them when applying non-Dynamic Access Control ACEs to the affected files. However, if desired, you can manually remove them.

= Where to find additional information about configuring and using Dynamic Access Control and central access policies

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

Additional resources are available to help you configure and use Dynamic Access Control and central access policies.

You can find information about how to configure Dynamic Access Control and central access policies on Active Directory in the Microsoft TechNet Library.

[Microsoft TechNet: Dynamic Access Control Scenario Overview](#)

[Microsoft TechNet: Central Access Policy Scenario](#)

The following references can help you configure the SMB server to use and support Dynamic Access Control and central access policies:

- [Using GPOs on the SMB server](#)

Applying Group Policy Objects to SMB servers

- Configuring NAS auditing on the SMB server

SMB and NFS auditing and security tracing

= Secure SMB access using export policies

= How export policies are used with SMB access

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If export policies for SMB access are enabled on the CIFS server, export policies are used when controlling access to SVM volumes by SMB clients. To access data, you can create an export policy that allows SMB access and then associate the policy with the volumes containing SMB shares.

An export policy has one or more rules applied to it that specifies which clients are allowed access to the data and what authentication protocols are supported for read-only and read-write access. You can configure export policies to allow access over SMB to all clients, a subnet of clients, or a specific client and to allow authentication using Kerberos authentication, NTLM authentication, or both Kerberos and NTLM authentication when determining read-only and read-write access to data.

After processing all export rules applied to the export policy, ONTAP can determine whether the client is granted access and what level of access is granted. Export rules apply to client machines, not to Windows users and groups. Export rules do not replace Windows user and group-based authentication and authorization. Export rules provide another layer of access security in addition to share and file-access permissions. You associate exactly one export policy with each volume to configure client access to the volume. Each SVM can contain multiple export policies. This enables you to do the following for SVMs with multiple volumes:

- Assign different export policies to each volume of the SVM for individual client access control to each volume in the SVM.
- Assign the same export policy to multiple volumes of the SVM for identical client access control without having to create a new export policy for each volume.

You associate exactly one export policy to each volume to configure client access to the volume. Each SVM can contain multiple export policies. This enables you to do the following for SVMs with multiple volumes:

- Assign different export policies to each volume of the SVM for individual client access control to each volume in the SVM.
- Assign the same export policy to multiple volumes of the SVM for identical client access control without having to create a new export policy for each volume.

Each SVM has at least one export policy called “default”, which contains no rules. You cannot delete this export policy, but you can rename or modify it. Each volume on the SVM by default is associated with the default export policy. If export policies for SMB access is disabled on the SVM, the “default” export policy has no effect on SMB access.

You can configure rules that provide access to both NFS and SMB hosts and associate that rule with an export policy, which can then be associated with the volume that contains data to which both NFS and

SMB hosts need access. Alternatively, if there are some volumes where only SMB clients require access, you can configure an export policy with rules that only allow access using the SMB protocol and that uses only Kerberos or NTLM (or both) for authentication for read-only and write access. The export policy is then associated to the volumes where only SMB access is desired.

If export policies for SMB is enabled and a client makes an access request that is not permitted by the applicable export policy, the request fails with a permission-denied message. If a client does not match any rule in the volume's export policy, then access is denied. If an export policy is empty, then all accesses are implicitly denied. This is true even if the share and file permissions would otherwise permit access. This means that you must configure your export policy to minimally allow the following on volumes containing SMB shares:

- Allow access to all clients or the appropriate subset of clients
- Allow access over SMB
- Allow appropriate read-only and write access by using Kerberos or NTLM authentication (or both)

For information about configuring and managing export policies, see [NFS management](#).

= How export rules work

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

Export rules are the functional elements of an export policy. Export rules match client access requests to a volume against specific parameters you configure to determine how to handle the client access requests.

An export policy must contain at least one export rule to allow access to clients. If an export policy contains more than one rule, the rules are processed in the order in which they appear in the export policy. The rule order is dictated by the rule index number. If a rule matches a client, the permissions of that rule are used and no further rules are processed. If no rules match, the client is denied access.

You can configure export rules to determine client access permissions using the following criteria:

- The file access protocol used by the client sending the request, for example, NFSv4 or SMB.
- A client identifier, for example, host name or IP address.
- The security type used by the client to authenticate, for example, Kerberos v5, NTLM, or AUTH_SYS.

If a rule specifies multiple criteria, the client must match all of them for the rule to apply.

Example

The export policy contains an export rule with the following parameters:

- -protocol nfs3
- -clientmatch 10.1.16.0/255.255.255.0
- -rorule any
- -rwrule any

The client access request is sent using the NFSv3 protocol and the client has the IP address 10.1.17.37.

Even though the client access protocol matches, the IP address of the client is in a different subnet from the one specified in the export rule. Therefore, client matching fails and this rule does not apply to this client.

Example

The export policy contains an export rule with the following parameters:

- -protocol nfs
- -clientmatch 10.1.16.0/255.255.255.0
- -rorule any
- -rwrule any

The client access request is sent using the NFSv4 protocol and the client has the IP address 10.1.16.54.

The client access protocol matches and the IP address of the client is in the specified subnet. Therefore, client matching is successful and this rule applies to this client. The client gets read-write access regardless of its security type.

Example

The export policy contains an export rule with the following parameters:

- -protocol nfs3
- -clientmatch 10.1.16.0/255.255.255.0
- -rorule any
- -rwrule krb5,ntlm

Client #1 has the IP address 10.1.16.207, sends an access request using the NFSv3 protocol, and authenticated with Kerberos v5.

Client #2 has the IP address 10.1.16.211, sends an access request using the NFSv3 protocol, and authenticated with AUTH_SYS.

The client access protocol and IP address matches for both clients. The read-only parameter allows read-only access to all clients regardless of the security type they authenticated with. Therefore both clients get read-only access. However, only client #1 gets read-write access because it used the approved security type Kerberos v5 to authenticate. Client #2 does not get read-write access.

= Examples of export policy rules that restrict or allow access over SMB

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..../media/

The examples show how to create export policy rules that restrict or allow access over SMB on an SVM that has export policies for SMB access enabled.

Export policies for SMB access are disabled by default. You need to configure export policy rules that restrict or allow access over SMB only if you have enabled export policies for SMB access.

== Export rule for SMB access only

The following command creates an export rule on the SVM named “vs1” that has the following configuration:

- Policy name: cifs1
- Index number: 1
- Client match: Matches only clients on the 192.168.1.0/24 network
- Protocol: Only enables SMB access
- Read-only access: To clients using NTLM or Kerberos authentication
- Read-write access: To clients using Kerberos authentication

```
cluster1::> vserver export-policy rule create -vserver vs1 -policyname  
cifs1 -ruleindex 1 -protocol cifs -clientmatch  
192.168.1.0/255.255.255.0 -rorule krb5,ntlm -rwrule krb5
```

== Export rule for SMB and NFS access

The following command creates an export rule on the SVM named “vs1” that has the following configuration:

- Policy name: cifs nfs1
- Index number: 2
- Client match: Matches all clients
- Protocol: SMB and NFS access
- Read-only access: To all clients
- Read-write access: To clients using Kerberos (NFS and SMB) or NTLM authentication (SMB)
- Mapping for UNIX user ID 0 (zero): Mapped to user ID 65534 (which typically maps to the user name nobody)
- Suid and sgid access: Allows

```
cluster1::> vserver export-policy rule create -vserver vs1 -policyname  
cifs nfs1 -ruleindex 2 -protocol cifs,nfs -clientmatch 0.0.0.0/0 -rorule  
any -rwrule krb5,ntlm -anon 65534 -allow-suid true
```

== Export rule for SMB access using NTLM only

The following command creates an export rule on the SVM named “vs1” that has the following configuration:

- Policy name: nt lm1
- Index number: 1
- Client match: Matches all clients
- Protocol: Only enables SMB access
- Read-only access: Only to clients using NTLM

- Read-write access: Only to clients using NTLM

 If you configure the read-only option or the read-write option for NTLM-only access, you must use IP address-based entries in the client match option. Otherwise, you receive access denied errors. This is because ONTAP uses Kerberos Service Principal Names (SPN) when using a host name to check on the client's access rights. NTLM authentication does not support SPN names.

```
cluster1::> vserver export-policy rule create -vserver vs1 -policyname ntlm1 -ruleindex 1 -protocol cifs -clientmatch 0.0.0.0/0 -rorule ntlm -rwrule ntlm
```

= Enable or disable export policies for SMB access

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can enable or disable export policies for SMB access on storage virtual machines (SVMs). Using export policies to control SMB access to resources is optional.

Before you begin

The following are the requirements for enabling export policies for SMB:

- The client must have a “PTR” record in DNS before you create the export rules for that client.
- An additional set of “A” and “PTR” records for host names is required if the SVM provides access to NFS clients and the host name you want to use for NFS access is different from the CIFS server name.

About this task

When setting up a new CIFS server on your SVM, the use of export policies for SMB access is disabled by default. You can enable export policies for SMB access if you want to control access based on authentication protocol or on client IP addresses or host names. You can enable or disable export policies for SMB access at any time.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Enable or disable export policies:
 - Enable export policies: `vserver cifs options modify -vserver vserver_name -is-exportpolicy-enabled true`
 - Disable export policies: `vserver cifs options modify -vserver vserver_name -is-exportpolicy-enabled false`
3. Return to the admin privilege level: `set -privilege admin`

Example

The following example enables the use of export policies to control SMB client access to resources on SVM vs1:

```

cluster1::> set -privilege advanced
Warning: These advanced commands are potentially dangerous; use them
only when directed to do so by technical support personnel.
Do you wish to continue? (y or n): y

cluster1::*> vserver cifs options modify -vserver vs1 -is-exportpolicy
-enabled true

cluster1::*> set -privilege admin

```

= Secure file access by using Storage-Level Access Guard

= Secure file access by using Storage-Level Access Guard
 :icons: font
 :relative_path: ./smb-admin/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

In addition to securing access by using native file-level and export and share security, you can configure Storage-Level Access Guard, a third layer of security applied by ONTAP at the volume level. Storage-Level Access Guard applies to access from all NAS protocols to the storage object to which it is applied.

Only NTFS access permissions are supported. For ONTAP to perform security checks on UNIX users for access to data on volumes for which Storage-Level Access Guard has been applied, the UNIX user must map to a Windows user on the SVM that owns the volume.

== Storage-Level Access Guard behavior

- Storage-Level Access Guard applies to all the files or all the directories in a storage object.

Because all files or directories in a volume are subject to Storage-Level Access Guard settings, inheritance through propagation is not required.

- You can configure Storage-Level Access Guard to apply to files only, to directories only, or to both files and directories within a volume.

- File and directory security

Applies to every directory and file within the storage object. This is the default setting.

- File security

Applies to every file within the storage object. Applying this security does not affect access to, or auditing of, directories.

- Directory security

Applies to every directory within the storage object. Applying this security does not affect access to, or auditing of, files.

- Storage-Level Access Guard is used to restrict permissions.

It will never give extra access permissions.

- If you view the security settings on a file or directory from an NFS or SMB client, you do not see the Storage-Level Access Guard security.

It's applied at the storage object level and stored in the metadata used to determine the effective permissions.

- Storage-level security cannot be revoked from a client, even by a system (Windows or UNIX) administrator.

It is designed to be modified by storage administrators only.

- You can apply Storage-Level Access Guard to volumes with NTFS or mixed security style.
- You can apply Storage-Level Access Guard to volumes with UNIX security style as long as the SVM containing the volume has a CIFS server configured.
- When volumes are mounted under a volume junction path and if Storage-Level Access Guard is present on that path, it will not be propagated to volumes mounted under it.
- The Storage-Level Access Guard security descriptor is replicated with SnapMirror data replication and with SVM replication.
- There is special dispensation for virus scanners.

Exceptional access is allowed to these servers to screen files and directories, even if Storage-Level Access Guard denies access to the object.

- FPolicy notifications are not sent if access is denied because of Storage-Level Access Guard.

== Order of access checks

Access to a file or directory is determined by the combined effect of the export or share permissions, the Storage-Level Access Guard permissions set on volumes, and the native file permissions applied to files and/or directories. All levels of security are evaluated to determine what the effective permissions a file or directory has. The security access checks are performed in the following order:

1. SMB share or NFS export-level permissions
2. Storage-Level Access Guard
3. NTFS file/folder access control lists (ACLs), NFSv4 ACLs, or UNIX mode bits

= Use cases for using Storage-Level Access Guard

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Storage-Level Access Guard provides additional security at the storage level, which is not visible from a client side; therefore, it cannot be revoked by any of the users or administrators from their desktops. There are certain use cases where the ability to control access at the storage level is beneficial.

Typical use cases for this feature include the following scenarios:

- Intellectual property protection by auditing and controlling all users' access at the storage level

- Storage for financial services companies, including banking and trading groups
- Government services with separate file storage for individual departments
- Universities protecting all student files

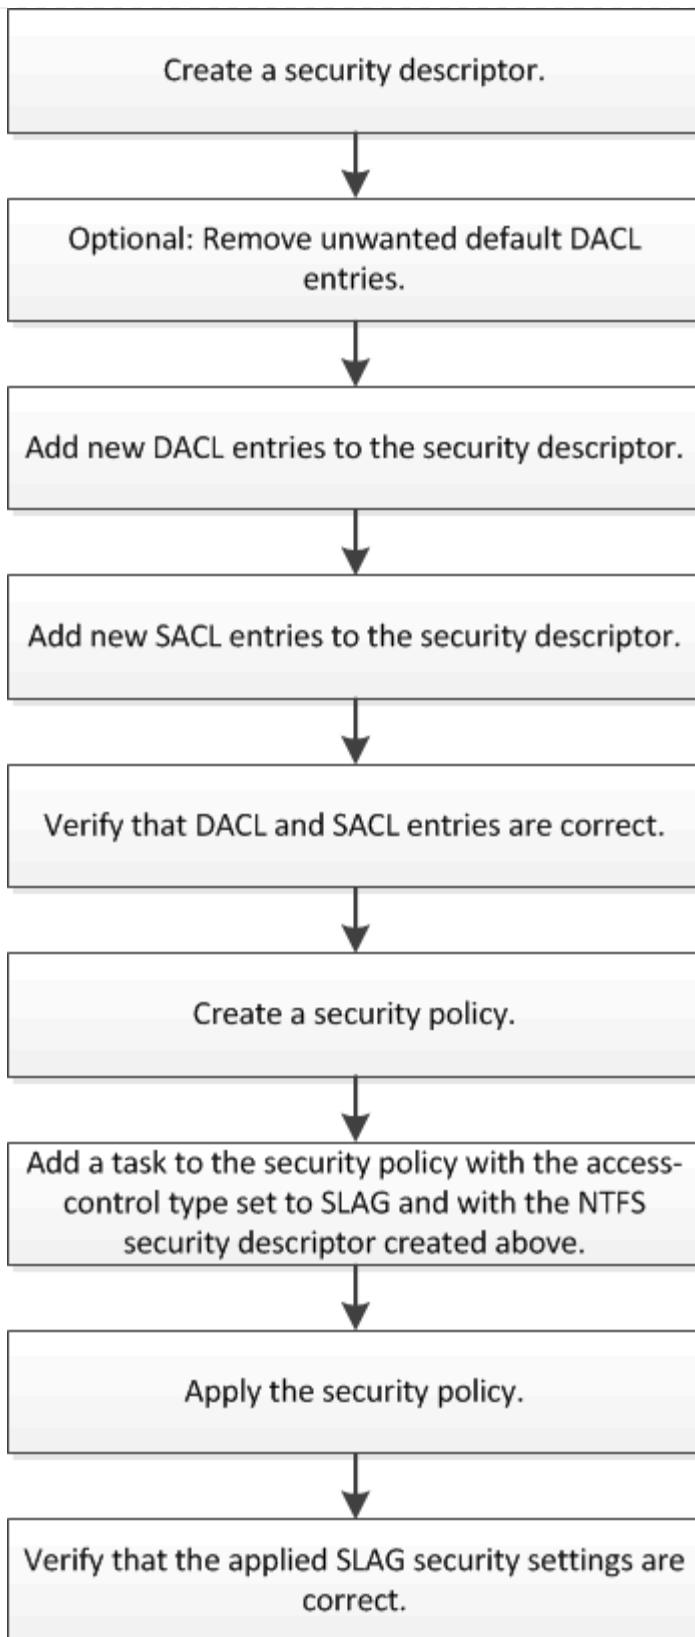

= Workflow to configure Storage-Level Access Guard

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The workflow to configure Storage-Level Access Guard (SLAG) uses the same ONTAP CLI commands that you use to configure NTFS file permissions and auditing policies. Instead of configuring file and directory access on a designated target, you configure SLAG on the designated storage virtual machine (SVM) volume.

[Configuring Storage-Level Access Guard](#)

= Configure Storage-Level Access Guard
:icons: font

```
:relative_path: ./smb-admin/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

There are a number of steps you need to follow to configure Storage-Level Access Guard on a volume or qtree. Storage-Level Access Guard provides a level of access security that is set at the storage level. It provides security that applies to all accesses from all NAS protocols to the storage object to which it has been applied.

Steps

1. Create a security descriptor by using the vserver security file-directory ntfs create command.

```
vserver security file-directory ntfs create -vserver vs1 -ntfs-sd sd1  
vserver security file-directory ntfs show -vserver vs1
```

```
Vserver: vs1  
  
NTFS Security      Owner Name  
Descriptor Name  
-----  
sd1                -
```

A security descriptor is created with the following four default DACL access control entries (ACEs):

```
Vserver: vs1  
NTFS Security Descriptor Name: sd1  
  
Account Name      Access          Access          Apply To  
                  Type            Rights           -----  
-----  
BUILTIN\Administrators          allow        full-control    this-folder, sub-  
folders, files  
BUILTIN\Users              allow        full-control    this-folder, sub-  
folders, files  
CREATOR OWNER            allow        full-control    this-folder, sub-  
folders, files  
NT AUTHORITY\SYSTEM          allow        full-control    this-folder, sub-  
folders, files
```

If you do not want to use the default entries when configuring Storage-Level Access Guard, you can remove them prior to creating and adding your own ACEs to the security descriptor.

2. Remove any of the default DACL ACEs from the security descriptor that you do not want configured with Storage-Level Access Guard security:

- a. Remove any unwanted DACL ACEs by using the vserver security file-directory ntfs dacl remove command.

In this example, three default DACL ACEs are removed from the security descriptor: BUILTIN\Administrators, BUILTIN\Users, and CREATOR OWNER.

```
vserver security file-directory ntfs dacl remove -vserver vs1 -ntfs-sd sd1 -access-type allow -account builtin\users vserver security file-directory ntfs dacl remove -vserver vs1 -ntfs-sd sd1 -access-type allow -account builtin\administrators vserver security file-directory ntfs dacl remove -vserver vs1 -ntfs-sd sd1 -access-type allow -account "creator owner"
```

- b. Verify that the DACL ACEs you do not want to use for Storage-Level Access Guard security are removed from the security descriptor by using the vserver security file-directory ntfs dacl show command.

In this example, the output from the command verifies that three default DACL ACEs have been removed from the security descriptor, leaving only the NT AUTHORITY\SYSTEM default DACL ACE entry:

```
vserver security file-directory ntfs dacl show -vserver vs1
```

```
Vserver: vs1
NTFS Security Descriptor Name: sd1

  Account Name      Access      Access          Apply To
              Type        Rights
  -----
  NT AUTHORITY\SYSTEM
                  allow     full-control   this-folder, sub-
folders, files
```

3. Add one or more DACL entries to a security descriptor by using the vserver security file-directory ntfs dacl add command.

In this example, two DACL ACEs are added to the security descriptor:

```
vserver security file-directory ntfs dacl add -vserver vs1 -ntfs-sd sd1 -access-type allow -account example\engineering -rights full-control -apply-to this-folder,sub-folders,files vserver security file-directory ntfs dacl add -vserver vs1 -ntfs-sd sd1 -access-type allow -account "example\Domain Users" -rights read -apply-to this-folder,sub-folders,files
```

4. Add one or more SACL entries to a security descriptor by using the vserver security file-directory ntfs sacl add command.

In this example, two SACL ACEs are added to the security descriptor:

```
vserver security file-directory ntfs sacl add -vserver vs1 -ntfs-sd sd1
```

```
-access-type failure -account "example\Domain Users" -rights read -apply-to  
this-folder,sub-folders,files vserver security file-directory ntfs sacl add  
-vserver vs1 -ntfs-sd sd1 -access-type success -account example\engineering  
-rights full-control -apply-to this-folder,sub-folders,files
```

5. Verify that the DACL and SACL ACEs are configured correctly by using the vserver security file-directory ntfs dacl show and vserver security file-directory ntfs sacl show commands, respectively.

In this example, the following command displays information about DACL entries for security descriptor “sd1”:

```
vserver security file-directory ntfs dacl show -vserver vs1 -ntfs-sd sd1
```

```
Vserver: vs1  
NTFS Security Descriptor Name: sd1  
  
Account Name      Access      Access          Apply To  
                  Type        Rights  
-----  -----  -----  
EXAMPLE\Domain Users  
                  allow       read           this-folder, sub-  
folders, files  
EXAMPLE\engineering  
                  allow       full-control   this-folder, sub-  
folders, files  
NT AUTHORITY\SYSTEM  
                  allow       full-control   this-folder, sub-  
folders, files
```

In this example, the following command displays information about SACL entries for security descriptor “sd1”:

```
vserver security file-directory ntfs sacl show -vserver vs1 -ntfs-sd sd1
```

```

Vserver: vs1
    NTFS Security Descriptor Name: sd1

    Account Name      Access      Access          Apply To
                  Type        Rights
    -----
    EXAMPLE\Domain Users
                    failure   read           this-folder, sub-
folders, files
    EXAMPLE\engineering
                    success   full-control   this-folder, sub-
folders, files

```

6. Create a security policy by using the vserver security file-directory policy create command.

The following example creates a policy named “policy1”:

```
vserver security file-directory policy create -vserver vs1 -policy-name
policy1
```

7. Verify that the policy is correctly configured by using the vserver security file-directory policy show command.

```
vserver security file-directory policy show
```

Vserver	Policy Name
-----	-----
vs1	policy1

8. Add a task with an associated security descriptor to the security policy by using the vserver security file-directory policy-task add command with the –access-control parameter set to slag.

Even though a policy can contain more than one Storage-Level Access Guard task, you cannot configure a policy to contain both file-directory and Storage-Level Access Guard tasks. A policy must contain either all Storage-Level Access Guard tasks or all file-directory tasks.

In this example, a task is added to the policy named “policy1”, which is assigned to security descriptor “sd1”. It is assigned to the /datavol1 path with the access control type set to “slag”.

```
vserver security file-directory policy task add -vserver vs1 -policy-name
policy1 -path /datavol1 -access-control slag -security-type ntfs -ntfs-mode
propagate -ntfs-sd sd1
```

9. Verify that the task is configured correctly by using the vserver security file-directory policy task show command.

```
vserver security file-directory policy task show -vserver vs1 -policy-name policy1
```

Vserver:	vs1	Policy:	policy1			
Index	File/Folder	Access	Security	NTFS		NTFS
Security	Path	Control	Type	Mode		
Descriptor	Name					
-----	-----	-----	-----	-----	-----	-----
-----	-----	-----	-----	-----	-----	-----
1	/datavol1	slag	ntfs	propagate	sd1	

10. Apply the Storage-Level Access Guard security policy by using the vserver security file-directory policy apply command.

```
vserver security file-directory apply -vserver vs1 -policy-name policy1
```

The job to apply the security policy is scheduled.

11. Verify that the applied Storage-Level Access Guard security settings are correct by using the vserver security file-directory show command.

In this example, the output from the command shows that Storage-Level Access Guard security has been applied to the NTFS volume /datavol1. Even though the default DACL allowing Full Control to Everyone remains, Storage-Level Access Guard security restricts (and audits) access to the groups defined in the Storage-Level Access Guard settings.

```
vserver security file-directory show -vserver vs1 -path /datavol1
```

```
Vserver: vs1

= Effective SLAG matrix

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can configure SLAG on a volume or a qtree or both. The SLAG matrix defines on which volume or qtree is the SLAG configuration applicable under various scenarios listed in the table.

	Volume SLAG in an AFS	Volume SLAG in a Snapshot copy	Qtree SLAG in an AFS	Qtree SLAG in a Snapshot copy
Volume access in an Access File System (AFS)	YES	NO	N/A	N/A
Volume access in a Snapshot copy	YES	NO	N/A	N/A
Qtree access in an AFS (when SLAG is present in the qtree)	NO	NO	YES	NO
Qtree access in an AFS (when SLAG is not present in qtree)	YES	NO	NO	NO
Qtree access in Snapshot copy (when SLAG is present in the qtree AFS)	NO	NO	YES	NO
Qtree access in Snapshot copy (when SLAG is not present in the qtree AFS)	YES	NO	NO	NO

= Display information about Storage-Level Access Guard

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Storage-Level Access Guard is a third layer of security applied on a volume or qtree. Storage-Level Access Guard settings cannot be viewed by using the Windows Properties window. You must use the ONTAP CLI to view information about Storage-Level Access Guard security, which you can use to validate your configuration or to

troubleshoot file access issues.

About this task

You must supply the name of the storage virtual machine (SVM) and the path to the volume or qtree whose Storage-Level Access Guard security information you want to display. You can display the output in summary form or as a detailed list.

Step

1. Display Storage-Level Access Guard security settings with the desired level of detail:

If you want to display information...	Enter the following command...
In summary form	<code>vserver security file-directory show -vserver vserver_name -path path</code>
With expanded detail	<code>vserver security file-directory show -vserver vserver_name -path path -expand-mask true</code>

Examples

The following example displays Storage-Level Access Guard security information for the NTFS security-style volume with the path /datavol1 in SVM vs1:

```
cluster::> vserver security file-directory show -vserver vs1 -path /datavol1
```

```
          Vserver: vs1
          File Path: /datavol1

= Remove Storage-Level Access Guard

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can remove Storage-Level Access Guard on a volume or qtree if you no longer want set access security at the storage level. Removing Storage-Level Access Guard does not modify or remove regular NTFS file and directory security.

Steps

1. Verify that the volume or qtree has Storage-Level Access Guard configured by using the `vserver security file-directory show` command.

```
vserver security file-directory show -vserver vs1 -path /datavol2
```

```

        Vserver: vs1
        File Path: /datavol2
        File Inode Number: 99
        Security Style: ntfs
        Effective Style: ntfs
        DOS Attributes: 10
        DOS Attributes in Text: ----D---
        Expanded Dos Attributes: -
            Unix User Id: 0
            Unix Group Id: 0
            Unix Mode Bits: 777
        Unix Mode Bits in Text: rwxrwxrwx
            ACLs: NTFS Security Descriptor
            Control:0xbf14
            Owner:BUILTIN\Administrators
            Group:BUILTIN\Administrators

= Manage file access using SMB

= Use local users and groups for authentication and authorization

= How ONTAP uses local users and groups

= Local users and groups concepts

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You should know what local users and groups are, and some basic information about them, before determining whether to configure and use local users and groups in your environment.

- **Local user**

A user account with a unique security identifier (SID) that has visibility only on the storage virtual machine (SVM) on which it is created. Local user accounts have a set of attributes, including user name and SID. A local user account authenticates locally on the CIFS server using NTLM authentication.

User accounts have several uses:

- Used to grant *User Rights Management* privileges to a user.
- Used to control share-level and file-level access to file and folder resources that the SVM owns.

- **Local group**

A group with a unique SID has visibility only on the SVM on which it is created. Groups contain a set of members. Members can be local users, domain users, domain groups, and domain machine accounts. Groups can be created, modified, or deleted.

Groups have several uses:

- Used to grant *User Rights Management* privileges to its members.
- Used to control share-level and file-level access to file and folder resources that the SVM owns.

- **Local domain**

A domain that has local scope, which is bounded by the SVM. The local domain's name is the CIFS server name. Local users and groups are contained within the local domain.

- **Security identifier (SID)**

A SID is a variable-length numeric value that identifies Windows-style security principals. For example, a typical SID takes the following form: S-1-5-21-3139654847-1303905135-2517279418-123456.

- **NTLM authentication**

A Microsoft Windows security method used to authenticate users on a CIFS server.

- **Cluster replicated database (RDB)**

A replicated database with an instance on each node in a cluster. Local user and group objects are stored in the RDB.

= Reasons for creating local users and local groups

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

There are several reasons for creating local users and local groups on your storage virtual machine (SVM). For example, you can access an SMB server by using a local user account if the domain controllers (DCs) are unavailable, you might want to use local groups to assign privileges, or your SMB server is in a workgroup.

You can create one or more local user accounts for the following reasons:

- Your SMB server is in a workgroup, and domain users are not available.

Local users are required in workgroup configurations.

- You want the ability to authenticate and log in to the SMB server if the domain controllers are unavailable.

Local users can authenticate with the SMB server by using NTLM authentication when the domain controller is down, or when network problems prevent your SMB server from contacting the domain controller.

- You want to assign *User Rights Management* privileges to a local user.

User Rights Management is the ability for an SMB server administrator to control what rights the users and groups have on the SVM. You can assign privileges to a user by assigning the privileges to the user's account, or by making the user a member of a local group that has those privileges.

You can create one or more local groups for the following reasons:

- Your SMB server is in a workgroup, and domain groups are not available.

Local groups are not required in workgroup configurations, but they can be useful for managing access privileges for local workgroup users.

- You want to control access to file and folder resources by using local groups for share and file-access control.
- You want to create local groups with customized *User Rights Management* privileges.

Some built-in user groups have predefined privileges. To assign a customized set of privileges, you can create a local group and assign the necessary privileges to that group. You can then add local users, domain users, and domain groups to the local group.

[How local user authentication works](#)

[What local privileges are](#)

= How local user authentication works

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

Before a local user can access data on a CIFS server, the user must create an authenticated session.

Because SMB is session-based, the identity of the user can be determined just once, when the session is first set up. The CIFS server uses NTLM-based authentication when authenticating local users. Both NTLMv1 and NTLMv2 are supported.

ONTAP uses local authentication under three use cases. Each use case depends on whether the domain portion of the user name (with the DOMAIN\user format) matches the CIFS server's local domain name (the CIFS server name):

- The domain portion matches

Users who provide local user credentials when requesting access to data are authenticated locally on the CIFS server.

- The domain portion does not match

ONTAP attempts to use NTLM authentication with a domain controller in the domain to which the CIFS server belongs. If authentication succeeds, the login is complete. If it does not succeed, what happens next depends on why authentication did not succeed.

For example, if the user exists in Active Directory but the password is invalid or expired, ONTAP does not attempt to use the corresponding local user account on the CIFS server. Instead, authentication fails. There are other cases where ONTAP uses the corresponding local account on the CIFS server, if it exists, for authentication—even though the NetBIOS domain names do not match. For example, if a matching domain account exists but it is disabled, ONTAP uses the corresponding local account on the CIFS server for authentication.

- The domain portion is not specified

ONTAP first attempts authentication as a local user. If authentication as a local user fails, then ONTAP authenticates the user with a domain controller in the domain to which the CIFS server belongs.

After local or domain user authentication is completed successfully, ONTAP constructs a complete user access token, which takes into account local group membership and privileges.

For more information about NTLM authentication for local users, see the Microsoft Windows documentation.

Related information

[Enabling or disabling local user authentication](#)

= How user access tokens are constructed

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

When a user maps a share, an authenticated SMB session is established and a user access token is constructed that contains information about the user, the user's group membership and cumulative privileges, and the mapped UNIX user.

Unless the functionality is disabled, local user and group information is also added to the user access token. The way access tokens are constructed depends on whether the login is for a local user or an Active Directory domain user:

- Local user login

Although local users can be members of different local groups, local groups cannot be members of other local groups. The local user access token is composed of a union of all privileges assigned to groups to which a particular local user is a member.

- Domain user login

When a domain user logs in, ONTAP obtains a user access token that contains the user SID and SIDs for all the domain groups to which the user is a member. ONTAP uses the union of the domain user access token with the access token provided by local memberships of the user's domain groups (if any), as well as any direct privileges assigned to the domain user or any of its domain group memberships.

For both local and domain user login, the Primary Group RID is also set for the user access token. The

default RID is Domain Users (RID 513). You cannot change the default.

The Windows-to-UNIX and UNIX-to-Windows name mapping process follows the same rules for both local and domain accounts.

There is no implied, automatic mapping from a UNIX user to a local account. If this is required, an explicit mapping rule must be specified using the existing name mapping commands.

= Guidelines for using SnapMirror on SVMs that contain local groups

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You should be aware of the guidelines when you configure SnapMirror on volumes owned by SVMs that contain local groups.

You cannot use local groups in ACEs applied to files, directories, or shares that are replicated by SnapMirror to another SVM. If you use the SnapMirror feature to create a DR mirror to a volume on another SVM and the volume has an ACE for a local group, the ACE is not valid on the mirror. If data is replicated to a different SVM, the data is effectively crossing into a different local domain. The permissions granted to local users and groups are valid only within the scope of the SVM on which they were originally created.

= What happens to local users and groups when deleting CIFS servers

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The default set of local users and groups is created when a CIFS server is created, and they are associated with the storage virtual machine (SVM) hosting the CIFS server. SVM administrators can create local users and groups at any time. You need to be aware of what happens to local users and groups when you delete the CIFS server.

Local users and groups are associated with SVMs; therefore, they are not deleted when CIFS servers are deleted due to security considerations. Although local users and groups are not deleted when the CIFS server is deleted, they are hidden. You cannot view or manage local users and groups until you re-create a CIFS server on the SVM.

The CIFS server administrative status does not affect visibility of local users or groups.

= How you can use Microsoft Management Console with local users and groups

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can view information about local users and groups from the Microsoft Management Console. With this release of ONTAP, you cannot perform other management tasks for local users and groups from the Microsoft Management Console.

= Guidelines for reverting

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you plan to revert the cluster to an ONTAP release that does not support local users and groups and local users and groups are being used to manage file access or user rights, you must be aware of certain considerations.

- Due to security reasons, information about configured local users, groups, and privileges are not deleted when ONTAP is reverted to a version that does not support local users and groups functionality.
- Upon a revert to a prior major version of ONTAP, ONTAP does not use local users and groups during authentication and credential creation.
- Local users and groups are not removed from file and folder ACLs.
- File access requests that depend on access being granted because of permissions granted to local users or groups are denied.

To allow access, you must reconfigure file permissions to allow access based on domain objects instead of local user and group objects.

= What local privileges are

= List of supported privileges

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ONTAP has a predefined set of supported privileges. Certain predefined local groups have some of these privileges added to them by default. You can also add or remove privileges from the predefined groups or create new local users or groups and add privileges to the groups that you created or to existing domain users and groups.

The following table lists the supported privileges on the storage virtual machine (SVM) and provides a list of BUILTIN groups with assigned privileges:

Privilege name	Default security setting	Description
SeTcbPrivilege	None	Act as part of the operating system
SeBackupPrivilege	BUILTIN\Administrators, BUILTIN\Backup Operators	Back up files and directories, overriding any ACLs
SeRestorePrivilege	BUILTIN\Administrators, BUILTIN\Backup Operators	Restore files and directories, overriding any ACLs Set any valid user or group SID as the file owner

Privilege name	Default security setting	Description
SeTakeOwnershipPrivilege	BUILTIN\Administrators	Take ownership of files or other objects
SeSecurityPrivilege	BUILTIN\Administrators	Manage auditingThis includes viewing, dumping, and clearing the security log.
SeChangeNotifyPrivilege	BUILTIN\Administrators, BUILTIN\Backup Operators, BUILTIN\Power Users, BUILTIN\Users, Everyone	Bypass traverse checkingUsers with this privilege are not required to have traverse (x) permissions to traverse folders, symlinks, or junctions.

= Assign privileges

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can assign privileges directly to local users or domain users. Alternatively, you can assign users to local groups whose assigned privileges match the capabilities that you want those users to have.

- You can assign a set of privileges to a group that you create.

You then add a user to the group that has the privileges that you want that user to have.

- You can also assign local users and domain users to predefined groups whose default privileges match the privileges that you want to grant to those users.

Related information

[Adding privileges to local or domain users or groups](#)

[Removing privileges from local or domain users or groups](#)

[Resetting privileges for local or domain users and groups](#)

= Guidelines for using BUILTIN groups and the local administrator account

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

There are certain guidelines you should keep in mind when you use BUILTIN groups and the local administrator account. For example, you can rename the local

administrator account, but you cannot delete this account.

- The Administrator account can be renamed but cannot be deleted.
- The Administrator account cannot be removed from the BUILTIN\Administrators group.
- BUILTIN groups can be renamed but cannot be deleted.

After the BUILTIN group is renamed, another local object can be created with the well-known name; however, the object is assigned a new RID.

- There is no local Guest account.

[Predefined BUILTIN groups and default privileges](#)

= Requirements for local user passwords

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

By default, local user passwords must meet complexity requirements. The password complexity requirements are similar to the requirements defined in the Microsoft Windows *Local security policy*.

The password must meet the following criteria:

- Must be at least six characters in length
- Must not contain the user account name
- Must contain characters from at least three of the following four categories:
 - English uppercase characters (A through Z)
 - English lowercase characters (a through z)
 - Base 10 digits (0 through 9)
 - Special characters:
~ ! @ # \$ % ^ & * _ - + = ` \ | () [] : " ' < > , . ? /

= Predefined BUILTIN groups and default privileges

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can assign membership of a local user or domain user to a predefined set of BUILTIN groups provided by ONTAP. Predefined groups have predefined privileges

assigned.

The following table describes the predefined groups:

Predefined BUILTIN group	Default privileges
BUILTIN\Administrators RID 544 When first created, the local Administrator account, with a RID of 500, is automatically made a member of this group. When the storage virtual machine (SVM) is joined to a domain, the domain\Domain Admins group is added to the group. If the SVM leaves the domain, the domain\Domain Admins group is removed from the group.	<ul style="list-style-type: none">• SeBackupPrivilege• SeRestorePrivilege• SeSecurityPrivilege• SeTakeOwnershipPrivilege• SeChangeNotifyPrivilege
BUILTIN\Power Users RID 547 When first created, this group does not have any members. Members of this group have the following characteristics: <ul style="list-style-type: none">• Can create and manage local users and groups.• Cannot add themselves or any other object to the BUILTIN\Administrators group.	SeChangeNotifyPrivilege
BUILTIN\Backup Operators RID 551 When first created, this group does not have any members. Members of this group can override read and write permissions on files or folders if they are opened with backup intent.	<ul style="list-style-type: none">• SeBackupPrivilege• SeRestorePrivilege• SeChangeNotifyPrivilege
BUILTIN\Users RID 545 When first created, this group does not have any members (besides the implied Authenticated Users special group). When the SVM is joined to a domain, the domain\Domain Users group is added to this group. If the SVM leaves the domain, the domain\Domain Users group is removed from this group.	SeChangeNotifyPrivilege
Everyone SID S-1-1-0 This group includes all users, including guests (but not anonymous users). This is an implied group with an implied membership.	SeChangeNotifyPrivilege

= Enable or disable local users and groups functionality

= Enable or disable local users and groups functionality overview

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

Before you can use local users and groups for access control of NTFS security-style data, local user and group functionality must be enabled. Additionally, if you want to use local users for SMB authentication, the local user authentication functionality must be enabled.

Local users and groups functionality and local user authentication are enabled by default. If they are not enabled, you must enable them before you can configure and use local users and groups. You can disable local users and groups functionality at any time.

In addition to explicitly disabling local user and group functionality, ONTAP disables local user and group functionality if any node in the cluster is reverted to an ONTAP release that does not support the functionality. Local user and group functionality is not enabled until all nodes in the cluster are running a version of ONTAP that supports it.

= Enable or disable local users and groups

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

You can enable or disable local users and groups for SMB access on storage virtual machines (SVMs). Local users and groups functionality is enabled by default.

About this task

You can use local users and groups when configuring SMB share and NTFS file permissions and can optionally use local users for authentication when creating an SMB connection. To use local users for authentication, you must also enable the local users and groups authentication option.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Perform one of the following actions:

If you want local users and groups to be...	Enter the command...
Enabled	vserver cifs options modify -vserver <i>vserver_name</i> -is-local-users-and-groups-enabled true
Disabled	vserver cifs options modify -vserver <i>vserver_name</i> -is-local-users-and-groups-enabled false

3. Return to the admin privilege level: `set -privilege admin`

Example

The following example enables local users and groups functionality on SVM vs1:

```
cluster1::> set -privilege advanced
Warning: These advanced commands are potentially dangerous; use them
only when directed to do so by technical support personnel.
Do you wish to continue? (y or n): y

cluster1::*> vserver cifs options modify -vserver vs1 -is-local-users
-and-groups-enabled true

cluster1::*> set -privilege admin
```

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can enable or disable local user authentication for SMB access on storage virtual machines (SVMs). The default is to allow local user authentication, which is useful when the SVM cannot contact a domain controller or if you choose not to use domain-level access controls.

Before you begin

Local users and groups functionality must be enabled on the CIFS server.

About this task

You can enable or disable local user authentication at any time. If you want to use local users for authentication when creating an SMB connection, you must also enable the CIFS server's local users and groups option.

Steps

1. Set the privilege level to advanced: set -privilege advanced
2. Perform one of the following actions:

If you want local authentication to be...	Enter the command...
Enabled	vserver cifs options modify -vserver <i>vserver_name</i> -is-local-auth-enabled true
Disabled	vserver cifs options modify -vserver <i>vserver_name</i> -is-local-auth-enabled false

3. Return to the admin privilege level: set -privilege admin

Example

The following example enables local user authentication on SVM vs1:

```
cluster1::>set -privilege advanced
Warning: These advanced commands are potentially dangerous; use them
only when directed to do so by technical support personnel.
Do you wish to continue? (y or n): y

cluster1::*> vserver cifs options modify -vserver vs1 -is-local-auth
-enabled true

cluster1::*> set -privilege admin
```

[Enabling or disabling local users and groups](#)

= Manage local user accounts

= Modify local user accounts

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can modify a local user account if you want to change an existing user's full name or description, and if you want to enable or disable the user account. You can also rename a local user account if the user's name is compromised or if a name change is needed for administrative purposes.

If you want to...	Enter the command...
Modify the local user's full name	vserver cifs users-and-groups local-user modify -vserver <i>vserver_name</i> -user-name <i>user_name</i> -full-name <i>text</i> If the full name contains a space, then it must be enclosed within double quotation marks.
Modify the local user's description	vserver cifs users-and-groups local-user modify -vserver <i>vserver_name</i> -user-name <i>user_name</i> -description <i>text</i> If the description contains a space, then it must be enclosed within double quotation marks.
Enable or disable the local user account	vserver cifs users-and-groups local-user modify -vserver <i>vserver_name</i> -user-name <i>user_name</i> -is-account -disabled {true false}
Rename the local user account	vserver cifs users-and-groups local-user rename -vserver <i>vserver_name</i> -user-name <i>user_name</i> -new-user-name <i>new_user_name</i> When renaming a local user, the new user name must remain associated with the same CIFS server as the old user name.

Example

The following example renames the local user “CIFS_SERVER\sue” to “CIFS_SERVER\sue_new” on storage virtual machine (SVM, formerly known as Vserver) vs1:

```
cluster1::> vserver cifs users-and-groups local-user rename -user-name CIFS_SERVER\sue -new-user-name CIFS_SERVER\sue_new -vserver vs1
```

= Enable or disable local user accounts

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You enable a local user account if you want the user to be able to access data contained in the storage virtual machine (SVM) over an SMB connection. You can also disable a local user account if you do not want that user to access SVM data over SMB.

About this task

You enable a local user by modifying the user account.

Step

1. Perform the appropriate action:

If you want to...	Enter the command...
Enable the user account	vserver cifs users-and-groups local-user modify -vserver <i>vserver_name</i> -user-name <i>user_name</i> -is-account -disabled false
Disable the user account	vserver cifs users-and-groups local-user modify -vserver <i>vserver_name</i> -user-name <i>user_name</i> -is-account -disabled true

= Change local user account passwords

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can change a local user's account password. This can be useful if the user's password is compromised or if the user has forgotten the password.

Step

1. Change the password by performing the appropriate action: vserver cifs users-and-groups local-user set-password -vserver *vserver_name* -user-name *user_name*

Example

The following example sets the password for the local user "CIFS_SERVER\sue" associated with storage virtual machine (SVM, formerly known as Vserver) vs1:

```
cluster1::> vserver cifs users-and-groups local-user set-password -user-name CIFS_SERVER\sue -vserver vs1
```

Enter the new password:

Confirm the new password:

Related information

[Enabling or disabling required password complexity for local SMB users](#)

[Displaying information about CIFS server security settings](#)

= Display information about local users

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can display a list of all local users in a summary form. If you want to determine which account settings are configured for a specific user, you can display detailed account information for that user as well as the account information for multiple

users. This information can help you determine if you need to modify a user's settings, and also to troubleshoot authentication or file access issues.

About this task

Information about a user's password is never displayed.

Step

1. Perform one of the following actions:

If you want to...	Enter the command...
Display information about all users on the storage virtual machine (SVM)	vserver cifs users-and-groups local-user show -vserver vserver_name
Display detailed account information for a user	vserver cifs users-and-groups local-user show -instance -vserver vserver_name -user-name user_name

There are other optional parameters that you can choose when you run the command. See the man page for more information.

Example

The following example displays information about all local users on SVM vs1:

```
cluster1::> vserver cifs users-and-groups local-user show -vserver vs1
Vserver   User Name          Full Name      Description
-----
vs1      CIFS_SERVER\Administrator    James Smith    Built-in
administrator account
vs1      CIFS_SERVER\sue            Sue Jones
```

= Display information about group memberships for local users

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can display information about which local groups that a local user belongs to. You can use this information to determine what access the user should have to files and folders. This information can be useful in determining what access rights the user should have to files and folders or when troubleshooting file access issues.

About this task

You can customize the command to display only the information that you want to see.

Step

1. Perform one of the following actions:

If you want to...	Enter the command...
Display local user membership information for a specified local user	vserver cifs users-and-groups local-user show-membership -user-name <i>user_name</i>
Display local user membership information for the local group of which this local user is a member	vserver cifs users-and-groups local-user show-membership -membership <i>group_name</i>
Display user membership information for local users that are associated with a specified storage virtual machine (SVM)	vserver cifs users-and-groups local-user show-membership -vserver <i>vserver_name</i>
Display detailed information for all local users on a specified SVM	vserver cifs users-and-groups local-user show-membership -instance -vserver <i>vserver_name</i>

Example

The following example displays the membership information for all local users on SVM vs1; user “CIFS_SERVER\Administrator” is a member of the “BUILTIN\Administrators” group, and “CIFS_SERVER\sue” is a member of “CIFS_SERVER\g1” group:

```
cluster1::> vserver cifs users-and-groups local-user show-membership
-vserver vs1
Vserver      User Name          Membership
-----
vs1          CIFS_SERVER\Administrator    BUILTIN\Administrators
              CIFS_SERVER\sue           CIFS_SERVER\g1
```

= Delete local user accounts

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

You can delete local user accounts from your storage virtual machine (SVM) if they are no longer needed for local SMB authentication to the CIFS server or for determining access rights to data contained on your SVM.

About this task

Keep the following in mind when deleting local users:

- The file system is not altered.

Windows Security Descriptors on files and directories that refer to this user are not adjusted.

- All references to local users are removed from the membership and privileges databases.

- Standard, well-known users such as Administrator cannot be deleted.

Steps

1. Determine the name of the local user account that you want to delete: `vserver cifs users-and-groups local-user show -vserver vserver_name`
2. Delete the local user: `vserver cifs users-and-groups local-user delete -vserver vserver_name -user-name username_name`
3. Verify that the user account is deleted: `vserver cifs users-and-groups local-user show -vserver vserver_name`

Example

The following example deletes the local user “CIFS_SERVER\sue” associated with SVM vs1:

```
cluster1::> vserver cifs users-and-groups local-user show -vserver vs1
Vserver      User Name          Full Name      Description
-----
```

vs1	CIFS_SERVER\Administrator	James Smith	Built-in administrator account
vs1	CIFS_SERVER\sue	Sue Jones	

```
cluster1::> vserver cifs users-and-groups local-user delete -vserver vs1 -user-name CIFS_SERVER\sue
```

```
cluster1::> vserver cifs users-and-groups local-user show -vserver vs1
Vserver      User Name          Full Name      Description
-----
```

vs1	CIFS_SERVER\Administrator	James Smith	Built-in administrator account
-----	---------------------------	-------------	--------------------------------

= Manage local groups

= Modify local groups

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can modify existing local groups by changing the description for an existing local group or by renaming the group.

If you want to...	Use the command...
Modify the local group description	<code>vserver cifs users-and-groups local-group modify -vserver vserver_name -group-name group_name -description text</code> If the description contains a space, then it must be enclosed within double quotation marks.

If you want to...	Use the command...
Rename the local group	vserver cifs users-and-groups local-group rename -vserver <i>vserver_name</i> -group-name <i>group_name</i> -new-group-name <i>new_group_name</i>

Examples

The following example renames the local group “CIFS_SERVER\engineering” to “CIFS_SERVER\engineering_new”:

```
cluster1::> vserver cifs users-and-groups local-group rename -vserver
vs1 -group-name CIFS_SERVER\engineering -new-group-name
CIFS_SERVER\engineering_new
```

The following example modifies the description of the local group “CIFS_SERVER\engineering”:

```
cluster1::> vserver cifs users-and-groups local-group modify -vserver
vs1 -group-name CIFS_SERVER\engineering -description "New Description"
```

= Display information about local groups
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can display a list of all local groups configured on the cluster or on a specified storage virtual machine (SVM). This information can be useful when troubleshooting file-access issues to data contained on the SVM or user-rights (privilege) issues on the SVM.

Step

1. Perform one of the following actions:

If you want information about...	Enter the command...
All local groups on the cluster	vserver cifs users-and-groups local-group show
All local groups on the SVM	vserver cifs users-and-groups local-group show -vserver <i>vserver_name</i>

There are other optional parameters that you can choose when you run this command. See the man page for more information.

Example

The following example displays information about all local groups on SVM vs1:

```
cluster1::> vserver cifs users-and-groups local-group show -vserver vs1
Vserver      Group Name          Description
-----      -----
vs1         BUILTIN\Administrators    Built-in Administrators group
vs1         BUILTIN\Backup Operators   Backup Operators group
vs1         BUILTIN\Power Users       Restricted administrative
privileges
vs1         BUILTIN\Users            All users
vs1         CIFS_SERVER\engineering
vs1         CIFS_SERVER\sales
```

= Manage local group membership

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

You can manage local group membership by adding and removing local or domain users, or adding and removing domain groups. This is useful if you want to control access to data based on access controls placed on the group or if you want users to have privileges associated with that group.

About this task

Guidelines for adding members to a local group:

- You cannot add users to the special *Everyone* group.
- The local group must exist before you can add a user to it.
- The user must exist before you can add the user to a local group.
- You cannot add a local group to another local group.
- To add a domain user or group to a local group, Data ONTAP must be able to resolve the name to a SID.

Guidelines for removing members from a local group:

- You cannot remove members from the special *Everyone* group.
- The group from which you want to remove a member must exist.
- ONTAP must be able to resolve the names of members that you want to remove from the group to a corresponding SID.

Step

1. Add or remove a member in a group.

If you want to...	Then use the command...
Add a member to a group	vserver cifs users-and-groups local-group add-members -vserver _vserver_name_ -group-name _group_name_ -member-names name [, . . .] You can specify a comma-delimited list of local users, domain users, or domain groups to add to the specified local group.
Remove a member from a group	vserver cifs users-and-groups local-group remove-members -vserver _vserver_name_ -group-name _group_name_ -member-names name [, . . .] You can specify a comma-delimited list of local users, domain users, or domain groups to remove from the specified local group.

The following example adds a local user “SMB_SERVER\sue” and a domain group “AD_DOM\dom_eng” to the local group “SMB_SERVER\engineering” on SVM vs1:

```
cluster1::> vserver cifs users-and-groups local-group add-members
-vserver vs1 -group-name SMB_SERVER\engineering -member-names
SMB_SERVER\sue,AD_DOMAIN\dom_eng
```

The following example removes the local users “SMB_SERVER\sue” and “SMB_SERVER\james” from the local group “SMB_SERVER\engineering” on SVM vs1:

```
cluster1::> vserver cifs users-and-groups local-group remove-members
-vserver vs1 -group-name SMB_SERVER\engineering -member-names
SMB_SERVER\sue,SMB_SERVER\james
```

Related information

[Displaying information about members of local groups](#)

= Display information about members of local groups

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can display a list of all members of local groups configured on the cluster or on a specified storage virtual machine (SVM). This information can be useful when troubleshooting file-access issues or user-rights (privilege) issues.

Step

1. Perform one of the following actions:

If you want to display information about...	Enter the command...
Members of all local groups on the cluster	vserver cifs users-and-groups local-group show-members
Members of all local groups on the SVM	vserver cifs users-and-groups local-group show-members -vserver <i>vserver_name</i>

Example

The following example displays information about members of all local groups on SVM vs1:

```
cluster1::> vserver cifs users-and-groups local-group show-members
-vserver vs1
Vserver      Group Name          Members
-----
vs1          BUILTIN\Administrators
                           CIFS_SERVER\Administrator
                           AD_DOMAIN\Domain Admins
                           AD_DOMAIN\dom_grpl
                           AD_DOMAIN\Domain Users
                           AD_DOMAIN\dom_usr1
                           CIFS_SERVER\james
                           BUILTIN\Users
                           CIFS_SERVER\engineering
```

= Delete a local group

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can delete a local group from the storage virtual machine (SVM) if it is no longer needed for determining access rights to data associated with that SVM or if it is no longer needed for assigning SVM user rights (privileges) to group members.

About this task

Keep the following in mind when deleting local groups:

- The file system is not altered.

Windows Security Descriptors on files and directories that refer to this group are not adjusted.

- If the group does not exist, an error is returned.
- The special *Everyone* group cannot be deleted.
- Built-in groups such as *BUILTIN\Administrators* *BUILTIN\Users* cannot be deleted.

Steps

1. Determine the name of the local group that you want to delete by displaying the list of local groups on the SVM: `vserver cifs users-and-groups local-group show -vserver vserver_name`

2. Delete the local group: `vserver cifs users-and-groups local-group delete -vserver vserver_name -group-name group_name`
3. Verify that the group is deleted: `vserver cifs users-and-groups local-user show -vserver vserver_name`

Example

The following example deletes the local group “CIFS_SERVER\sales” associated with SVM vs1:

```
cluster1::> vserver cifs users-and-groups local-group show -vserver vs1
Vserver      Group Name          Description
-----
vs1         BUILTIN\Administrators    Built-in Administrators group
vs1         BUILTIN\Backup Operators   Backup Operators group
vs1         BUILTIN\Power Users       Restricted administrative
privileges
vs1         BUILTIN\Users            All users
vs1         CIFS_SERVER\engineering
vs1         CIFS_SERVER\sales

cluster1::> vserver cifs users-and-groups local-group delete -vserver
vs1 -group-name CIFS_SERVER\sales

cluster1::> vserver cifs users-and-groups local-group show -vserver vs1
Vserver      Group Name          Description
-----
vs1         BUILTIN\Administrators    Built-in Administrators group
vs1         BUILTIN\Backup Operators   Backup Operators group
vs1         BUILTIN\Power Users       Restricted administrative
privileges
vs1         BUILTIN\Users            All users
vs1         CIFS_SERVER\engineering
```

= Update domain user and group names in local databases

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can add domain users and groups to a CIFS server’s local groups. These domain objects are registered in local databases on the cluster. If a domain object is renamed, the local databases must be manually updated.

About this task

You must specify the name of the storage virtual machine (SVM) on which you want to update domain names.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`

2. Perform the appropriate action:

If you want to update domain users and groups and...	Use this command...
Display domain users and groups that successfully updated and that failed to update	<code>vserver cifs users-and-groups update-names -vserver vserver_name</code>
Display domain users and groups that successfully updated	<code>vserver cifs users-and-groups update-names -vserver vserver_name -display-failed-only false</code>
Display only the domain users and groups that fail to update	<code>vserver cifs users-and-groups update-names -vserver vserver_name -display-failed-only true</code>
Suppress all status information about updates	<code>vserver cifs users-and-groups update-names -vserver vserver_name -suppress-all-output true</code>

3. Return to the admin privilege level: `set -privilege admin`

Example

The following example updates the names of domain users and groups associated with storage virtual machine (SVM, formerly known as Vserver) vs1. For the last update, there is a dependent chain of names that needs to be updated:

```

cluster1::> set -privilege advanced
Warning: These advanced commands are potentially dangerous; use them
only when directed to do so by technical support personnel.
Do you wish to continue? (y or n): y

cluster1::*> vserver cifs users-and-groups update-names -vserver vs1

Vserver:           vs1
SID:              S-1-5-21-123456789-234565432-987654321-12345

                           to name "dom_user7"; also updated SID "S-1-5-21-
123456789-234565432-987654321-123460"
                           to name "dom_user8"

```

The command completed successfully. 7 Active Directory objects have been updated.

```
cluster1::*> set -privilege admin
```

= Manage local privileges

= Add privileges to local or domain users or groups
:icons: font
:relative_path: ./smb-admin/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/ ./smb-admin/..../media/
```

You can manage user rights for local or domain users or groups by adding privileges. The added privileges override the default privileges assigned to any of these objects. This provides enhanced security by allowing you to customize what privileges a user or group has.

Before you begin

The local or domain user or group to which privileges will be added must already exist.

About this task

Adding a privilege to an object overrides the default privileges for that user or group. Adding a privilege does not remove previously added privileges.

You must keep the following in mind when adding privileges to local or domain users or groups:

- You can add one or more privileges.
- When adding privileges to a domain user or group, ONTAP might validate the domain user or group by contacting the domain controller.

The command might fail if ONTAP is unable to contact the domain controller.

Steps

1. Add one or more privileges to a local or domain user or group: vserver cifs users-and-groups privilege add-privilege -vserver *vserver_name* -user-or-group-name *name* -privileges *privilege* [,,...]
2. Verify that the desired privileges are applied to the object: vserver cifs users-and-groups privilege show -vserver *vserver_name* -user-or-group-name *name*

Example

The following example adds the privileges “SeTcbPrivilege” and “SeTakeOwnershipPrivilege” to the user “CIFS_SERVER\sue” on storage virtual machine (SVM, formerly known as Vserver) vs1:

```
cluster1::> vserver cifs users-and-groups privilege add-privilege  
-vserver vs1 -user-or-group-name CIFS_SERVER\sue -privileges  
SeTcbPrivilege,SeTakeOwnershipPrivilege  
  
cluster1::> vserver cifs users-and-groups privilege show -vserver vs1  
Vserver      User or Group Name      Privileges  
-----  
vs1          CIFS_SERVER\sue        SeTcbPrivilege  
                           SeTakeOwnershipPrivilege
```

= Remove privileges from local or domain users or groups

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/ ./smb-admin/..../media/

You can manage user rights for local or domain users or groups by removing privileges. This provides enhanced security by allowing you to customize the maximum privileges that users and groups have.

Before you begin

The local or domain user or group from which privileges will be removed must already exist.

About this task

You must keep the following in mind when removing privileges from local or domain users or groups:

- You can remove one or more privileges.
- When removing privileges from a domain user or group, ONTAP might validate the domain user or group by contacting the domain controller.

The command might fail if ONTAP is unable to contact the domain controller.

Steps

1. Remove one or more privileges from a local or domain user or group: `vserver cifs users-and-groups privilege remove-privilege -vserver _vserver_name_ -user-or-group-name _name_ -privileges _privilege_[,...]`
2. Verify that the desired privileges have been removed from the object: `vserver cifs users-and-groups privilege show -vserver vserver_name -user-or-group-name name`

Example

The following example removes the privileges “SeTcbPrivilege” and “SeTakeOwnershipPrivilege” from the user “CIFS_SERVER\sue” on storage virtual machine (SVM, formerly known as Vserver) vs1:

```
cluster1::> vserver cifs users-and-groups privilege show -vserver vs1
Vserver      User or Group Name      Privileges
-----
vs1          CIFS_SERVER\sue        SeTcbPrivilege
                         SeTakeOwnershipPrivilege

cluster1::> vserver cifs users-and-groups privilege remove-privilege
-vserver vs1 -user-or-group-name CIFS_SERVER\sue -privileges
SeTcbPrivilege,SeTakeOwnershipPrivilege

cluster1::> vserver cifs users-and-groups privilege show -vserver vs1
Vserver      User or Group Name      Privileges
-----
vs1          CIFS_SERVER\sue        -
```

= Reset privileges for local or domain users and groups

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can reset privileges for local or domain users and groups. This can be useful when you have made modifications to privileges for a local or domain user or group and those modifications are no longer wanted or needed.

About this task

Resetting privileges for a local or domain user or group removes any privilege entries for that object.

Steps

1. Reset the privileges on a local or domain user or group: `vserver cifs users-and-groups privilege reset-privilege -vserver vserver_name -user-or-group-name name`
2. Verify that the privileges are reset on the object: `vserver cifs users-and-groups privilege show -vserver vserver_name -user-or-group-name name`

Examples

The following example resets the privileges on the user “CIFS_SERVER\sue” on storage virtual machine (SVM, formerly known as Vserver) vs1. By default, normal users do not have privileges associated with their accounts:

```
cluster1::> vserver cifs users-and-groups privilege show
Vserver      User or Group Name      Privileges
-----
vs1          CIFS_SERVER\sue        SeTcbPrivilege
                           SeTakeOwnershipPrivilege

cluster1::> vserver cifs users-and-groups privilege reset-privilege
-vserver vs1 -user-or-group-name CIFS_SERVER\sue

cluster1::> vserver cifs users-and-groups privilege show
This table is currently empty.
```

The following example resets the privileges for the group “BUILTIN\Administrators”, effectively removing the privilege entry:

```
cluster1::> vserver cifs users-and-groups privilege show
Vserver      User or Group Name      Privileges
-----
vs1          BUILTIN\Administrators   SeRestorePrivilege
                           SeSecurityPrivilege
                           SeTakeOwnershipPrivilege

cluster1::> vserver cifs users-and-groups privilege reset-privilege
-vserver vs1 -user-or-group-name BUILTIN\Administrators

cluster1::> vserver cifs users-and-groups privilege show
This table is currently empty.
```

= Display information about privilege overrides
 :icons: font
 :relative_path: ./smb-admin/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/./media/

You can display information about custom privileges assigned to domain or local user accounts or groups. This information helps you determine whether the desired user rights are applied.

Step

1. Perform one of the following actions:

If you want to display information about...	Enter this command...
Custom privileges for all domain and local users and groups on the storage virtual machine (SVM)	vserver cifs users-and-groups privilege show -vserver vserver_name
Custom privileges for a specific domain or local user and group on the SVM	vserver cifs users-and-groups privilege show -vserver vserver_name -user-or-group-name name

There are other optional parameters that you can choose when you run this command. See the man page for more information.

Example

The following command displays all privileges explicitly associated with local or domain users and groups for SVM vs1:

```
cluster1::> vserver cifs users-and-groups privilege show -vserver vs1
Vserver      User or Group Name      Privileges
-----
vs1          BUILTIN\Administrators  SeTakeOwnershipPrivilege
                         SeRestorePrivilege
vs1          CIFS_SERVER\sue        SeTcbPrivilege
                         SeTakeOwnershipPrivilege
```

= Configure bypass traverse checking

= Configure bypass traverse checking overview
 :icons: font
 :relative_path: ./smb-admin/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/./media/

Bypass traverse checking is a user right (also known as a *privilege*) that determines whether a user can traverse all the directories in the path to a file even if the user does not have permissions on the traversed directory. You should understand what happens when allowing or disallowing bypass traverse checking, and how to

configure bypass traverse checking for users on storage virtual machines (SVMs).

== What happens when allowing or disallowing bypass traverse checking

- If allowed, when a user attempts to access a file, ONTAP does not check the traverse permission for the intermediate directories when determining whether to grant or deny access to the file.
- If disallowed, ONTAP checks the traverse (execute) permission for all directories in the path to the file.

If any of the intermediate directories do not have the “X” (traverse permission), ONTAP denies access to the file.

== Configure bypass traverse checking

You can configure bypass traverse checking by using the ONTAP CLI or by configuring Active Directory group policies with this user right.

The `SeChangeNotifyPrivilege` privilege controls whether users are allowed to bypass traverse checking.

- Adding it to local SMB users or groups on the SVM or to domain users or groups allows bypass traverse checking.
- Removing it from local SMB users or groups on the SVM or from domain users or groups disallows bypass traverse checking.

By default, the following BUILTIN groups on the SVM have the right to bypass traverse checking:

- BUILTIN\Administrators
- BUILTIN\Power Users
- BUILTIN\Backup Operators
- BUILTIN\Users
- Everyone

If you do not want to allow members of one of these groups to bypass traverse checking, you must remove this privilege from the group.

You must keep the following in mind when configuring bypass traverse checking for local SMB users and groups on the SVM by using the CLI:

- If you want to allow members of a custom local or domain group to bypass traverse checking, you must add the `SeChangeNotifyPrivilege` privilege to that group.
- If you want to allow an individual local or domain user to bypass traverse checking and that user is not a member of a group with that privilege, you can add the `SeChangeNotifyPrivilege` privilege to that user account.
- You can disable bypass traverse checking for local or domain users or groups by removing the `SeChangeNotifyPrivilege` privilege at any time.

To disable bypass travers checking for specified local or domain users or groups, you must also remove the `SeChangeNotifyPrivilege` privilege from the Everyone group.

= Allow users or groups to bypass directory traverse checking

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you want a user to be able traverse all the directories in the path to a file even if the user does not have permissions on a traversed directory, you can add the SeChangeNotifyPrivilege privilege to local SMB users or groups on storage virtual machines (SVMs). By default, users are able to bypass directory traverse checking.

Before you begin

- A SMB server must be exist on the SVM.
- The local users and groups SMB server option must be enabled.
- The local or domain user or group to which the SeChangeNotifyPrivilege privilege will be added must already exist.

About this task

When adding privileges to a domain user or group, ONTAP might validate the domain user or group by contacting the domain controller. The command might fail if ONTAP cannot contact the domain controller.

Steps

1. Enable bypass traverse checking by adding the SeChangeNotifyPrivilege privilege to a local or domain user or group: `vserver cifs users-and-groups privilege add-privilege -vserver vserver_name -user-or-group-name name -privileges SeChangeNotifyPrivilege`

The value for the `-user-or-group-name` parameter is a local user or group, or a domain user or group.

2. Verify that the specified user or group has bypass traverse checking enabled: `vserver cifs users-and-groups privilege show -vserver vserver_name -user-or-group-name name`

Example

The following command enables users that belong to the “EXAMPLE\eng” group to bypass directory

traverse checking by adding the SeChangeNotifyPrivilege privilege to the group:

```
cluster1::> vserver cifs users-and-groups privilege add-privilege  
-vserver vs1 -user-or-group-name EXAMPLE\eng -privileges  
SeChangeNotifyPrivilege  
  
cluster1::> vserver cifs users-and-groups privilege show -vserver vs1  
Vserver      User or Group Name      Privileges  
-----  
vs1          EXAMPLE\eng            SeChangeNotifyPrivilege
```

Related information

[Disallowing users or groups from bypassing directory traverse checking](#)

= Disallow users or groups from bypassing directory traverse checking

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you do not want a user to traverse all the directories in the path to a file because the user does not have permissions on the traversed directory, you can remove the SeChangeNotifyPrivilege privilege from local SMB users or groups on storage virtual machines (SVMs).

Before you begin

The local or domain user or group from which privileges will be removed must already exist.

About this task

When removing privileges from a domain user or group, ONTAP might validate the domain user or group by contacting the domain controller. The command might fail if ONTAP cannot contact the domain controller.

Steps

1. Disallow bypass traverse checking: `vserver cifs users-and-groups privilege remove-privilege -vserver vserver_name -user-or-group-name name -privileges SeChangeNotifyPrivilege`

The command removes the SeChangeNotifyPrivilege privilege from the local or domain user or group that you specify with the value for the `-user-or-group-name name` parameter.

2. Verify that the specified user or group has bypass traverse checking disabled: `vserver cifs users-and-groups privilege show -vserver vserver_name -user-or-group-name name`

Example

The following command disallows users that belong to the “EXAMPLE\eng” group from bypassing directory traverse checking:

```

cluster1::> vserver cifs users-and-groups privilege show -vserver vs1
Vserver      User or Group Name      Privileges
-----
vs1          EXAMPLE\eng            SeChangeNotifyPrivilege

cluster1::> vserver cifs users-and-groups privilege remove-privilege
-vserver vs1 -user-or-group-name EXAMPLE\eng -privileges
SeChangeNotifyPrivilege

cluster1::> vserver cifs users-and-groups privilege show -vserver vs1
Vserver      User or Group Name      Privileges
-----
vs1          EXAMPLE\eng            -

```

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

You can display information about file security on files and directories contained within volumes on storage virtual machines (SVMs). You can display information about audit policies on FlexVol volumes. If configured, you can display information about Storage-Level Access Guard and Dynamic Access Control security settings on FlexVol volumes.

--= Displaying information about file security

You can display information about file security applied to data contained within volumes and qtrees (for FlexVol volumes) with the following security styles:

- NTFS
- UNIX
- Mixed

--= Displaying information about audit policies

You can display information about audit policies for auditing access events on FlexVol volumes over the following NAS protocols:

- SMB (all versions)
- NFSv4.x

--= Displaying information about Storage-Level Access Guard (SLAG) security

Storage-Level Access Guard security can be applied on FlexVol volumes and qtree objects with the following security styles:

- NTFS
- Mixed
- UNIX (if a CIFS server is configured on the SVM that contains the volume)

== Displaying information about Dynamic Access Control (DAC) security

Dynamic Access Control security can be applied on an object within a FlexVol volume with the following security styles:

- NTFS
- Mixed (if the object has NTFS effective security)

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can display information about file and directory security on NTFS security-style volumes, including what the security style and effective security styles are, what permissions are applied, and information about DOS attributes. You can use the results to validate your security configuration or to troubleshoot file access issues.

About this task

You must supply the name of the storage virtual machine (SVM) and the path to the data whose file or folder security information you want to display. You can display the output in summary form or as a detailed list.

- Because NTFS security-style volumes and qtrees use only NTFS file permissions and Windows users and groups when determining file access rights, UNIX-related output fields contain display-only UNIX file permission information.
- ACL output is displayed for file and folders with NTFS security.
- Because Storage-Level Access Guard security can be configured on the volume root or qtree, output for a volume or qtree path where Storage-Level Access Guard is configured might display both regular file ACLs and Storage-Level Access Guard ACLs.
- The output also displays information about Dynamic Access Control ACEs if Dynamic Access Control is configured for the given file or directory path.

Step

1. Display file and directory security settings with the desired level of detail:

If you want to display information...	Enter the following command...
In summary form	vserver security file-directory show -vserver <i>vserver_name</i> -path <i>path</i>
With expanded detail	vserver security file-directory show -vserver <i>vserver_name</i> -path <i>path</i> -expand-mask true

Examples

The following example displays the security information about the path /vol4 in SVM vs1:

```
cluster::> vserver security file-directory show -vserver vs1 -path
/vol4

          Vserver: vs1
          File Path: /vol4
          File Inode Number: 64
          Security Style: ntfs
          Effective Style: ntfs

Related information

[Displaying information about file security on mixed security-style volumes](#)

[Displaying information about file security on UNIX security-style volumes](#)

= [Display information about file security on mixed security-style volumes](#)

```
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

You can display information about file and directory security on mixed security-style volumes, including what the security style and effective security styles are, what permissions are applied, and information about UNIX owners and groups. You can use the results to validate your security configuration or to troubleshoot file access issues.

About this task

You must supply the name of the storage virtual machine (SVM) and the path to the data whose file or folder security information you want to display. You can display the output in summary form or as a detailed list.

- Mixed security-style volumes and qtrees can contain some files and folders that use UNIX file permissions, either mode bits or NFSv4 ACLs, and some files and directories that use NTFS file permissions.
- The top level of a mixed security-style volume can have either UNIX or NTFS effective security.
- ACL output is displayed only for file and folders with NTFS or NFSv4 security.

This field is empty for files and directories using UNIX security that have only mode bit permissions applied (no NFSv4 ACLs).

- The owner and group output fields in the ACL output apply only in the case of NTFS security descriptors.
- Because Storage-Level Access Guard security can be configured on a mixed security-style volume or qtree even if the effective security style of the volume root or qtree is UNIX, output for a volume or qtree path where Storage-Level Access Guard is configured might display both UNIX file permissions and Storage-Level Access Guard ACLs.
- If the path entered in the command is to data with NTFS effective security, the output also displays information about Dynamic Access Control ACEs if Dynamic Access Control is configured for the given file or directory path.

Step

1. Display file and directory security settings with the desired level of detail:

If you want to display information...	Enter the following command...
In summary form	vserver security file-directory show -vserver vserver_name -path path
With expanded detail	vserver security file-directory show -vserver vserver_name -path path -expand-mask true

Examples

The following example displays the security information about the path /projects in SVM vs1 in expanded-mask form. This mixed security-style path has UNIX effective security.

```
cluster1::> vserver security file-directory show -vserver vs1 -path  
/projects -expand-mask true  
  
          Vserver: vs1  
          File Path: /projects  
          File Inode Number: 78  
          Security Style: mixed

Related information

[Displaying information about file security on NTFS security-style volumes](#)

[Displaying information about file security on UNIX security-style volumes](#)

= Display information about file security on UNIX security-style volumes

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can display information about file and directory security on UNIX security-style volumes, including what the security styles and effective security styles are, what permissions are applied, and information about UNIX owners and groups. You can use the results to validate your security configuration or to troubleshoot file access issues.

About this task

You must supply the name of the storage virtual machine (SVM) and the path to the data whose file or directory security information you want to display. You can display the output in summary form or as a detailed list.

- UNIX security-style volumes and qtrees use only UNIX file permissions, either mode bits or NFSv4 ACLs when determining file access rights.
- ACL output is displayed only for file and folders with NFSv4 security.

This field is empty for files and directories using UNIX security that have only mode bit permissions applied (no NFSv4 ACLs).

- The owner and group output fields in the ACL output does not apply in the case of NFSv4 security descriptors.

They are only meaningful for NTFS security descriptors.

- Because Storage-Level Access Guard security is supported on a UNIX volume or qtree if a CIFS server is configured on the SVM, the output might contain information about Storage-Level Access Guard security applied to the volume or qtree specified in the `-path` parameter.

Step

1. Display file and directory security settings with the desired level of detail:

If you want to display information...	Enter the following command...
In summary form	<code>vserver security file-directory show -vserver vserver_name -path path</code>
With expanded detail	<code>vserver security file-directory show -vserver vserver_name -path path -expand-mask true</code>

Examples

The following example displays the security information about the path `/home` in SVM `vs1`:

```
cluster1::> vserver security file-directory show -vserver vs1 -path /home
```

```
          Vserver: vs1
          File Path: /home
          File Inode Number: 9590
          Security Style: unix
          Effective Style: unix
          DOS Attributes: 10
          DOS Attributes in Text: ----D---
          Expanded Dos Attributes: -

= Display information about NTFS audit policies on FlexVol volumes using the CLI

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..../media/

You can display information about NTFS audit policies on FlexVol volumes, including what the security styles and effective security styles are, what permissions are applied, and information about system access control lists. You can use the results to validate your security configuration or to troubleshoot auditing issues.

About this task

You must provide the name of the storage virtual machine (SVM) and the path to the files or folders whose audit information you want to display. You can display the output in summary form or as a detailed list.

- NTFS security-style volumes and qtrees use only NTFS system access control lists (SACLs) for audit policies.
- Files and folders in a mixed security-style volume with NTFS effective security can have NTFS audit policies applied to them.

Mixed security-style volumes and qtrees can contain some files and directories that use UNIX file permissions, either mode bits or NFSv4 ACLs, and some files and directories that use NTFS file permissions.

- The top level of a mixed security-style volume can have either UNIX or NTFS effective security and might or might not contain NTFS SACLs.
- Because Storage-Level Access Guard security can be configured on a mixed security-style volume or qtree even if the effective security style of the volume root or qtree is UNIX, the output for a volume or qtree path where Storage-Level Access Guard is configured might display both regular file and folder NFSv4 SACLs and Storage-Level Access Guard NTFS SACLs.
- If the path that is entered in the command is to data with NTFS effective security, the output also displays information about Dynamic Access Control ACEs if Dynamic Access Control is configured for the given file or directory path.
- When displaying security information about files and folders with NTFS effective security, UNIX-related output fields contain display-only UNIX file permission information.

NTFS security-style files and folders use only NTFS file permissions and Windows users and groups when determining file access rights.

- ACL output is displayed only for files and folders with NTFS or NFSv4 security.

This field is empty for files and folders using UNIX security that have only mode bit permissions applied (no NFSv4 ACLs).

- The owner and group output fields in the ACL output apply only in the case of NTFS security descriptors.

Step

1. Display file and directory audit policy settings with the desired level of detail:

= Display information about NFSv4 audit policies on FlexVol volumes using the CLI
:icons: font

```
:relative_path: ./smb-admin/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/
```

You can display information about NFSv4 audit policies on FlexVol volumes using the ONTAP CLI, including what the security styles and effective security styles are, what permissions are applied, and information about system access control lists (SACLs). You can use the results to validate your security configuration or to troubleshoot auditing issues.

About this task

You must supply the name of the storage virtual machine (SVM) and the path to the files or directories whose audit information you want to display. You can display the output in summary form or as a detailed list.

- UNIX security-style volumes and qtrees use only NFSv4 SACLs for audit policies.
- Files and directories in a mixed security-style volume that are of UNIX security style can have NFSv4 audit policies applied to them.

Mixed security-style volumes and qtrees can contain some files and directories that use UNIX file permissions, either mode bits or NFSv4 ACLs, and some files and directories that use NTFS file permissions.

- The top level of a mixed security-style volume can have either UNIX or NTFS effective security and might or might not contain NFSv4 SACLs.
- ACL output is displayed only for file and folders with NTFS or NFSv4 security.

This field is empty for files and folders using UNIX security that have only mode bit permissions applied (no NFSv4 ACLs).

- The owner and group output fields in the ACL output apply only in the case of NTFS security descriptors.
- Because Storage-Level Access Guard security can be configured on a mixed security-style volume or qtree even if the effective security style of the volume root or qtree is UNIX, output for a volume or qtree path where Storage-Level Access Guard is configured might display both regular NFSv4 file and directory SACLs and Storage-Level Access Guard NTFS SACLs.
- Because Storage-Level Access Guard security is supported on a UNIX volume or qtree if a CIFS server is configured on the SVM, the output might contain information about Storage-Level Access Guard security applied to the volume or qtree specified in the `-path` parameter.

Steps

1. Display file and directory security settings with the desired level of detail:

If you want to display information...	Enter the following command...
In summary form	<code>vserver security file-directory show -vserver vserver_name -path path</code>
With expanded detail	<code>vserver security file-directory show -vserver vserver_name -path path -expand-mask true</code>

Examples

The following example displays the security information about the path /lab in SVM vs1. This UNIX security-style path has an NFSv4 SACL.

```
cluster::> vserver security file-directory show -vserver vs1 -path /lab

    Vserver: vs1
    File Path: /lab
    File Inode Number: 288
    Security Style: unix
    Effective Style: unix
    DOS Attributes: 11
    DOS Attributes in Text: ----D--R
    Expanded Dos Attributes: -
        Unix User Id: 0
        Unix Group Id: 0
        Unix Mode Bits: 0
    Unix Mode Bits in Text: -----
        ACLs: NFSV4 Security Descriptor
        Control:0x8014
        SACL - ACEs
            SUCCESSFUL-S-1-520-0-0xf01ff-SA
            FAILED-S-1-520-0-0xf01ff-FA
        DACL - ACEs
            ALLOW-S-1-520-1-0xf01ff
```

= Ways to display information about file security and audit policies

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can use the wildcard character (*) to display information about file security and audit policies of all files and directories under a given path or a root volume.

The wildcard character () **can be used as the last subcomponent of a given directory path below which you want to display information of all files and directories. If you want to display information of a particular file or directory named as “”, then you need to provide the complete path inside double quotes ("")**.

Example

The following command with the wildcard character displays the information about all files and directories below the path /1/ of SVM vs1:

```

cluster::> vserver security file-directory show -vserver vs1 -path /1/*
                                         Vserver: vs1
                                         File Path: /1/1
                                         Security Style: mixed
                                         Effective Style: ntfs
                                         DOS Attributes: 10
                                         DOS Attributes in Text: ----D---
                                         Expanded Dos Attributes: -
                                             Unix User Id: 0
                                             Unix Group Id: 0
                                             Unix Mode Bits: 777
                                         Unix Mode Bits in Text: rwxrwxrwx
                                             ACLs: NTFS Security Descriptor
                                                 Control:0x8514
                                                 Owner:BUILTIN\Administrators
                                                 Group:BUILTIN\Administrators
                                                 DACL - ACES
                                                 ALLOW-Everyone-0x1f01ff-OI|CI (Inherited)
                                         Vserver: vs1
                                         File Path: /1/1/abc
                                         Security Style: mixed
                                         Effective Style: ntfs
                                         DOS Attributes: 10
                                         DOS Attributes in Text: ----D---
                                         Expanded Dos Attributes: -
                                             Unix User Id: 0
                                             Unix Group Id: 0
                                             Unix Mode Bits: 777
                                         Unix Mode Bits in Text: rwxrwxrwx
                                             ACLs: NTFS Security Descriptor
                                                 Control:0x8404
                                                 Owner:BUILTIN\Administrators
                                                 Group:BUILTIN\Administrators
                                                 DACL - ACES
                                                 ALLOW-Everyone-0x1f01ff-OI|CI (Inherited)

```

The following command displays the information of a file named as "##" under the path /vol1/a of SVM vs1. The path is enclosed within double quotes ("").

```

cluster::> vserver security file-directory show -vserver vs1 -path
"/vol1/a/*"

          Vserver: vs1
          File Path: "/vol1/a/*"
          Security Style: mixed
          Effective Style: unix
          DOS Attributes: 10
          DOS Attributes in Text: ----D---

= Manage NTFS file security, NTFS audit policies, and Storage-Level Access Guard on SVMs using the CLI

= Manage NTFS file security, NTFS audit policies, and Storage-Level Access Guard on SVMs using the CLI overview

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..../media/

You can manage NTFS file security, NTFS audit policies, and Storage-Level Access Guard on storage virtual machines (SVMs) by using the CLI.

You can manage NTFS file security and audit policies from SMB clients or by using the CLI. However, using the CLI to configure file security and audit policies removes the need to use a remote client to manage file security. Using the CLI can significantly reduce the time it takes to apply security on many files and folders using a single command.

You can configure Storage-Level Access Guard, which is another layer of security applied by ONTAP to SVM volumes. Storage-Level Access Guard applies to accesses from all NAS protocols to the storage object to which Storage-Level Access Guard is applied.

Storage-Level Access Guard can be configured and managed only from the ONTAP CLI. You cannot manage Storage-Level Access Guard settings from SMB clients. Moreover, if you view the security settings on a file or directory from an NFS or SMB client, you will not see the Storage-Level Access Guard security. Storage-Level Access Guard security cannot be revoked from a client, even by a system (Windows or UNIX) administrator. Therefore, Storage-Level Access Guard provides an extra layer of

security for data access that is independently set and managed by the storage administrator.

Even though only NTFS access permissions are supported for Storage-Level Access Guard, ONTAP can perform security checks for access over NFS to data on volumes where Storage-Level Access Guard is applied if the UNIX user maps to a Windows user on the SVM that owns the volume.

== NTFS security-style volumes

All files and folders contained within NTFS security-style volumes and qtrees have NTFS effective security. You can use the `vserver security file-directory` command family to implement the following types of security on NTFS security-style volumes:

- File permissions and audit policies to files and folders contained in the volume
- Storage-Level Access Guard security on volumes

== Mixed security-style volumes

Mixed security-style volumes and qtrees can contain some files and folders that have UNIX effective security and use UNIX file permissions, either mode bits or NFSv4.x ACLs and NFSv4.x audit policies, and some files and folders that have NTFS effective security and use NTFS file permissions and audit policies. You can use the `vserver security file-directory` command family to apply the following types of security to mixed security-style data:

- File permissions and audit policies to files and folders with NTFS effective security-style in the mixed volume or qtree
- Storage-Level Access Guard to volumes with either NTFS and UNIX effective security-style

== UNIX security-style volumes

UNIX security-style volumes and qtrees contain files and folders that have UNIX effective security (either mode bits or NFSv4.x ACLs). You must keep the following in mind if you want to use the `vserver security file-directory` command family to implement security on UNIX security-style volumes:

- The `vserver security file-directory` command family cannot be used to manage UNIX file security and audit policies on UNIX security-style volumes and qtrees.
- You can use the `vserver security file-directory` command family to configure Storage-Level Access Guard on UNIX security-style volumes, provided the SVM with the target volume contains a CIFS server.

= Use cases for using the CLI to set file and folder security

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Because you can apply and manage file and folder security locally without involvement from a remote client, you can significantly reduce the time it takes to set bulk security on a large number of files or folders.

You can benefit from using the CLI to set file and folder security in the following use cases:

- Storage of files in large enterprise environments, such as file storage in home directories
- Migration of data
- Change of Windows domain
- Standardization of file security and audit policies across NTFS file systems

= Limits when using the CLI to set file and folder security

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

You need to be aware of certain limits when using the CLI to set file and folder security.

- The vserver security file-directory command family does not support setting NFSv4 ACLs.

You can only apply NTFS security descriptors to NTFS files and folders.

= How security descriptors are used to apply file and folder security

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

Security descriptors contain the access control lists that determine what actions a user can perform on files and folders, and what is audited when a user accesses files and folders.

- **Permissions**

Permissions are allowed or denied by an object's owner and determine what actions an object (users, groups, or computer objects) can perform on specified files or folders.

- **Security descriptors**

Security descriptors are data structures that contain security information that define permissions associated with a file or folder.

- **Access control lists (ACLs)**

Access control lists are the lists contained within a security descriptor that contain information on what actions users, groups, or computer objects can perform on the file or folder to which the security descriptor is applied. The security descriptor can contain the following two types of ACLs:

- Discretionary access control lists (DACLs)
- System access control lists (SACLs)

- **Discretionary access control lists (DACLs)**

DACLs contain the list of SIDS for the users, groups, and computer objects who are allowed or denied access to perform actions on files or folders. DACLs contain zero or more access control entries (ACEs).

- **System access control lists (SACLs)**

SACLs contain the list of SIDS for the users, groups, and computer objects for which successful or failed auditing events are logged. SACLs contain zero or more access control entries (ACEs).

- **Access Control Entries (ACEs)**

ACEs are individual entries in either DACLs or SACLs:

- A DACL access control entry specifies the access rights that are allowed or denied for particular users, groups, or computer objects.
- A SACL access control entry specifies the success or failure events to log when auditing specified actions performed by particular users, groups, or computer objects.

- **Permission inheritance**

Permission inheritance describes how permissions defined in security descriptors are propagated to an object from a parent object. Only inheritable permissions are inherited by child objects. When setting permissions on the parent object, you can decide whether folders, sub-folders, and files can inherit them with “Apply to this-folder, sub-folders, and files”.

[Configuring and applying audit policies to NTFS files and folders using the CLI](#)

= Guidelines for applying file-directory policies that use local users or groups on the SVM disaster recovery destination

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

There are certain guidelines that you must keep in mind before applying file-directory policies on the storage virtual machine (SVM) disaster recovery destination in an ID discard configuration if your file-directory policy configuration uses local users or groups in either the security descriptor or the DACL or SACL entries.

You can configure a disaster recovery configuration for an SVM where the source SVM on the source cluster replicates the data and configuration from the source SVM to a destination SVM on a destination cluster.

You can set up one of two types of SVM disaster recovery:

- Identity preserved

With this configuration, the identity of the SVM and the CIFS server is preserved.

- Identity discarded

With this configuration, the identity of the SVM and the CIFS server is not preserved. In this scenario, the name of the SVM and the CIFS server on the destination SVM is different from the SVM and the CIFS server name on the source SVM.

== Guidelines for identity discarded configurations

In an identity discarded configuration, for an SVM source that contains local user, group, and privilege configurations, the name of the local domain (local CIFS server name) must be changed to match the CIFS server name on the SVM destination. For example, if the source SVM name is “vs1” and CIFS server name is “CIFS1”, and the destination SVM name is “vs1_dst” and the CIFS server name is “CIFS1_DST”, then the local domain name for a local user named “CIFS1\user1” is automatically changed to “CIFS1_DST\user1” on the destination SVM:

```
cluster1::> vserver cifs users-and-groups local-user show -vserver
vs1_dst

Vserver      User Name          Full Name        Description
-----
vs1          CIFS1\Administrator
administrator account
vs1          CIFS1\user1           -              -
cluster1dst::> vserver cifs users-and-groups local-user show -vserver
vs1_dst

Vserver      User Name          Full Name        Description
-----
vs1_dst      CIFS1_DST\Administrator
administrator account
vs1_dst      CIFS1_DST\user1       -              -
```

Even though local user and group names are automatically changed in the local user and group databases, local users or group names are not automatically changed in file-directory policy configurations (policies configured on the CLI using the `vserver security file-directory` command family).

For example, for “vs1”, if you have configured a DACL entry where the `-account` parameter is set to “CIFS1\user1”, the setting is not automatically changed on the destination SVM to reflect the destination’s CIFS server name.

```

cluster1::> vserver security file-directory ntfs dacl show -vserver vs1

Vserver: vs1
    NTFS Security Descriptor Name: sd1

    Account Name      Access      Access          Apply To
                  Type        Rights
    -----
    CIFS1\user1       allow       full-control   this-folder

cluster1::> vserver security file-directory ntfs dacl show -vserver
vs1_dst

Vserver: vs1_dst
    NTFS Security Descriptor Name: sd1

    Account Name      Access      Access          Apply To
                  Type        Rights
    -----
    **CIFS1**\user1     allow       full-control   this-folder

```

You must use the `vserver security file-directory modify` commands to manually change the CIFS server name to the destination CIFS server name.

== File-directory policy configuration components that contain account parameters

There are three file-directory policy configuration components that can use parameter settings that can contain local users or groups:

- Security descriptor

You can optionally specify the owner of the security descriptor and the primary group of the owner of the security descriptor. If the security descriptor uses a local user or group for the owner and primary group entries, you must modify the security descriptor to use the destination SVM in the account name. You can use the `vserver security file-directory ntfs modify` command to make any necessary changes to the account names.

- DACL entries

Each DACL entry must be associated with an account. You must modify any DACLs that use local user or group accounts to use the destination SVM name. Because you cannot modify the account name for existing DACL entries, you must remove any DACL entries with local users or groups from the security descriptors, create new DACL entries with the corrected destination account names, and associate these new DACL entries with the appropriate security descriptors.

- SACL entries

Each SACL entry must be associated with an account. You must modify any SACLs that use local user or group accounts to use the destination SVM name. Because you cannot modify the account name for existing SACL entries, you must remove any SACL entries with local users or groups from

the security descriptors, create new SACL entries with the corrected destination account names, and associate these new SACL entries with the appropriate security descriptors.

You must make any necessary changes to local users or groups used in the file-directory policy configuration before applying the policy; otherwise, the apply job fails.

= Configure and apply file security on NTFS files and folders using the CLI

= Create an NTFS security descriptor

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

Creating an NTFS security descriptor (file security policy) is the first step in configuring and applying NTFS access control lists (ACLs) to files and folders residing within storage virtual machines (SVMs). You can associate the security descriptor to the file or folder path in a policy task.

About this task

You can create NTFS security descriptors for files and folders residing within NTFS security-style volumes, or for files and folders residing on mixed security-style volumes.

By default, when a security descriptor is created, four discretionary access control list (DACL) access control entries (ACEs) are added to that security descriptor. The four default ACEs are as follows:

Object	Access type	Access rights	Where to apply the permissions
BUILTIN\Administrators	Allow	Full Control	this-folder, sub-folders, files
BUILTIN\Users	Allow	Full Control	this-folder, sub-folders, files
CREATOR OWNER	Allow	Full Control	this-folder, sub-folders, files
NT AUTHORITY\SYSTEM	Allow	Full Control	this-folder, sub-folders, files

You can customize the security descriptor configuration by using the following optional parameters:

- Owner of the security descriptor
- Primary group of the owner
- Raw control flags

The value for any optional parameter is ignored for Storage-Level Access Guard. See the man pages for more information.

= Add NTFS DACL access control entries to the NTFS security descriptor

```
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

Adding DACL (discretionary access control list) access control entries (ACEs) to the NTFS security descriptor is the second step in configuring and applying NTFS ACLs to a file or folder. Each entry identifies which object is allowed or denied access, and defines what the object can or cannot do to the files or folders defined in the ACE.

About this task

You can add one or more ACEs to the security descriptor's DACL.

If the security descriptor contains a DACL that has existing ACEs, the command adds the new ACE to the DACL. If the security descriptor does not contain a DACL, the command creates the DACL and adds the new ACE to it.

You can optionally customize DACL entries by specifying what rights you want to allow or deny for the account specified in the `-account` parameter. There are three mutually exclusive methods for specifying rights:

- Rights
- Advanced rights
- Raw rights (advanced-privilege)

If you do not specify rights for the DACL entry, the default is to set the rights to Full Control.

You can optionally customize DACL entries by specifying how to apply inheritance.

The value for any optional parameter is ignored for Storage-Level Access Guard. See the man pages for more information.

Steps

1. Add a DACL entry to a security descriptor:
`vserver security file-directory ntfs dacl add -vserver vserver_name -ntfs-sd SD_name -access-type {allow|deny} -account name_or_SID optional_parameters`

`vserver security file-directory ntfs dacl add -ntfs-sd sd1 -access-type deny -account domain\joe -rights full-control -apply-to this-folder -vserver vs1`
2. Verify that the DACL entry is correct:
`vserver security file-directory ntfs dacl show -vserver vserver_name -ntfs-sd SD_name -access-type {allow|deny} -account name_or_SID`

`vserver security file-directory ntfs dacl show -vserver vs1 -ntfs-sd sd1 -access-type deny -account domain\joe`

```

        Vserver: vs1
        Security Descriptor Name: sd1
            Allow or Deny: deny
            Account Name or SID: DOMAIN\joe
            Access Rights: full-control
            Advanced Access Rights: -
                Apply To: this-folder
                Access Rights: full-control

```

= Create security policies
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

Creating a file security policy for SVMs is the third step in configuring and applying ACLs to a file or folder. A policy acts as a container for various tasks, where each task is a single entry that can be applied to files or folders. You can add tasks to the security policy later.

About this task

The tasks that you add to a security policy contain associations between the NTFS security descriptor and the file or folder paths. Therefore, you should associate the security policy with each SVM (containing NTFS security-style volumes or mixed security-style volumes).

Steps

1. Create a security policy: vserver security file-directory policy create -vserver vserver_name -policy-name policy_name

```
vserver security file-directory policy create -policy-name policy1 -vserver
vs1
```
2. Verify the security policy: vserver security file-directory policy show

vserver security file-directory policy show	
Vserver	Policy Name
-----	-----
vs1	policy1

= Add a task to the security policy
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

Creating and adding a policy task to a security policy is the fourth step in configuring and applying ACLs to files or folders in SVMs. When you create the policy task, you associate the task with a security policy. You can add one or more task entries to a

security policy.

About this task

The security policy is a container for a task. A task refers to a single operation that can be done by a security policy to files or folders with NTFS or mixed security (or to a volume object if configuring Storage-Level Access Guard).

There are two types of tasks:

- File and directory tasks

Used to specify tasks that apply security descriptors to specified files and folders. ACLs applied through file and directory tasks can be managed with SMB clients or the ONTAP CLI.

- Storage-Level Access Guard tasks

Used to specify tasks that apply Storage-Level Access Guard security descriptors to a specified volume. ACLs applied through Storage-Level Access Guard tasks can be managed only through the ONTAP CLI.

A task contains definitions for the security configuration of a file (or folder) or set of files (or folders). Every task in a policy is uniquely identified by the path. There can be only one task per path within a single policy. A policy cannot have duplicate task entries.

Guidelines for adding a task to a policy:

- There can be a maximum of 10,000 tasks entries per policy.
- A policy can contain one or more tasks.

Even though a policy can contain more than one task, you cannot configure a policy to contain both file-directory and Storage-Level Access Guard tasks. A policy must contain either all Storage-Level Access Guard tasks or all file-directory tasks.

- Storage-Level Access Guard is used to restrict permissions.

It will never give extra access permissions.

When adding tasks to security policies, you must specify the following four required parameters:

- SVM name
- Policy name
- Path
- Security descriptor to associate with the path

You can customize the security descriptor configuration by using the following optional parameters:

- Security type
- Propagation mode
- Index position
- Access control type

The value for any optional parameter is ignored for Storage-Level Access Guard. See the man pages for more information.

Steps

1. Add a task with an associated security descriptor to the security policy: `vserver security file-directory policy task add -vserver vserver_name -policy-name policy_name -path path -ntfs-sd SD_nameoptional_parameters`

`file-directory` is the default value for the `-access-control` parameter. Specifying the access control type when configuring file and directory access tasks is optional.

```
vserver security file-directory policy task add -vserver vs1 -policy-name policy1 -path /home/dir1 -security-type ntfs -ntfs-mode propagate -ntfs-sd sd2 -index-num 1 -access-control file-directory
```

2. Verify the policy task configuration: `vserver security file-directory policy task show -vserver vserver_name -policy-name policy_name -path path`

```
vserver security file-directory policy task show
```

Vserver: vs1		Policy: policy1			
Index	File/Folder Security Descriptor Name	Access Path	Control	Security Type	NTFS Mode
-----	-----	-----	-----	-----	-----
-----	-----	-----	-----	-----	-----
1	/home/dir1	file-directory	ntfs	propagate	sd2

= Apply security policies

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

Applying a file security policy to SVMs is the last step in creating and applying NTFS ACLs to files or folders.

About this task

You can apply security settings defined in the security policy to NTFS files and folders residing within FlexVol volumes (NTFS or mixed security style).

Step

1. Apply a security policy: `vserver security file-directory apply -vserver vserver_name -policy-name policy_name`

```
vserver security file-directory apply -vserver vs1 -policy-name policy1
```

The policy apply job is scheduled and the Job ID is returned.

```
[Job 53322] Job is queued: Fsecurity Apply. Use the "Job show 53322 -id 53322" command to view the status of the operation
```

= Monitor the security policy job

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

When applying the security policy to storage virtual machines (SVMs), you can monitor the progress of the task by monitoring the security policy job. This is helpful if you want to ascertain that the application of the security policy succeeded. This is also helpful if you have a long-running job where you are applying bulk security to a large number of files and folders.

About this task

To display detailed information about a security policy job, you should use the `-instance` parameter.

Step

1. Monitor the security policy job: `vserver security file-directory job show -vserver vserver_name`

```
vserver security file-directory job show -vserver vs1
```

Job ID	Name	Vserver	Node	State
53322	Fsecurity Apply	vs1	node1	Success
Description: File Directory Security Apply Job				

= Verify the applied file security

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can verify the file security settings to confirm that the files or folders on the storage virtual machine (SVM) to which you applied the security policy have the desired settings.

About this task

You must supply the name of the SVM that contains the data and the path to the file and folders on which you want to verify security settings. You can use the optional `-expand-mask` parameter to display detailed information about the security settings.

Step

1. Display file and folder security settings: `vserver security file-directory show -vserver`

```
vserver_name -path path [-expand-mask true]

vserver security file-directory show -vserver vs1 -path /data/engineering
-expand-mask true
```

```
Vserver: vs1
      File Path: /data/engineering
      File Inode Number: 5544
      Security Style: ntfs

= Configure and apply audit policies to NTFS files and folders using the CLI overview

Icons font

:relative path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/.media/

There are several steps you must perform to apply audit policies to NTFS files and folders when using the ONTAP CLI. First, you create an NTFS security descriptor and add SACLs to the security descriptor. Next you create a security policy and add policy tasks. You then apply the security policy to a storage virtual machine (SVM).

About this task

After applying the security policy, you can monitor the security policy job and then verify the settings for the applied audit policy.

When an audit policy and associated SACLs are applied, any existing DACLs are overwritten. You should review existing security policies before creating and applying new ones.

Related information

[Securing file access by using Storage-Level Access Guard](#)

[Limits when using the CLI to set file and folder security](#)

[Configure and apply file security on NTFS files and folders using the CLI](#)

= Create an NTFS security descriptor

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Creating an NTFS security descriptor audit policy is the first step in configuring and applying NTFS access control lists (ACLs) to files and folders residing within SVMs. You will associate the security descriptor to the file or folder path in a policy task.

About this task

You can create NTFS security descriptors for files and folders residing within NTFS security-style volumes, or for files and folders residing on mixed security-style volumes.

By default, when a security descriptor is created, four discretionary access control list (DACL) access control entries (ACEs) are added to that security descriptor. The four default ACEs are as follows:

Object	Access type	Access rights	Where to apply the permissions
BUILTIN\Administrators	Allow	Full Control	this-folder, sub-folders, files
BUILTIN\Users	Allow	Full Control	this-folder, sub-folders, files
CREATOR OWNER	Allow	Full Control	this-folder, sub-folders, files
NT AUTHORITY\SYSTEM	Allow	Full Control	this-folder, sub-folders, files

You can customize the security descriptor configuration by using the following optional parameters:

- Owner of the security descriptor
- Primary group of the owner
- Raw control flags

The value for any optional parameter is ignored for Storage-Level Access Guard. See the man pages for more information.

Steps

1. If you want to use the advanced parameters, set the privilege level to advanced: `set -privilege advanced`
2. Create a security descriptor: `vserver security file-directory ntfs create -vserver vserver_name -ntfs-sd SD_nameoptional_parameters`
`vserver security file-directory ntfs create -ntfs-sd sd1 -vserver vs1 -owner DOMAIN\joe`
3. Verify that the security descriptor configuration is correct: `vserver security file-directory ntfs show -vserver vserver_name -ntfs-sd SD_name`

```
vserver security file-directory ntfs show -vserver vs1 -ntfs-sd sd1
```

```
Vserver: vs1
Security Descriptor Name: sd1
Owner of the Security Descriptor: DOMAIN\joe
```

4. If you are in the advanced privilege level, return to the admin privilege level: `set -privilege admin`

= Add NTFS SACL access control entries to the NTFS security descriptor

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Adding SACL (system access control list) access control entries (ACEs) to the NTFS security descriptor is the second step in creating NTFS audit policies for files or folders in SVMs. Each entry identifies the user or group that you want to audit. The SACL entry defines whether you want to audit successful or failed access attempts.

About this task

You can add one or more ACEs to the security descriptor's SACL.

If the security descriptor contains a SACL that has existing ACEs, the command adds the new ACE to the SACL. If the security descriptor does not contain a SACL, the command creates the SACL and adds the new ACE to it.

You can configure SACL entries by specifying what rights you want to audit for success or failure events for the account specified in the –account parameter. There are three mutually exclusive methods for

specifying rights:

- Rights
- Advanced rights
- Raw rights (advanced-privilege)

If you do not specify rights for the SACL entry, the default setting is Full Control.

You can optionally customize SACL entries by specifying how to apply inheritance with the `apply-to` parameter. If you do not specify this parameter, the default is to apply this SACL entry to this folder, subfolders, and files.

Steps

1. Add a SACL entry to a security descriptor: `vserver security file-directory ntfs acl add -vserver vserver_name -ntfs-sd SD_name -access-type {failure|success} -account name_or_SID optional_parameters`

```
vserver security file-directory ntfs acl add -ntfs-sd sd1 -access-type failure -account domain\joe -rights full-control -apply-to this-folder -vserver vs1
```

2. Verify that the SACL entry is correct: `vserver security file-directory ntfs acl show -vserver vserver_name -ntfs-sd SD_name -access-type {failure|success} -account name_or_SID`

```
vserver security file-directory ntfs acl show -vserver vs1 -ntfs-sd sd1 -access-type deny -account domain\joe
```

```
Vserver: vs1
Security Descriptor Name: sd1
Access type for Specified Access Rights: failure
Account Name or SID: DOMAIN\joe
Access Rights: full-control
Advanced Access Rights: -
Apply To: this-folder
Access Rights: full-control
```

= Create security policies

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

Creating an audit policy for storage virtual machines (SVMs) is the third step in configuring and applying ACLs to a file or folder. A policy acts as a container for various tasks, where each task is a single entry that can be applied to files or folders. You can add tasks to the security policy later.

About this task

The tasks that you add to a security policy contain associations between the NTFS security descriptor and the file or folder paths. Therefore, you should associate the security policy with each storage virtual machine (SVM) (containing NTFS security-style volumes or mixed security-style volumes).

Steps

1. Create a security policy: `vserver security file-directory policy create -vserver vserver_name -policy-name policy_name`

```
vserver security file-directory policy create -policy-name policy1 -vserver vs1
```

2. Verify the security policy: `vserver security file-directory policy show`

```
vserver security file-directory policy show
      Vserver          Policy Name
-----
      vs1            policy1
```

= Add a task to the security policy

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Creating and adding a policy task to a security policy is the fourth step in configuring and applying ACLs to files or folders in SVMs. When you create the policy task, you associate the task with a security policy. You can add one or more task entries to a security policy.

About this task

The security policy is a container for a task. A task refers to a single operation that can be done by a security policy to files or folders with NTFS or mixed security (or to a volume object if configuring Storage-Level Access Guard).

There are two types of tasks:

- File and directory tasks

Used to specify tasks that apply security descriptors to specified files and folders. ACLs applied through file and directory tasks can be managed with SMB clients or the ONTAP CLI.

- Storage-Level Access Guard tasks

Used to specify tasks that apply Storage-Level Access Guard security descriptors to a specified volume. ACLs applied through Storage-Level Access Guard tasks can be managed only through the ONTAP CLI.

A task contains definitions for the security configuration of a file (or folder) or set of files (or folders). Every task in a policy is uniquely identified by the path. There can be only one task per path within a single policy. A policy cannot have duplicate task entries.

Guidelines for adding a task to a policy:

- There can be a maximum of 10,000 tasks entries per policy.
- A policy can contain one or more tasks.

Even though a policy can contain more than one task, you cannot configure a policy to contain both file-directory and Storage-Level Access Guard tasks. A policy must contain either all Storage-Level Access Guard tasks or all file-directory tasks.

- Storage-Level Access Guard is used to restrict permissions.

It will never give extra access permissions.

You can customize the security descriptor configuration by using the following optional parameters:

- Security type
- Propagation mode
- Index position
- Access control type

The value for any optional parameter is ignored for Storage-Level Access Guard. See the man pages for more information.

Steps

1. Add a task with an associated security descriptor to the security policy: `vserver security file-directory policy task add -vserver vserver_name -policy-name policy_name -path path -ntfs-sd SD_nameoptional_parameters`

`file-directory` is the default value for the `-access-control` parameter. Specifying the access control type when configuring file and directory access tasks is optional.

```
vserver security file-directory policy task add -vserver vs1 -policy-name policy1 -path /home/dirl -security-type ntfs -ntfs-mode propagate -ntfs-sd sd2 -index-num 1 -access-control file-directory
```

2. Verify the policy task configuration: `vserver security file-directory policy task show -vserver vserver_name -policy-name policy_name -path path`

```
vserver security file-directory policy task show
```

Vserver: vsl					
Policy: policy1					
Index	File/Folder Descriptor	Access Control	Security Type	NTFS Mode	NTFS Mode
Security Name	Path	Descriptor	Type	Mode	Mode
-----	-----	-----	-----	-----	-----
-----	-----	-----	-----	-----	-----
1	/home/dir1	file-directory	ntfs	propagate	sd2

= Apply security policies

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Applying an audit policy to SVMsis the last step in creating and applying NTFS ACLs to files or folders.

About this task

You can apply security settings defined in the security policy to NTFS files and folders residing within FlexVol volumes (NTFS or mixed security style).

Step

1. Apply a security policy: `vserver security file-directory apply -vserver vserver_name -policy-name policy_name`

`vserver security file-directory apply -vserver vsl -policy-name policy1`

The policy apply job is scheduled and the Job ID is returned.

[Job 53322] Job is queued: Fsecurity Apply. Use the "Job show 53322 -id 53322" command to view the status of the operation

= Monitor the security policy job

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

When applying the security policy to storage virtual machines (SVMs), you can monitor the progress of the task by monitoring the security policy job. This is helpful if you want to ascertain that the application of the security policy succeeded. This is also helpful if you have a long-running job where you are applying bulk security to a large number of files and folders.

About this task

To display detailed information about a security policy job, you should use the `-instance` parameter.

Step

1. Monitor the security policy job:
`vserver security file-directory job show -vserver vserver_name`

`vserver security file-directory job show -vserver vs1`

Job ID	Name	Vserver	Node	State
53322	Fsecurity Apply	vs1	node1	Success
Description: File Directory Security Apply Job				

= Verify the applied audit policy

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can verify the audit policy to confirm that the files or folders on the storage virtual machine (SVM) to which you applied the security policy have the desired audit security settings.

About this task

You use the `vserver security file-directory show` command to display audit policy information. You must supply the name of the SVM that contains the data and the path to the data whose file or folder audit policy information you want to display.

Step

1. Display audit policy settings:
`vserver security file-directory show -vserver vserver_name -path path`

Example

The following command displays the audit policy information applied to the path “/corp” in SVM vs1. The path has both a SUCCESS and a SUCCESS/FAIL SACL entry applied to it:

```

cluster::> vserver security file-directory show -vserver vs1 -path
/corp

          Vserver: vs1
          File Path: /corp
          Security Style: ntfs
          Effective Style: ntfs
          DOS Attributes: 10
          DOS Attributes in Text: ----D---
Expanded Dos Attributes: -
          Unix User Id: 0
          Unix Group Id: 0

          Unix Mode Bits in Text: rwxrwxrwx
          ACLs: NTFS Security Descriptor
          Control:0x8014
          Owner:DOMAIN\Administrator
          Group:BUILTIN\Administrators
          SACL - ACES
          ALL-DOMAIN\Administrator-0x100081-
OI|CI|SA|FA
          SUCCESSFUL-DOMAIN\user1-0x100116-OI|CI|SA
          DACL - ACES
          ALLOW-BUILTIN\Administrators-0x1f01ff-OI|CI
          ALLOW-BUILTIN\Users-0x1f01ff-OI|CI
          ALLOW-CREATOR OWNER-0x1f01ff-OI|CI
          ALLOW-NT AUTHORITY\SYSTEM-0x1f01ff-OI|CI

```

= Considerations when managing security policy jobs

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If a security policy job exists, under certain circumstances, you cannot modify that security policy or the tasks assigned to that policy. You should understand under what conditions you can or cannot modify security policies so that any attempts that you make to modify the policy are successful. Modifications to the policy include adding, removing, or modifying tasks assigned to the policy and deleting or modifying the policy.

You cannot modify a security policy or a task assigned to that policy if a job exists for that policy and that job is in the following states:

- The job is running or in progress.
- The job is paused.

- The job is resumed and is in the running state.
- If the job is waiting to failover to another node.

Under the following circumstances, if a job exists for a security policy, you can successfully modify that security policy or a task assigned to that policy:

- The policy job is stopped.
- The policy job has successfully finished.

= Commands for managing NTFS security descriptors

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

There are specific ONTAP commands for managing security descriptors. You can create, modify, delete, and display information about security descriptors.

If you want to...	Use this command...
Create NTFS security descriptors	vserver security file-directory ntfs create
Modify existing NTFS security descriptors	vserver security file-directory ntfs modify
Display information about existing NTFS security descriptors	vserver security file-directory ntfs show
Delete NTFS security descriptors	vserver security file-directory ntfs delete

See the man pages for the `vserver security file-directory ntfs` commands for more information.

= Commands for managing NTFS DACL access control entries

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

There are specific ONTAP commands for managing DACL access control entries (ACEs). You can add ACEs to NTFS DACLs at any time. You can also manage existing NTFS DACLs by modifying, deleting, and displaying information about ACEs in DACLs.

If you want to...	Use this command...
Create ACEs and add them to NTFS DACLs	vserver security file-directory ntfs dacl add

If you want to...	Use this command...
Modify existing ACEs in NTFS DACLs	vserver security file-directory ntfs dacl modify
Display information about existing ACEs in NTFS DACLs	vserver security file-directory ntfs dacl show
Remove existing ACEs from NTFS DACLs	vserver security file-directory ntfs dacl remove

See the man pages for the `vserver security file-directory ntfs dacl` commands for more information.

= Commands for managing NTFS SACL access control entries

:icons: font

Resume security policy jobs	vserver security file-directory job resume -vserver vserver_name -id integer
Display information about security policy jobs	vserver security file-directory job show -vserver vserver_name You can determine the job ID of a job using this command.
Stop security policy jobs	vserver security file-directory job stop -vserver vserver_name -id integer

See the man pages for the `vserver security file-directory job` commands for more information.

= Configure the metadata cache for SMB shares

= How SMB metadata caching works

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Metadata caching enables file attribute caching on SMB 1.0 clients to provide faster access to file and folder attributes. You can enable or disable attribute caching on a per-share basis. You can also configure the time-to-live for cached entries if metadata caching is enabled. Configuring metadata caching is not necessary if clients are connecting to shares over SMB 2.x or SMB 3.0.

When enabled, the SMB metadata cache stores path and file attribute data for a limited amount of time. This can improve SMB performance for SMB 1.0 clients with common workloads.

For certain tasks, SMB creates a significant amount of traffic that can include multiple identical queries for path and file metadata. You can reduce the number of redundant queries and improve performance for SMB 1.0 clients by using SMB metadata caching to fetch information from the cache instead.

While unlikely, it is possible that the metadata cache might serve stale information to SMB 1.0 clients. If your environment cannot afford this risk, you should not enable this feature.

= Enable the SMB metadata cache

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can improve SMB performance for SMB 1.0 clients by enabling the SMB

metadata cache. By default, SMB metadata caching is disabled.

Step

1. Perform the desired action:

If you want to...	Enter the command...
Enable SMB metadata caching when you create a share	<code>vserver cifs share create -vserver vserver_name -share-name share_name -path path -share-properties attributecache</code>
Enable SMB metadata caching on an existing share	<code>vserver cifs share properties add -vserver vserver_name -share-name share_name -share-properties attributecache</code>

Related information

[Configuring the lifetime of SMB metadata cache entries](#)

[Adding or removing share properties on an existing SMB share](#)

= Configure the lifetime of SMB metadata cache entries

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can configure the lifetime of SMB metadata cache entries to optimize the SMB metadata cache performance in your environment. The default is 10 seconds.

Before you begin

You must have enabled the SMB metadata cache feature. If SMB metadata caching is not enabled, the SMB cache TTL setting is not used.

Step

1. Perform the desired action:

If you want to configure the lifetime of SMB metadata cache entries when you...	Enter the command...
Create a share	<code>vserver cifs share -create -vserver vserver_name -share-name share_name -path path -attribute-cache-ttl [integerh] [integerm] [integers]</code>
Modify an existing share	<code>vserver cifs share -modify -vserver vserver_name -share-name share_name -attribute-cache-ttl [integerh] [integerm] [integers]</code>

You can specify additional share configuration options and properties when you create or modify shares. See the man pages for more information.

= Manage file locks

= About file locking between protocols

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

File locking is a method used by client applications to prevent a user from accessing a file previously opened by another user. How ONTAP locks files depends on the protocol of the client.

If the client is an NFS client, locks are advisory; if the client is an SMB client, locks are mandatory.

Because of differences between the NFS and SMB file locks, an NFS client might fail to access a file previously opened by an SMB application.

The following occurs when an NFS client attempts to access a file locked by an SMB application:

- In mixed or NTFS volumes, file manipulation operations such as `rm`, `rmdir`, and `mv` can cause the NFS application to fail.
- NFS read and write operations are denied by SMB deny-read and deny-write open modes, respectively.
- NFS write operations fail when the written range of the file is locked with an exclusive SMB bytelock.

In UNIX security-style volumes, NFS unlink and rename operations ignore SMB lock state and allow access to the file. All other NFS operations on UNIX security-style volumes honor SMB lock state.

= How ONTAP treats read-only bits

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

The read-only bit is set on a file-by-file basis to reflect whether a file is writable (disabled) or read-only (enabled).

SMB clients that use Windows can set a per-file read-only bit. NFS clients do not set a per-file read-only bit because NFS clients do not have any protocol operations that use a per-file read-only bit.

ONTAP can set a read-only bit on a file when an SMB client that uses Windows creates that file. ONTAP can also set a read-only bit when a file is shared between NFS clients and SMB clients. Some software, when used by NFS clients and SMB clients, requires the read-only bit to be enabled.

For ONTAP to keep the appropriate read and write permissions on a file shared between NFS clients and SMB clients, it treats the read-only bit according to the following rules:

- NFS treats any file with the read-only bit enabled as if it has no write permission bits enabled.
- If an NFS client disables all write permission bits and at least one of those bits had previously been enabled, ONTAP enables the read-only bit for that file.

- If an NFS client enables any write permission bit, ONTAP disables the read-only bit for that file.
- If the read-only bit for a file is enabled and an NFS client attempts to discover permissions for the file, the permission bits for the file are not sent to the NFS client; instead, ONTAP sends the permission bits to the NFS client with the write permission bits masked.
- If the read-only bit for a file is enabled and an SMB client disables the read-only bit, ONTAP enables the owner's write permission bit for the file.
- Files with the read-only bit enabled are writable only by root.

Changes to file permissions take effect immediately on SMB clients, but might not take effect immediately on NFS clients if the NFS client enables attribute caching.

= How ONTAP differs from Windows on handling locks on share path components

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

Unlike Windows, ONTAP does not lock each component of the path to an open file while the file is open. This behavior also affects SMB share paths.

Because ONTAP does not lock each component of the path, it is possible to rename a path component above the open file or share, which can cause problems for certain applications, or can cause the share path in the SMB configuration to be invalid. This can cause the share to be inaccessible.

To avoid issues caused by renaming path components, you can apply security settings that prevent users or applications from renaming critical directories.

= Display information about locks

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

You can display information about the current file locks, including what types of locks are held and what the lock state is, details about byte-range locks, sharelock modes, delegation locks, and opportunistic locks, and whether locks are opened with durable or persistent handles.

About this task

The client IP address cannot be displayed for locks established through NFSv4 or NFSv4.1.

By default, the command displays information about all locks. You can use command parameters to display information about locks for a specific storage virtual machine (SVM) or to filter the command's output by other criteria.

The `vserver locks show` command displays information about four types of locks:

- Byte-range locks, which lock only a portion of a file.
- Share locks, which lock open files.
- Opportunistic locks, which control client-side caching over SMB.
- Delegations, which control client-side caching over NFSv4.x.

By specifying optional parameters, you can determine important information about each lock type. See the man page for the command for more information.

Step

1. Display information about locks by using the `vserver locks show` command.

Examples

The following example displays summary information for an NFSv4 lock on a file with the path `/vol1/file1`. The sharelock access mode is `write-deny_none`, and the lock was granted with write delegation:

```
cluster1::> vserver locks show

Vserver: vs0
Volume   Object Path          LIF      Protocol  Lock Type
Client

-----
-----
vol1     /vol1/file1         lif1     nfsv4    share-level -
          Sharelock Mode: write-deny_none
                                delegation -
          Delegation Type: write
```

The following example displays detailed oplock and sharelock information about the SMB lock on a file with the path `/data2/data2_2/intro.pptx`. A durable handle is granted on the file with a share lock access mode of `write-deny_none` to a client with an IP address of 10.3.1.3. A lease oplock is granted with a batch oplock level:

```
cluster1::> vserver locks show -instance -path
/data2/data2_2/intro.pptx

          Vserver: vs1
          Volume: data2_2
          Logical Interface: lif2
          Object Path: /data2/data2_2/intro.pptx
          Lock UUID: 553cf484-7030-4998-88d3-1125adbba0b7
          Lock Protocol: cifs
          Lock Type: share-level
          Node Holding Lock State: node3
          Lock State: granted
          Bytelock Starting Offset: -

```

= Break locks

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

When file locks are preventing client access to files, you can display information about currently held locks, and then break specific locks. Examples of scenarios in which you might need to break locks include debugging applications.

About this task

The `vserver locks break` command is available only at the advanced privilege level and higher. The man page for the command contains detailed information.

Steps

1. To find the information you need to break a lock, use the `vserver locks show` command.

The man page for the command contains detailed information.

2. Set the privilege level to advanced: `set -privilege advanced`
3. Perform one of the following actions:

If you want to break a lock by specifying...	Enter the command...
The SVM name, volume name, LIF name, and file path	<code>vserver locks break -vserver vserver_name -volume volume_name -path path -lif lif</code>
The lock ID	<code>vserver locks break -lockid UUID</code>

4. Return to the admin privilege level: `set -privilege admin`

= Monitor SMB activity

= Display SMB session information

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can display information about established SMB sessions, including the SMB connection and session ID and the IP address of the workstation using the session. You can display information about the session's SMB protocol version and continuously available protection level, which helps you identify whether the session supports nondisruptive operations.

About this task

You can display information for all of the sessions on your SVM in summary form. However, in many cases, the amount of output that is returned is large. You can customize what information is displayed in the output by specifying optional parameters:

- You can use the optional `-fields` parameter to display output about the fields you choose.

You can enter `-fields ?` to determine what fields you can use.

- You can use the `-instance` parameter to display detailed information about established SMB sessions.
- You can use the `-fields` parameter or the `-instance` parameter either alone or in combination with other optional parameters.

Step

1. Perform one of the following actions:

If you want to display SMB session information...	Enter the following command...
For all sessions on the SVM in summary form	<code>vserver cifs session show -vserver vserver_name</code>
On a specified connection ID	<code>vserver cifs session show -vserver vserver_name -connection-id integer</code>
From a specified workstation IP address	<code>vserver cifs session show -vserver vserver_name -address workstation_IP_address</code>
On a specified LIF IP address	<code>vserver cifs session show -vserver vserver_name -lif-address LIF_IP_address</code>
On a specified node	<code>vserver cifs session show -vserver vserver_name -node {node_name local}</code>
From a specified Windows user	<code>vserver cifs session show -vserver vserver_name -windows-user domain_name\\user_name</code>
With a specified authentication mechanism	<code>vserver cifs session show -vserver vserver_name -auth-mechanism {NTLMv1 NTLMv2 Kerberos Anonymous}</code>
With a specified protocol version	<p><code>vserver cifs session show -vserver vserver_name -protocol-version {SMB1 SMB2 SMB2_1 SMB3 SMB3_1}</code></p> <div style="text-align: right; margin-top: 10px;">  Continuously available protection and SMB Multichannel are available only on SMB 3.0 and later sessions. To view their status on all qualifying sessions, you should specify this parameter with the value set to SMB3 or later. </div>

If you want to display SMB session information...	Enter the following command...
With a specified level of continuously available protection	<pre>vserver cifs session show -vserver vserver_name -continuously-available {No Yes Partial}</pre> <p> If the continuously available status is Partial, this means that the session contains at least one open continuously available file, but the session has some files that are not open with continuously available protection. You can use the vserver cifs sessions file show command to determine which files on the established session are not open with continuously available protection.</p>
With a specified SMB signing session status	<pre>vserver cifs session show -vserver vserver_name -is-session-signed {true false}</pre>

Examples

The following command displays session information for the sessions on SVM vs1 established from a workstation with IP address 10.1.1.1:

```
cluster1::> vserver cifs session show -address 10.1.1.1
Node:      node1
Vserver:   vs1
Connection Session
ID          ID      Workstation           Windows User      Open      Idle
-----  -----  -----
3151272279,
3151272280,
3151272281  1      10.1.1.1            DOMAIN\joe      2        23s
```

The following command displays detailed session information for sessions with continuously available protection on SVM vs1. The connection was made by using the domain account.

```
cluster1::> vserver cifs session show -instance -continuously-available
Yes

          Node: node1
          Vserver: vs1
          Session ID: 1
          Connection ID: 3151274158
Incoming Data LIF IP Address: 10.2.1.1
          Workstation IP address: 10.1.1.2
          Authentication Mechanism: Kerberos
          Windows User: DOMAIN\SERVER1$
          UNIX User: pcuser
          Open Shares: 1
          Open Files: 1
          Open Other: 0
          Connected Time: 10m 43s
          Idle Time: 1m 19s
          Protocol Version: SMB3
Continuously Available: Yes
          Is Session Signed: false
          User Authenticated as: domain-user
          NetBIOS Name: -
SMB Encryption Status: Unencrypted
```

The following command displays session information on a session using SMB 3.0 and SMB Multichannel on SVM vs1. In the example, the user connected to this share from an SMB 3.0 capable client by using the LIF IP address; therefore, the authentication mechanism defaulted to NTLMv2. The connection must be made by using Kerberos authentication to connect with continuously available protection.

```
cluster1::> vserver cifs session show -instance -protocol-version SMB3

        Node: node1
        Vserver: vs1
        Session ID: 1
        **Connection IDs: 3151272607,31512726078,3151272609
        Connection Count: 3**
Incoming Data LIF IP Address: 10.2.1.2
        Workstation IP address: 10.1.1.3
        Authentication Mechanism: NTLMv2
            Windows User: DOMAIN\administrator
            UNIX User: pcuser
        Open Shares: 1
            Open Files: 0
            Open Other: 0
        Connected Time: 6m 22s
            Idle Time: 5m 42s
        Protocol Version: SMB3
Continuously Available: No
        Is Session Signed: false
        User Authenticated as: domain-user
            NetBIOS Name: -
        SMB Encryption Status: Unencrypted
```

Related information

[Displaying information about open SMB files](#)

= Display information about open SMB files

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

You can display information about open SMB files, including the SMB connection and session ID, the hosting volume, the share name, and the share path. You can display information about a file's continuously available protection level, which is helpful in determining whether an open file is in a state that supports nondisruptive operations.

About this task

You can display information about open files on an established SMB session. The displayed information is useful when you need to determine SMB session information for particular files within an SMB session.

For example, if you have an SMB session where some of the open files are open with continuously available protection and some are not open with continuously available protection (the value for the -continuously-available field in `vserver cifs session show` command output is Partial), you can determine which files are not continuously available by using this command.

You can display information for all open files on established SMB sessions on storage virtual machines

(SVMs) in summary form by using the `vserver cifs session file show` command without any optional parameters.

However, in many cases, the amount of output returned is large. You can customize what information is displayed in the output by specifying optional parameters. This can be helpful when you want to view information for only a small subset of open files.

- You can use the optional `-fields` parameter to display output on the fields you choose.

You can use this parameter either alone or in combination with other optional parameters.

- You can use the `-instance` parameter to display detailed information about open SMB files.

You can use this parameter either alone or in combination with other optional parameters.

Step

1. Perform one of the following actions:

If you want to display open SMB files...	Enter the following command...
On the SVM in summary form	<code>vserver cifs session file show -vserver vserver_name</code>
On a specified node	<code>vserver cifs session file show -vserver vserver_name -node {node_name local}</code>
On a specified file ID	<code>vserver cifs session file show -vserver vserver_name -file-id integer</code>
On a specified SMB connection ID	<code>vserver cifs session file show -vserver vserver_name -connection-id integer</code>
On a specified SMB session ID	<code>vserver cifs session file show -vserver vserver_name -session-id integer</code>
On the specified hosting aggregate	<code>vserver cifs session file show -vserver vserver_name -hosting -aggregate aggregate_name</code>
On the specified volume	<code>vserver cifs session file show -vserver vserver_name -hosting -volume volume_name</code>

If you want to display open SMB files...	Enter the following command...
On the specified SMB share	<code>vserver cifs session file show -vserver vserver_name -share share_name</code>
On the specified SMB path	<code>vserver cifs session file show -vserver vserver_name -path path</code>
With the specified level of continuously available protection	<code>vserver cifs session file show -vserver vserver_name -continuously -available {No Yes}</code>
	<p> If the continuously available status is No, this means that these open files are not capable of nondisruptively recovering from takeover and giveback. They also cannot recover from general aggregate relocation between partners in a high-availability relationship.</p>
With the specified reconnected state	<code>vserver cifs session file show -vserver vserver_name -reconnected {No Yes}</code>
	<p> If the reconnected state is No, the open file is not reconnected after a disconnection event. This can mean that the file was never disconnected, or that the file was disconnected and is not successfully reconnected. If the reconnected state is Yes, this means that the open file is successfully reconnected after a disconnection event.</p>

There are additional optional parameters that you can use to refine the output results. See the man page for more information.

Examples

The following example displays information about open files on SVM vs1:

```

cluster1::> vserver cifs session file show -vserver vs1
Node:          node1
Vserver:       vs1
Connection:   3151274158
Session:      1
File    File      Open Hosting           Continuously
ID      Type      Mode Volume     Share
----- -----
41      Regular    r      data        data      Yes
Path: \mytest.rtf

```

The following example displays detailed information about open SMB files with file ID 82 on SVM vs1:

```

cluster1::> vserver cifs session file show -vserver vs1 -file-id 82
-instance

          Node: node1
          Vserver: vs1
          File ID: 82
          Connection ID: 104617
          Session ID: 1
          File Type: Regular
          Open Mode: rw
Aggregate Hosting File: aggr1
Volume Hosting File: data1
CIFS Share: data1
Path from CIFS Share: windows\win8\test\test.txt
Share Mode: rw
Range Locks: 1
Continuously Available: Yes
Reconnected: No

```

= Determine which statistics objects and counters are available

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Before you can obtain information about CIFS, SMB, auditing, and BranchCache hash statistics and monitor performance, you must know which objects and counters are available from which you can obtain data.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`

2. Perform one of the following actions:

If you want to determine...	Enter...
Which objects are available	<code>statistics catalog object show</code>
Specific objects that are available	<code>statistics catalog object show object object_name</code>
Which counters are available	<code>statistics catalog counter show object object_name</code>

See the man pages for more information about which objects and counters are available.

3. Return to the admin privilege level: `set -privilege admin`

Examples

The following command displays descriptions of selected statistic objects related to CIFS and SMB access in the cluster as seen at the advanced privilege level:

```

cluster1::> set -privilege advanced

Warning: These advanced commands are potentially dangerous; use them
only when directed to do so by support personnel.

[Displaying statistics](#)

```
= Display statistics
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin../media/
```

You can display various statistics, including statistics about CIFS and SMB, auditing, and BranchCache hashes, to monitor performance and diagnose issues.

Before you begin

You must have collected data samples by using the `statistics start` and `statistics stop` commands before you can display information about objects.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Perform one of the following actions:

If you want to display statistics for...	Enter...
All versions of SMB	<code>statistics show -object cifs</code>
SMB 1.0	<code>statistics show -object smb1</code>
SMB 2.x and SMB 3.0	<code>statistics show -object smb2</code>
CIFS subsystem of the node	<code>statistics show -object nblade_cifs</code>
Multiprotocol audit	<code>statistics show -object audit_ng</code>
BranchCache hash service	<code>statistics show -object hashd</code>
Dynamic DNS	<code>statistics show -object ddns_update</code>

See the man page for each command for more information.

3. Return to the admin privilege level: `set -privilege admin`

= Use offline files to allow caching of files for offline use

= Use offline files to allow caching of files for offline use overview

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

ONTAP supports the Microsoft Offline Files feature, or *client-side caching*, which allows files to be cached on the local host for offline use. Users can use the offline files functionality to continue working on files even when they are disconnected from the network.

You can specify whether Windows user documents and programs are automatically cached on a share or whether the files must be manually selected for caching. Manual caching is enabled by default for new shares. The files that are made available offline are synchronized to the Windows client's local disk. Synchronization occurs when network connectivity to a specific storage system share is restored.

Because offline files and folders retain the same access permissions as the version of the files and folders saved on the CIFS server, the user must have sufficient permissions on the files and folders saved on the CIFS server to perform actions on the offline files and folders.

When the user and someone else on the network make changes to the same file, the user can save the local version of the file to the network, keep the other version, or save both. If the user keeps both versions, a new file with the local user's changes is saved locally and the cached file is overwritten with changes from the version of the file saved on the CIFS server.

You can configure offline files on a share-by-share basis by using share configuration settings. You can choose one of the four offline folder configurations when you create or modify shares:

- No caching

Disables client-side caching for the share. Files and folders are not automatically cached locally on clients and users cannot choose to cache files or folders locally.

- Manual caching

Enables manual selection of files to be cached on the share. This is the default setting. By default, no files or folders are cached on the local client. Users can choose which files and folders they want to cache locally for offline use.

- Automatic document caching

Enables user documents to be automatically cached on the share. Only files and folders that are accessed are cached locally.

- Automatic program caching

Enables programs and user documents to be automatically cached on the share. Only files, folders, and programs that are accessed are cached locally. Additionally, this setting allows the client to run locally cached executables even when connected to the network.

For more information about configuring offline files on Windows servers and clients, consult the Microsoft

Before you can use the Microsoft Offline Files feature with your CIFS server, you need to know which versions of ONTAP and SMB and which Windows clients support the feature.

== ONTAP version requirements

ONTAP releases support offline files.

== SMB protocol version requirements

For storage virtual machine (SVM), ONTAP supports offline files on all versions of SMB.

== Windows client requirements

The Windows client must support the offline files.

For the latest information about which Windows clients supports the Offline Files feature, see the Interoperability Matrix.

[mysupport.netapp.com/matrix](#)

= Guidelines for deploying offline files

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

There are some important guidelines you need to understand when you deploy offline files on home directory shares that have the `showsnapshot` share property set on home directories.

If the `showsnapshot` share property is set on a home directory share that has offline files configured, Windows clients cache all of the Snapshot copies under the `~snapshot` folder in the user's home directory.

Windows clients cache all of the Snapshot copies under the home directory if one or more of the following is true:

- The user makes the home directory available offline from the client.

The contents of the ~snapshot folder in the home directory is included and made available offline.

- The user configures folder redirection to redirect a folder such as My Documents to the root of a home directory residing on the CIFS server share.

Some Windows clients might automatically make the redirected folder available offline. If the folder is redirected to the root of the home directory, the ~snapshot folder is included in the cached offline content.

Offline file deployments where the ~snapshot folder is included in offline files should be avoided. The Snapshot copies in the ~snapshot folder contain all data on the volume at the point at which ONTAP created the Snapshot copy. Therefore, creating an offline copy of the ~snapshot folder consumes significant local storage on the client, consumes network bandwidth during offline files synchronization, and increases the time it takes to synchronize offline files.

= Configure offline files support on SMB shares using the CLI

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can configure offline files support using the ONTAP CLI by specifying one of the four offline files setting when you create SMB shares or at any time by modifying existing SMB shares. Manual offline files support is the default setting.

About this task

When configuring offline files support, you can choose one of the following four offline files settings:

Setting	Description
none	Disallows Windows clients from caching any files on this share.
manual	Allows users on Windows clients to manually select files to be cached.
documents	Allows Windows clients to cache user documents that are used by the user for offline access.
programs	Allows Windows clients to cache programs that are used by the user for offline access. Clients can use the cached program files in offline mode even if the share is available.

You can choose only one offline file setting. If you modify an offline files setting on an existing SMB share, the new offline files setting replaces the original setting. Other existing SMB share configuration settings and share properties are not removed or replaced. They remain in effect until they are explicitly removed or changed.

Steps

1. Perform the appropriate action:

If you want to configure offline files on...	Enter the command...
A new SMB share	vserver cifs share create -vserver vserver_name -share-name share_name -path path -offline-files {none manual documents programs}
An existing SMB share	vserver cifs share modify -vserver vserver_name -share-name share_name -offline-files {none manual documents programs}

2. Verify that the SMB share configuration is correct: `vserver cifs share show -vserver vserver_name -share-name share_name -instance`

Example

The following command creates an SMB share named "data1" with offline files set to documents:

```
cluster1::> vserver cifs share create -vserver vs1 -share-name data1
-path /data1 -comment "Offline files" -offline-files documents

cluster1::> vserver cifs share show -vserver vs1 -share-name data1
-instance

          Vserver: vs1
          Share: data1
          CIFS Server NetBIOS Name: VS1
          Path: /data1
          Share Properties: oplocks
                           browsable
                           changenotify
          Symlink Properties: enable
          File Mode Creation Mask: -
          Directory Mode Creation Mask: -
          Share Comment: Offline files
          Share ACL: Everyone / Full Control
          File Attribute Cache Lifetime: -
          Volume Name: -
          Offline Files: documents
          Vscan File-Operations Profile: standard
          Maximum Tree Connections on Share: 4294967295
          UNIX Group for File Create: -
```

The following command modifies an existing SMB share named "data1" by changing the offline files

setting to manual and adding values for the file and directory mode creation mask:

```
cluster1::> vserver cifs share modify -vserver vs1 -share-name data1  
-offline-files manual -file-umask 644 -dir-umask 777  
  
cluster1::> vserver cifs share show -vserver vs1 -share-name data1  
-instance  
  
Vserver: vs1  
Share: data1  
CIFS Server NetBIOS Name: VS1  
Path: /data1  
Share Properties: oplocks  
browsable  
changenotify  
Symlink Properties: enable  
File Mode Creation Mask: 644  
Directory Mode Creation Mask: 777  
Share Comment: Offline files  
Share ACL: Everyone / Full Control  
File Attribute Cache Lifetime: -  
Volume Name: -  
Offline Files: manual  
Vscan File-Operations Profile: standard  
Maximum Tree Connections on Share: 4294967295  
UNIX Group for File Create: -
```

= Configure offline files support on SMB shares by using the Computer Management MMC

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you want to permit users to cache files locally for offline use, you can configure offline files support by using the Computer Management MMC (Microsoft Management Console).

Steps

1. To open the MMC on your Windows server, in Windows Explorer, right-click the icon for the local computer, and then select **Manage**.
2. On the left panel, select **Computer Management**.
3. Select **Action > Connect to another computer**.

The Select Computer dialog box appears.

- Type the name of the CIFS server or click **Browse** to locate the CIFS server.

If the name of CIFS server is the same as the storage virtual machine (SVM) host name, type the SVM name. If the CIFS server name is different from the SVM host name, type the name of the CIFS server.

- Click **OK**.
- In the console tree, click **System Tools > Shared Folders**.
- Click **Shares**.
- In the results pane, right-click the share.
- Click **Properties**.

Properties for the share you selected are displayed.

- In the **General** tab, click **Offline Settings**.

The Offline Settings dialog box appears.

- Configure the offline availability options as appropriate.

- Click **OK**.

- = Use roaming profiles to store user profiles centrally on a SMB server associated with the SVM
- = Use roaming profiles to store user profiles centrally on a SMB server associated with the SVM overview

ONTAP supports storing Windows roaming profiles on a CIFS server associated with the storage virtual machine (SVM). Configuring user roaming profiles provides advantages to the user such as automatic resource availability regardless of where the user logs in. Roaming profiles also simplify the administration and management of user profiles.

Roaming user profiles have the following advantages:

- Automatic resource availability

A user's unique profile is automatically available when that user logs in to any computer on the network that is running Windows 8, Windows 7, Windows 2000, or Windows XP. Users do not need to create a profile on each computer they use on a network.

- Simplified computer replacement

Because all of the user's profile information is maintained separately on the network, a user's profile can be easily downloaded onto a new, replacement computer. When the user logs in to the new computer for the first time, the server copy of the user's profile is copied to the new computer.

Using folder redirection to store data on a CIFS server

= Requirements for using roaming profiles

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Before you can use Microsoft's roaming profiles with your CIFS server, you need to know which versions of ONTAP and SMB and which Windows clients support the feature.

== ONTAP version requirements

ONTAP support roaming profiles.

== SMB protocol version requirements

For storage virtual machine (SVM), ONTAP supports roaming profiles on all versions of SMB.

== Windows client requirements

Before a user can use the roaming profiles, the Windows client must support the feature.

For the latest information about which Windows clients support roaming profiles, see the Interoperability Matrix.

NetApp Interoperability Matrix Tool

= Configure roaming profiles

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you want to automatically make a user's profile available when that user logs on to any computer on the network, you can configure roaming profiles through the Active Directory Users and Computers MMC snap-in. If you are configuring roaming profiles on Windows Server 2012, you can use the Active Directory Administration Center.

Steps

1. On the Windows server, open the Active Directory Users and Computers MMC (or the Active Directory Administration Center on Windows 2012 and later servers).
2. Locate the user for which you want to configure a roaming profile.
3. Right-click the user and click **Properties**.
4. On the **Profile** tab, enter the profile path to the share where you want to store the user's roaming profile, followed by %username%.

For example, a profile path might be the following: \\vs1.example.com\profiles\%username%. The first time a user logs in, %username% is replaced with the user's name.

In the path \\vs1.example.com\profiles\%username%, profiles is the share name of a share on storage virtual machine (SVM) vs1 that has Full Control rights for Everyone.

5. Click **OK**.

= Use folder redirection to store data on a SMB server

= Use folder redirection to store data on a SMB server overview

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ONTAP supports Microsoft folder redirection, which enables users or administrators to redirect the path of a local folder to a location on the CIFS server. It appears as if redirected folders are stored on the local Windows client, even though the data is stored on an SMB share.

Folder redirection is intended mostly for organizations that have already deployed home directories, and that want to maintain compatibility with their existing home directory environment.

- Documents, Desktop, and Start Menu are examples of folders that you can redirect.
- Users can redirect folders from their Windows client.
- Administrators can centrally configure and manage folder redirection by configuring GPOs in Active Directory.
- If administrators have configured roaming profiles, folder redirection enables administrators to divide user data from profile data.
- Administrators can use folder redirection and offline files together to redirect data storage for local folders to the CIFS server, while allowing users to cache the content locally.

[Microsoft TechNet Library: technet.microsoft.com/en-us/library/](https://technet.microsoft.com/en-us/library/)

= Access the `~snapshot` directory from Windows clients using SMB 2.x

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The method that you use to access the `~snapshot` directory from Windows clients using SMB 2.x differs from the method used for SMB 1.0. You need to understand how to access the `~snapshot` directory when using SMB 2.x connections to successfully access data stored in Snapshot copies.

The SVM administrator controls whether users on Windows clients can view and access the `~snapshot` directory on a share by enabling or disabling the `showsnapshot` share property using commands from the vserver cifs share properties families.

When the `showsnapshot` share property is disabled, a user on a Windows client using SMB 2.x cannot view the `~snapshot` directory and cannot access Snapshot copies within the `~snapshot` directory, even when manually entering the path to the `~snapshot` directory or to specific Snapshot copies within the directory.

When the `showsnapshot` share property is enabled, a user on a Windows client using SMB 2.x still cannot view the `~snapshot` directory either at the root of the share or within any junction or directory below the root of the share. However, after connecting to a share, the user can access the hidden `~snapshot` directory by manually appending `\~snapshot` to the end of the share path. The hidden `~snapshot` directory is accessible from two entry points:

- At the root of the share
- At every junction point in the share space

The hidden `~snapshot` directory is not accessible from non-junction subdirectories within the share.

Example

With the configuration shown in the following example, a user on a Windows client with an SMB 2.x connection to the “eng” share can access the `~snapshot` directory by manually appending `\~snapshot` to the share path at the root of the share and at every junction point in the path. The hidden `~snapshot` directory is accessible from the following three paths:

- `\vs1\eng\~snapshot`
- `\vs1\eng\projects1\~snapshot`
- `\vs1\eng\projects2\~snapshot`

```
cluster1::> volume show -vserver vs1 -fields volume,junction-path
vserver volume      junction-path
-----
vs1    vs1_root      /
vs1    vs1_voll      /eng
vs1    vs1_vol2      /eng/projects1
vs1    vs1_vol3      /eng/projects2

cluster1::> vserver cifs share show
Vserver Share   Path     Properties      Comment   ACL
-----
vs1    eng       /eng     oplocks        -         Everyone / Full
Control
                           changenotify
                           browsable
                           showsnapshot
```

= Recover files and folders using Previous Versions

= Recover files and folders using previous versions overview

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The ability to use Microsoft Previous Versions is applicable to file systems that support Snapshot copies in some form and have them enabled. Snapshot technology is an integral part of ONTAP. Users can recover files and folders from Snapshot copies from their Windows client by using the Microsoft Previous Versions feature.

Previous Versions functionality provides a method for users to browse through the Snapshot copies or to restore data from a Snapshot copy without a storage administrator's intervention. Previous Versions is not configurable. It is always enabled. If the storage administrator has made Snapshot copies available on a share, then the user can use Previous Versions to perform the following tasks:

- Recover files that were accidentally deleted.
- Recover from accidentally overwriting a file.
- Compare versions of file while working.

The data stored in Snapshot copies is read-only. Users must save a copy of a file to another location to make any changes to the file. Snapshot copies are periodically deleted; therefore, users need to create copies of files contained in Previous Versions if they want to indefinitely retain a previous version of a file.

= Requirements for using Microsoft Previous Versions

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Before you can use Previous Versions with your CIFS server, you need to know which versions of ONTAP and SMB, and which Windows clients, support it. You also need to know about the Snapshot copy setting requirement.

== ONTAP version requirements

Supports Previous Versions.

== SMB protocol version requirements

For storage virtual machine (SVM), ONTAP supports Previous Versions on all versions of SMB.

== Windows client requirements

Before a user can use Previous Versions to access data in Snapshot copies, the Windows client must support the feature.

For the latest information about which Windows clients support Previous Versions, see the Interoperability Matrix.

[NetApp Interoperability Matrix Tool](#)

== Requirements for Snapshot copy settings

To use Previous Versions to access data in Snapshot copies, an enabled Snapshot policy must be associated to the volume containing the data, clients must be able to access to the Snapshot data, and Snapshot copies must exist.

= Use the Previous Versions tab to view and manage Snapshot copy data

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Users on Windows client machines can use the Previous Versions tab on the Windows Properties window to restore data stored in Snapshot copies without needing to involve the storage virtual machine (SVM) administrator.

About this task

You can only use the Previous Versions tab to view and manage data in Snapshot copies of data stored on the SVM if the administrator has enabled Snapshot copies on the volume containing the share, and if the administrator configures the share to show Snapshot copies.

Steps

1. In Windows Explorer, display the contents of the mapped drive of the data stored on the CIFS server.
2. Right-click the file or folder in the mapped network drive whose Snapshot copies you want to view or manage.
3. Click **Properties**.

Properties for the file or folder you selected are displayed.

4. Click the **Previous Versions** tab.

A list of available Snapshot copies of the selected file or folder is displayed in the **Folder versions:** box. The listed Snapshot copies are identified by the Snapshot copy name prefix and the creation timestamp.

5. In the **Folder versions:** box, right-click the copy of the file or folder that you want to manage.
6. Perform the appropriate action:

If you want to...	Do the following...
View data from that Snapshot copy	Click Open .
Create a copy of data from that Snapshot copy	Click Copy .

Data in Snapshot copies is read-only. If you want to make modifications to files and folders listed in the Previous Versions tab, you must save a copy of the files and folders that you want to modify to a writable location and make modifications to the copies.

7. After you finish managing Snapshot data, close the **Properties** dialog box by clicking **OK**.

For more information about using the Previous Versions tab to view and manage Snapshot data, consult the Microsoft TechNet Library.

Related information

[Microsoft TechNet Library: technet.microsoft.com/en-us/library/](https://technet.microsoft.com/en-us/library)

= Determine whether Snapshot copies are available for Previous Versions use

:icons: font

```
:relative_path: ./smb-admin/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

You can view Snapshot copies from the Previous Versions tab only if an enabled Snapshot policy is applied to the volume containing the share, and if the volume configuration allows access to Snapshot copies. Determining Snapshot copy availability is helpful when assisting a user with Previous Versions access.

Steps

1. Determine whether the volume on which the share data resides has automatic Snapshot copies enabled and whether clients have access to Snapshot directories: `volume show -vserver vserver-name -volume volume-name -fields vserver, volume, snapdir-access, snapshot-policy, snapshot-count`

The output displays what Snapshot policy is associated with the volume, whether client Snapshot directory access is enabled, and the number of available Snapshot copies.

2. Determine whether the associated Snapshot policy is enabled: `volume snapshot policy show -policy policy-name`
3. List the available Snapshot copies: `volume snapshot show -volume volume_name`

For more information about configuring and managing Snapshot policies and Snapshot schedules, see [Data Protection](#).

Example

The following example displays information about Snapshot policies associated with the volume named “data1” that contains the shared data and available Snapshot copies on “data1”.

```
cluster1::> volume show -vserver vs1 -volume data1 -fields  
vserver, volume, snapshot-policy, snapdir-access, snapshot-count  
vserver      volume      snapdir-access      snapshot-policy      snapshot-count  
-----  
vs1          data1        true            default           10  
  
cluster1::> volume snapshot policy show -policy default  
Vserver: cluster1  
          Number of Is  
Policy Name      Schedules Enabled Comment  
-----  
default          3  true    Default policy with hourly, daily  
& weekly schedules.  
          Schedule      Count      Prefix      SnapMirror Label

[Creating a Snapshot configuration to enable Previous Versions access](#)

Data protection

= Create a Snapshot configuration to enable Previous Versions access

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

The Previous Versions functionality is always available, provided that client access to Snapshot copies is enabled and provided that Snapshot copies exist. If your Snapshot copy configuration does not meet these requirements, you can create a Snapshot copy configuration that does.

Steps

1. If the volume containing the share to which you want to allow Previous Versions access does not have an associated Snapshot policy, associate a Snapshot policy to the volume and enable it by using

the `volume modify` command.

For more information about using the `volume modify` command, see the man pages.

2. Enable access to the Snapshot copies by using the `volume modify` command to set the `-snap-dir` option to `true`.

For more information about using the `volume modify` command, see the man pages.

3. Verify that Snapshot policies are enabled and that access to Snapshot directories is enabled by using the `volume show` and `volume snapshot policy show` commands.

For more information about using the `volume show` and `volume snapshot policy show` commands, see the man pages.

For more information about configuring and managing Snapshot policies and Snapshot schedules, see [Data Protection](#).

[Data protection](#)

= Guidelines for restoring directories that contain junctions

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

There are certain guidelines you should keep in mind when using Previous Versions to restore folders that contain junction points.

When using Previous Versions to restore folders that have child folders that are junction points, the restore can fail with an Access Denied error.

You can determine whether the folder that you are attempting to restore contains a junction by using the `vol show` command with the `-parent` option. You can also use the `vserver security trace` commands to create detailed logs about file and folder access issues.

= Deploy SMB server-based services

= Manage home directories

= How ONTAP enables dynamic home directories

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ONTAP home directories enable you to configure an SMB share that maps to different directories based on the user that connects to it and a set of variables.

Instead of creating separate shares for each user, you can configure one share with a few home directory parameters to define a user's relationship between an entry point

(the share) and the home directory (a directory on the SVM).

A user who is logged in as a guest user does not have a home directory and cannot access other users' home directories. There are four variables that determine how a user is mapped to a directory:

- **Share name**

This is the name of the share that you create to which the user connects. You must set the home directory property for this share.

The share name can use the following dynamic names:

- %w (the user's Windows user name)
- %d (the user's Windows domain name)
- %u (the user's mapped UNIX user name)

To make the share name unique across all home directories, the share name must contain either the %w or the %u variable. The share name can contain both the %d and the %w variable (for example, %d/%w), or the share name can contain a static portion and a variable portion (for example, home_%w).

- **Share path**

This is the relative path, which is defined by the share and is therefore associated with one of the share names, that is appended to each search path to generate the user's entire home directory path from the root of the SVM. It can be static (for example, home), dynamic (for example, %w), or a combination of the two (for example, eng/%w).

- **Search paths**

This is the set of absolute paths from the root of the SVM that you specify that directs the ONTAP search for home directories. You can specify one or more search paths by using the vserver cifs home-directory search-path add command. If you specify multiple search paths, ONTAP tries them in the order specified until it finds a valid path.

- **Directory**

This is the user's home directory that you create for the user. The directory name is usually the user's name. You must create the home directory in one of the directories that are defined by the search paths.

As an example, consider the following setup:

- User: John Smith
- User domain: acme
- User name: jsmith
- SVM name: vs1
- Home directory share name #1: home_%w - share path: %w
- Home directory share name #2: %w - share path: %d/%w
- Search path #1: /vol0/home/home
- Search path #2: /vol1/home/home

- Search path #3: /vol2home/home
- Home directory: /vol1home/home/jsmith

Scenario 1: The user connects to \\vs1\home_jsmith. This matches the first home directory share name and generates the relative path jsmith. ONTAP now searches for a directory named jsmith by checking each search path in order:

- /vol0home/home/jsmith does not exist; moving on to search path #2.
- /vol1home/home/jsmith does exist; therefore, search path #3 is not checked; the user is now connected to his home directory.

Scenario 2: The user connects to \\vs1\jsmith. This matches the second home directory share name and generates the relative path acme/jsmith. ONTAP now searches for a directory named acme/jsmith by checking each search path in order:

- /vol0home/home/acme/jsmith does not exist; moving on to search path #2.
- /vol1home/home/acme/jsmith does not exist; moving on to search path #3.
- /vol2home/home/acme/jsmith does not exist; the home directory does not exist; therefore, the connection fails.

= Home directory shares

= Add a home directory share

```
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

If you want to use the SMB home directory feature, you must add at least one share with the home directory property included in the share properties.

About this task

You can create a home directory share at the time you create the share by using the vserver cifs share create command, or you can change an existing share into a home directory share at any time by using the vserver cifs share modify command.

To create a home directory share, you must include the homedirectory value in the –share-properties option when you create or modify a share. You can specify the share name and share path using variables that are dynamically expanded when users connect to their home directories. Available variables that you can use in the path are %w, %d, and %u, corresponding to the Windows user name, domain, and mapped UNIX user name, respectively.

Steps

1. Add a home directory share:

```
vserver cifs share create -vserver vserver_name -share-name share_name
-path path -share-properties homedirectory[,...]
```

–vserver vserver specifies the CIFS-enabled storage virtual machine (SVM) on which to add the search path.

–share-name share-name specifies the home directory share name.

In addition to containing one of the required variables, if the share name contains one of the literal strings %w, %u, or %d, you must precede the literal string with a % (percent) character to prevent ONTAP from treating the literal string as a variable (for example, %%w).

- The share name must contain either the %w or the %u variable.
- The share name can additionally contain the %d variable (for example, %d/%w) or a static portion in the share name (for example, home1_%w).
- If the share is used by administrators to connect to other users' home directories or to permit users to connect to other users' home directories, the dynamic share name pattern must be preceded by a tilde (~).

The vserver cifs home-directory modify is used to enable this access by setting the -is-home-dirs-access-for-admin-enabled option to true) or by setting the advanced option -is-home-dirs-access-for-public-enabled to true.

-path path specifies the relative path to the home directory.

-share-properties homedirectory[,...] specifies the share properties for that share. You must specify the homedirectory value. You can specify additional share properties using a comma delimited list.

1. Verify that you successfully added the home directory share by using the vserver cifs share show command.

Example

The following command creates a home directory share named %w. The oplocks, browsable, and changenotify share properties are set in addition to setting the homedirectory share property.

This example does not display output for all of the shares on the SVM. Output is truncated.

```
cluster1::> vserver cifs share create -vserver vs1 -share-name %w -path %w -share-properties oplocks,browsable,changedirectory

vs1::> vserver cifs share show -vserver vs1
Vserver      Share      Path          Properties        Comment    ACL
-----      -----      -----          -----        -----
vs1          %w          %w            oplocks        -
                                         browsable
                                         changedirectory
                                         homedirectory
```

Related information

[Adding a home directory search path](#)

[Requirements and guidelines for using automatic node referrals](#)

[Managing accessibility to users' home directories](#)

= Home directory shares require unique user names
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Be careful to assign unique user names when creating home directory shares using the %w (Windows user name) or %u (UNIX user name) variables to generate shares dynamically. The share name is mapped to your user name.

Two problems can occur when a static share's name and a user's name are the same:

- When the user lists the shares on a cluster using the net view command, two shares with the same user name are displayed.
- When the user connects to that share name, the user is always connected to the static share and cannot access the home directory share with the same name.

For example, there is a share named "administrator" and you have an "administrator" Windows user name. If you create a home directory share and connect to that share, you get connected to the "administrator" static share, not to your "administrator" home directory share.

You can resolve the issue with duplicate share names by following any of these steps:

- Renaming the static share so that it no longer conflicts with the user's home directory share.
- Giving the user a new user name so that it no longer conflicts with the static share name.
- Creating a CIFS home directory share with a static name such as "home" instead of using the %w parameter to avoid conflicts with the share names.

= What happens to static home directory share names after upgrading
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Home directory share names must contain either the %w or the %u dynamic variable. You should be aware of what happens to existing static home directory share names after upgrading to a version of ONTAP with the new requirement.

If your home directory configuration contains static share names and you upgrade to ONTAP, the static home directory share names are not changed and are still valid. However, you cannot create any new home directory shares that do not contain either the %w or %u variable.

Requiring that one of these variables is included in the user's home directory share name ensures that every share name is unique across the home directory configuration. If desired, you can change the static home directory share names to names that contain either the %w or %u variable.

= Add a home directory search path
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you want to use ONTAP SMB home directories, you must add at least one home directory search path.

About this task

You can add a home directory search path by using the `vserver cifs home-directory search-path add` command.

The `vserver cifs home-directory search-path add` command checks the path specified in the `-path` option during command execution. If the specified path does not exist, the command generates a message prompting for whether you want to continue. You choose `y` or `n`. If you choose `y` to continue, ONTAP creates the search path. However, you must create the directory structure before you can use the search path in the home directory configuration. If you choose not to continue, the command fails; the search path is not created. You can then create the path directory structure and rerun the `vserver cifs home-directory search-path add` command.

Steps

1. Add a home directory search path: `vserver cifs home-directory search-path add -vserver vserver -path path`
2. Verify that you successfully added the search path using the `vserver cifs home-directory search-path show` command.

Example

The following example adds the path `/home1` to the home directory configuration on SVM `vs1`.

```
cluster::> vserver cifs home-directory search-path add -vserver vs1  
-path /home1  
  
vs1::> vserver cifs home-directory search-path show  
Vserver      Position Path  
-----  
vs1          1            /home1
```

The following example attempts to add the path `/home2` to the home directory configuration on SVM `vs1`. The path does not exist. The choice is made to not continue.

```
cluster::> vserver cifs home-directory search-path add -vserver vs1  
-path /home2  
Warning: The specified path "/home2" does not exist in the namespace  
belonging to Vserver "vs1".  
Do you want to continue? {y|n}: n
```

Related information

[Adding a home directory share](#)

= Create a home directory configuration using the `%w` and `%d` variables
:icons: font
:relative_path: `./smb-admin/`
:imagesdir: `/tmp/d20220215-32410-h8nxng/source./smb-admin/..media/`

You can create a home directory configuration using the %w and %d variables. Users can then connect to their home share using dynamically created shares.

Steps

1. Create a qtree to contain user's home directories: `volume qtree create -vserver vserver_name -qtree-path qtree_path`
2. Verify that the qtree is using the correct security style: `volume qtree show`
3. If the qtree is not using the desired security style, change the security style using the `volume qtree security` command.
4. Add a home directory share: `vserver cifs share create -vserver vserver -share -name %w -path %d/%w -share-properties homedirectory\[,...\]`
-vserver `vserver` specifies the CIFS-enabled storage virtual machine (SVM) on which to add the search path.
-share-name `%w` specifies the home directory share name. ONTAP dynamically creates the share name as each user connects to their home directory. The share name will be of the form `windows_user_name`.
-path `%d/%w` specifies the relative path to the home directory. The relative path is dynamically created as each user connects to their home directory and will be of the form `domain/windows_user_name`.
-share-properties `homedirectory[,...]` specifies the share properties for that share. You must specify the `homedirectory` value. You can specify additional share properties using a comma delimited list.
5. Verify that the share has the desired configuration using the `vserver cifs share show` command.
6. Add a home directory search path: `vserver cifs home-directory search-path add -vserver vserver -path path`
-vserver `vserver-name` specifies the CIFS-enabled SVM on which to add the search path.
-path `path` specifies the absolute directory path to the search path.
7. Verify that you successfully added the search path using the `vserver cifs home-directory search-path show` command.
8. For users with a home directory, create a corresponding directory in the qtree or volume designated to contain home directories.

For example, if you created a qtree with the path of `/vol/vol1/users` and the user name whose directory you want to create is `mydomain\user1`, you would create a directory with the following path: `/vol/vol1/users/mydomain/user1`.

If you created a volume named "home1" mounted at `/home1`, you would create a directory with the following path: `/home1/mydomain/user1`.
9. Verify that a user can successfully connect to the home share either by mapping a drive or connecting using the UNC path.

For example, if user mydomain\user1 wants to connect to the directory created in Step 8 that is located on SVM vs1, user1 would connect using the UNC path \\vs1\user1.

Example

The commands in the following example create a home directory configuration with the following settings:

- The share name is %w.
- The relative home directory path is %d/%w.
- The search path that is used to contain the home directories, /home1, is a volume configured with NTFS security style.
- The configuration is created on SVM vs1.

You can use this type of home directory configuration when users access their home directories from Windows hosts. You can also use this type of configuration when users access their home directories from Windows and UNIX hosts and the file system administrator uses Windows-based users and groups to control access to the file system.

```

cluster::> vserver cifs share create -vserver vs1 -share-name %w -path
%d/%w -share-properties oplocks,browsable,changetrigger,homedirectory

cluster::> vserver cifs share show -vserver vs1 -share-name %w

          Vserver: vs1
          Share: %w
CIFS Server NetBIOS Name: VS1
          Path: %d/%w
Share Properties: oplocks
                  browsable
                  changetrigger
                  homedirectory
Symlink Properties: enable
File Mode Creation Mask: -
Directory Mode Creation Mask: -
Share Comment: -
Share ACL: Everyone / Full Control
File Attribute Cache Lifetime: -
Volume Name: -
Offline Files: manual
Vscan File-Operations Profile: standard

cluster::> vserver cifs home-directory search-path add -vserver vs1

[Configuring home directories using the %u variable](#)

[Additional home directory configurations](#)

[Displaying information about an SMB user's home directory path](#)

= Configure home directories using the %u variable

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can create a home directory configuration where you designate the share name using the %w variable but you use the %u variable to designate the relative path to the home directory share. Users can then connect to their home share using dynamically

shares created using their Windows user name without being aware of the actual name or path of the home directory.

Steps

1. Create a qtree to contain user's home directories: `volume qtree create -vserver vserver_name -qtree-path qtree_path`
2. Verify that the qtree is using the correct security style: `volume qtree show`
3. If the qtree is not using the desired security style, change the security style using the `volume qtree security` command.
4. Add a home directory share: `vserver cifs share create -vserver vserver -share -name %w -path %u -share-properties homedirectory ,...]`
-vserver vserver specifies the CIFS-enabled storage virtual machine (SVM) on which to add the search path.
-share-name %w specifies the home directory share name. The share name is dynamically created as each user connects to their home directory and is of the form `windows_user_name`.

You can also use the %u variable for the -share-name option. This creates a relative share path that uses the mapped UNIX user name.

-path %u specifies the relative path to the home directory. The relative path is created dynamically as each user connects to their home directory and is of the form `mapped_UNIX_user_name`.

The value for this option can contain static elements as well. For example, eng/%u.

-share-properties homedirectory\[,...\] specifies the share properties for that share. You must specify the homedirectory value. You can specify additional share properties using a comma delimited list.

5. Verify that the share has the desired configuration using the `vserver cifs share show` command.
6. Add a home directory search path: `vserver cifs home-directory search-path add -vserver vserver -path path`
-vserver vserver specifies the CIFS-enabled SVM on which to add the search path.
-path path specifies the absolute directory path to the search path.
7. Verify that you successfully added the search path using the `vserver cifs home-directory search-path show` command.
8. If the UNIX user does not exist, create the UNIX user using the `vserver services unix-user create` command.

The UNIX user name to which you map the Windows user name must exist before mapping the user.

9. Create a name mapping for the Windows user to the UNIX user using the following command:

```
vserver name-mapping create -vserver vserver_name -direction win-unix  
-priority integer -pattern windows_user_name -replacement unix_user_name
```

If name mappings already exist that map Windows users to UNIX users, you do not have to perform the mapping step.

The Windows user name is mapped to the corresponding UNIX user name. When the Windows user connects to their home directory share, they connect to a dynamically created home directory with a share name that corresponds to their Windows user name without being aware that the directory name corresponds to the UNIX user name.

10. For users with a home directory, create a corresponding directory in the qtree or volume designated to contain home directories.

For example, if you created a qtree with the path of /vol/vol1/users and the mapped UNIX user name of the user whose directory you want to create is “unixuser1”, you would create a directory with the following path: /vol/vol1/users/unixuser1.

If you created a volume named “home1” mounted at /home1, you would create a directory with the following path: /home1/unixuser1.

11. Verify that a user can successfully connect to the home share either by mapping a drive or connecting using the UNC path.

For example, if user mydomain\user1 maps to UNIX user unixuser1 and wants to connect to the directory created in Step 10 that is located on SVM vs1, user1 would connect using the UNC path \\vs1\user1.

Example

The commands in the following example create a home directory configuration with the following settings:

- The share name is %w.
- The relative home directory path is %u.
- The search path that is used to contain the home directories, /home1, is a volume configured with UNIX security style.
- The configuration is created on SVM vs1.

You can use this type of home directory configuration when users access their home directories from both Windows hosts or Windows and UNIX hosts and the file system administrator uses UNIX-based users and groups to control access to the file system.

```

cluster::> vserver cifs share create -vserver vs1 -share-name %w -path
%u -share-properties oplocks,browsable,changeNotify,homedirectory

cluster::> vserver cifs share show -vserver vs1 -share-name %u

          Vserver: vs1
          Share: %w
CIFS Server NetBIOS Name: VS1
          Path: %u
Share Properties: oplocks
                  browsable
                  changeNotify
                  homedirectory
Symlink Properties: enable
File Mode Creation Mask: -
Directory Mode Creation Mask: -
Share Comment: -

[Creating a home directory configuration using the %w and %d variables](#)

[Additional home directory configurations](#)

[Displaying information about an SMB user's home directory path](#)

```
= Additional home directory configurations
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

You can create additional home directory configurations using the %w, %d, and %u variables, which enables you to customize the home directory configuration to meet your needs.

You can create a number of home directory configurations using a combination of variables and static strings in the share names and search paths. The following table provides some examples illustrating how to create different home directory configurations:

Paths created when /vol1/user contains home directories...	Share command...
To create a share path \\vs1\~win_username that directs the user to /vol1/user/win_username	vserver cifs share create -share-name ~%w -path %w -share-properties oplocks,browsable,changeNotify,homedirectory
To create a share path \\vs1\win_username that directs the user to /vol1/user/domain/win_username	vserver cifs share create -share-name %w -path %d/%w -share-properties oplocks,browsable,changeNotify,homedirectory
To create a share path \\vs1\win_username that directs the user to /vol1/user/unix_username	vserver cifs share create -share-name %w -path %u -share-properties oplocks,browsable,changeNotify,homedirectory
To create a share path \\vs1\unix_username that directs the user to /vol1/user/unix_username	vserver cifs share create -share-name %u -path %u -share-properties oplocks,browsable,changeNotify,homedirectory

```
= Commands for managing search paths
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

There are specific ONTAP commands for managing search paths for SMB home directory configurations. For example, there are commands for adding, removing, and displaying information about search paths. There is also a command for changing the search path order.

If you want to...	Use this command...
Add a search path	vserver cifs home-directory search-path add
Display search paths	vserver cifs home-directory search-path show
Change the search path order	vserver cifs home-directory search-path reorder
Remove a search path	vserver cifs home-directory search-path remove

See the man page for each command for more information.

= Display information about an SMB user's home directory path
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can display an SMB user's home directory path on the storage virtual machine (SVM), which can be used if you have multiple CIFS home directory paths configured and you want to see which path holds the user's home directory.

Step

1. Display the home directory path by using the vserver cifs home-directory show-user command.

```
vserver cifs home-directory show-user -vserver vs1 -username user1
```

Vserver	User	Home Dir Path
vs1	user1	/home/user1

Related information

[Managing accessibility to users' home directories](#)

= Manage accessibility to users' home directories
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

By default, a user's home directory can be accessed only by that user. For shares where the dynamic name of the share is preceded with a tilde (~), you can enable or disable access to users' home directories by Windows administrators or by any other user (public access).

Before you begin

Home directory shares on the storage virtual machine (SVM) must be configured with dynamic share names that are preceded with a tilde (~). The following cases illustrate share naming requirements:

Home directory share name	Example of command to connect to the share
~%d~%w	net use * \\IPaddress\~domain~user/u:credentials
~%w	net use * \\IPaddress\~user/u:credentials
~abc~%w	net use * \\IPaddress\abc~user/u:credentials

Step

1. Perform the appropriate action:

If you want to enable or disable access to users' home directories to...	Enter the following...
Windows administrators	vserver cifs home-directory modify -vserver vserver_name -is-home-dirs-access-for-admin-enabled {true false} The default is true.
Any user (public access)	a. Set the privilege level to advanced: set -privilege advanced b. Enable or disable access: vserver cifs home-directory modify -vserver vserver_name -is-home-dirs-access-for-public-enabled {true false} The default is false. c. Return to the admin privilege level: set -privilege admin

The following example enables public access to users' home directories:

```
set -privilege advanced
vserver cifs home-directory modify -vserver vs1 -is-home-dirs-access-for-public-enabled true
set -privilege admin
```

= Configure SMB client access to UNIX symbolic links

= How ONTAP enables you to provide SMB client access to UNIX symbolic links

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..../media/

A symbolic link is a file that is created in a UNIX environment that contains a reference to another file or directory. If a client accesses a symbolic link, the client is redirected to the target file or directory to which the symbolic link refers. ONTAP supports relative and absolute symbolic links, including *widelinks* (absolute links with targets outside the local file system).

ONTAP provides SMB clients the ability to follow UNIX symbolic links that are configured on the SVM. This feature is optional, and you can configure it on a per-share basis, using the `-symlink -properties` option of the `vserver cifs share create` command, with one of the following settings:

- Enabled with read/write access
- Enabled with read-only access
- Disabled by hiding symbolic links from SMB clients
- Disabled with no access to symbolic links from SMB clients

If you enable symbolic links on a share, relative symbolic links work without further configuration.

If you enable symbolic links on a share, absolute symbolic links do not work right away. You must first create a mapping between the UNIX path of the symbolic link to the destination SMB path. When creating absolute symbolic link mappings, you can specify whether it is a local link or a *widelink*; *widelinks* can be links to file systems on other storage devices or links to file systems hosted in separate SVMs on the same ONTAP system. When you create a *widelink*, it must include the information for the client to follow; that is, you create a reparse point for the client to discover the directory junction point. If you create an absolute symbolic link to a file or directory outside of the local share but set the locality to local, ONTAP disallows access to the target.

If a client attempts to delete a local symbolic link (absolute or relative), only the symbolic link is deleted, not the target file or directory. However, if a client attempts to delete a *widelink*, it might delete the actual target file or directory to which the *widelink* refers. ONTAP does not have control over this because the client can explicitly open the target file or directory outside the SVM and delete it.

- **Reparse points and ONTAP file system services**

A *reparse point* is an NTFS file system object that can be optionally stored on volumes along with a file. Reparse points provide SMB clients the ability to receive enhanced or extended file system services when working with NTFS style volumes. Reparse points consist of standard tags that identify the type of reparse point, and the content of the reparse point that can be retrieved by SMB clients for further processing by the client. Of the object types available for extended file system functionality, ONTAP implements support for NTFS symbolic links and directory junction points using reparse point tags. SMB clients that cannot understand the contents of a reparse point simply ignore it and don't provide the extended file system service that the reparse point might enable.

- **Directory junction points and ONTAP support for symbolic links**

Directory junction points are locations within a file system directory structure that can refer to alternate

locations where files are stored, either on a different path (symbolic links) or a separate storage device (widelinks). ONTAP SMB servers expose directory junction points to Windows clients as reparse points, allowing capable clients to obtain reparse point contents from ONTAP when a directory junction point is traversed. They can thereby navigate and connect to different paths or storage devices as though they were part of the same file system.

- **Enabling widelink support using reparse point options**

The `-is-use-junctions-as-reparse-points-enabled` option is enabled by default in ONTAP 9. Not all SMB clients support widelinks, so the option to enable the information is configurable on a per-protocol version basis, allowing administrators to accommodate both supported and non-supported SMB clients. In ONTAP 9.2 and later releases, you must enable the option `-widelink-as-reparse-point-versions` for each client protocol that accesses the share using widelinks; the default is SMB1. In earlier releases, only widelinks accessed using the default SMB1 were reported, and systems using SMB2 or SMB3 were unable to access the widelinks.

For more information, see the Microsoft NTFS documentation.

[Microsoft Documentation: Reparse Points](#)

= Limits when configuring UNIX symbolic links for SMB access

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..../media/

You need to be aware of certain limits when configuring UNIX symbolic links for SMB access.

Limit	Description
45	<p>Maximum length of the CIFS server name that you can specify when using an FQDN for the CIFS server name.</p> <p> You can alternatively specify the CIFS server name as a NetBIOS name, which is limited to 15 characters.</p>
80	Maximum length of the share name.
256	Maximum length of the UNIX path that you can specify when creating a symbolic link or when modifying an existing symbolic link's UNIX path. The UNIX path must start with a "/" (slash) and end with a "/". Both the beginning and ending slashes count as part of the 256-character limit.

Limit	Description
256	Maximum length of the CIFS path that you can specify when creating a symbolic link or when modifying an existing symbolic link's CIFS path. The CIFS path must start with a "/" (slash) and end with a "/". Both the beginning and ending slashes count as part of the 256-character limit.

[Creating symbolic link mappings for SMB shares](#)

= Control automatic DFS advertisements in ONTAP with a CIFS server option

```
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

A CIFS server option controls how DFS capabilities are advertised to SMB clients when connecting to shares. Because ONTAP uses DFS referrals when clients access symbolic links over SMB, you should be aware of what the impact is when disabling or enabling this option.

A CIFS server option determines whether the CIFS servers automatically advertise that they are DFS capable to SMB clients. By default, this option is enabled and the CIFS server always advertises that it is DFS capable to SMB clients (even when connecting to shares where access to symbolic links is disabled). If you want the CIFS server to advertise that it is DFS capable to clients only when they are connecting to shares where access to symbolic links is enabled, you can disable this option.

You should be aware of what happens when this option is disabled:

- The share configurations for symbolic links is unchanged.
- If the share parameter is set to allow symbolic link access (either read-write access or read-only access), the CIFS server advertises DFS capabilities to clients connecting to that share.

Client connections and access to symbolic links continue without interruption.

- If the share parameter is set to not allow symbolic link access (either by disabling access or if the value for the share parameter is null), the CIFS server does not advertise DFS capabilities to clients connecting to that share.

Because clients have cached information that the CIFS server is DFS capable and it is no longer advertising that it is, clients that are connected to shares where symbolic link access is disabled might not be able to access these shares after the CIFS server option is disabled. After the option is disabled, you might need to reboot clients that are connected to these shares, thus clearing the cached information.

These changes do not apply to SMB 1.0 connections.

= Configure UNIX symbolic link support on SMB shares

```
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

You can configure UNIX symbolic link support on SMB shares by specifying a symbolic link share-property setting when you create SMB shares or at any time by modifying existing SMB shares. UNIX symbolic link support is enabled by default. You can also disable UNIX symbolic link support on a share.

About this task

When configuring UNIX symbolic link support for SMB shares, you can choose one of the following settings:

Setting	Description
enable (DEPRECATED*)	Specifies that symbolic links are enabled for read-write access.
read_only (DEPRECATED*)	Specifies that symlinks are enabled for read-only access. This setting does not apply to widelinks. Widelink access is always read-write.
hide (DEPRECATED*)	Specifies that SMB clients are prevented from seeing symlinks.
no-strict-security	Specifies that clients follow symlinks outside of share boundaries.
symlinks	Specifies that symlinks are enabled locally for read-write access. The DFS advertisements are not generated even if the CIFS option <code>is-advertise-dfs-enabled</code> is set to <code>true</code> . This is the default setting.
symlinks-and-widelinks	Specifies that both local symlinks and widelinks for read-write access. The DFS advertisements are generated for both local symlink and widelinks even if the CIFS option <code>is-advertise-dfs-enabled</code> is set to <code>false</code> .
disable	Specifies that symlinks and widelinks are disabled. The DFS advertisements are not generated even if the CIFS option <code>is-advertise-dfs-enabled</code> is set to <code>true</code> .
"" (null, not set)	Disables symbolic links on the share.
- (not set)	Disables symbolic links on the share.

*The `enable`, `hide`, and `read-only` parameters are deprecated and may be removed in a future release of ONTAP.

Steps

1. Configure or disable symbolic link support:

If it is...	Enter...
A new SMB share	vserver cifs share create -vserver vserver_name -share-name share_name -path path -symlink-properties {enable hide read-only " " - symlinks symlinks-and-widelinks disable},...]
An existing SMB share	vserver cifs share modify -vserver vserver_name -share-name share_name -symlink-properties {enable hide read-only " " - symlinks symlinks-and-widelinks disable},...]

2. Verify that the SMB share configuration is correct: `vserver cifs share show -vserver vserver_name -share-name share_name -instance`

Example

The following command creates an SMB share named “data1” with the UNIX symbolic link configuration set to enable:

```

cluster1::> vserver cifs share create -vserver vs1 -share-name data1
-path /data1 -symlink-properties enable

cluster1::> vserver cifs share show -vserver vs1 -share-name data1
-instance

          Vserver: vs1
          Share: data1
          CIFS Server NetBIOS Name: VS1
          Path: /data1
          Share Properties: oplocks
                           browsable
                           changenotify
          Symlink Properties: enable
          File Mode Creation Mask: -
          Directory Mode Creation Mask: -
          Share Comment: -
          Share ACL: Everyone / Full Control
          File Attribute Cache Lifetime: -
          Volume Name: -
          Offline Files: manual
          Vscan File-Operations Profile: standard
          Maximum Tree Connections on Share: 4294967295
          UNIX Group for File Create: -

```

[Creating symbolic link mappings for SMB shares](#)

= Create symbolic link mappings for SMB shares

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can create mappings of UNIX symbolic links for SMB shares. You can either create a relative symbolic link, which refers to the file or folder relative to its parent folder, or you can create an absolute symbolic link, which refers to the file or folder using an absolute path.

About this task

Widelinks are not accessible from Mac OS X clients if you use SMB 2.x. When a user attempts to connect to a share using widelinks from a Mac OS X client, the attempt fails. However, you can use widelinks with Mac OS X clients if you use SMB 1.

Steps

1. To create symbolic link mappings for SMB shares: `vserver cifs symlink create -vserver virtual_server_name -unix-path path -share-name share_name -cifs-path path [-cifs-server server_name] [-locality {local|free|widelink}] [-home-`

`directory {true|false}]`

`-vserver virtual_server_name` specifies the storage virtual machine (SVM) name.

`-unix-path path` specifies the UNIX path. The UNIX path must begin with a slash (/) and must end with a slash (/).

`-share-name share_name` specifies the name of the SMB share to map.

`-cifs-path path` specifies the CIFS path. The CIFS path must begin with a slash (/) and must end with a slash (/).

`-cifs-server server_name` specifies the CIFS server name. The CIFS server name can be specified as a DNS name (for example, mynetwork.cifs.server.com), IP address, or NetBIOS name. The NetBIOS name can be determined by using the `vserver cifs show` command. If this optional parameter is not specified, the default value is the NetBIOS name of the local CIFS server.

`-locality {local|free|widelink}` specifies whether to create a local link, a free link or a wide symbolic link. A local symbolic link maps to the local SMB share. A free symbolic link can map anywhere on the local SMB server. A wide symbolic link maps to any SMB share on the network. If you do not specify this optional parameter, the default value is `local`.

`-home-directory {true|false}` specifies whether the target share is a home directory. Even though this parameter is optional, you must set this parameter to `true` when the target share is configured as a home directory. The default is `false`.

Example

The following command creates a symbolic link mapping on the SVM named vs1. It has the UNIX path `/src/`, the SMB share name “`SOURCE`”, the CIFS path `/mycompany/source/`, and the CIFS server IP address `123.123.123.123`, and it is a widelink.

```
cluster1::> vserver cifs symlink create -vserver vs1 -unix-path /src/
-share-name SOURCE -cifs-path "/mycompany/source/" -cifs-server
123.123.123.123 -locality widelink
```

= Use BranchCache to cache SMB share content at a branch office

= Use BranchCache to cache SMB share content at a branch office overview

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

BranchCache was developed by Microsoft to enable caching of content on computers local to requesting clients. ONTAP implementation of BranchCache can reduce wide-area network (WAN) utilization and provide improved access response time when users in a branch office access content stored on storage virtual machines (SVMs) using SMB.

If you configure BranchCache, Windows BranchCache clients first retrieve content from the SVM and then cache the content on a computer within the branch office. If another BranchCache-enabled client in the branch office requests the same content, the SVM first authenticates and authorizes the requesting user. The SVM then determines whether the cached content is still up-to-date and, if it is, sends the client metadata about the cached content. The client then uses the metadata to retrieve content directly from the locally based cache.

[Using offline files to allow caching of files for offline use](#)

= Requirements and guidelines

= BranchCache version support

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

You should be aware of which BranchCache versions ONTAP supports.

ONTAP supports BranchCache 1 and the enhanced BranchCache 2:

- When you configure BranchCache on the SMB server for the storage virtual machine (SVM), you can enable BranchCache 1, BranchCache 2, or all versions.

By default, all versions are enabled.

- If you enable only BranchCache 2, the remote office Windows client machines must support BranchCache 2.

Only SMB 3.0 or later clients support BranchCache 2.

For more information about BranchCache versions, see the Microsoft TechNet Library.

Related information

[Microsoft TechNet Library: technet.microsoft.com/en-us/library/](https://technet.microsoft.com/en-us/library/)

= Network protocol support requirements

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

You must be aware of the network protocol requirements for implementing ONTAP BranchCache.

You can implement the ONTAP BranchCache feature over IPv4 and IPv6 networks using SMB 2.1 or later.

All CIFS servers and branch office machines participating in the BranchCache implementation must have the SMB 2.1 or later protocol enabled. SMB 2.1 has protocol extensions that allow a client to participate in a BranchCache environment. This is the minimum SMB protocol version that offers BranchCache support. SMB 2.1 supports version BranchCache version 1.

If you want to use BranchCache version 2, SMB 3.0 is the minimum supported version. All CIFS servers and branch office machines participating in a BranchCache 2 implementation must have SMB 3.0 or later enabled.

If you have remote offices where some of the clients support only SMB 2.1 and some of the clients support SMB 3.0, you can implement a BranchCache configuration on the CIFS server that provides caching support over both BranchCache 1 and BranchCache 2.

Even though the Microsoft BranchCache feature supports using both the HTTP/HTTPS and SMB protocols as file access protocols, ONTAP BranchCache only supports the use of SMB.

= ONTAP and Windows hosts version requirements

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

ONTAP and branch office Windows hosts must meet certain version requirements before you can configure BranchCache.

Before configuring BranchCache, you must ensure that the version of ONTAP on the cluster and participating branch office clients support SMB 2.1 or later and support the BranchCache feature. If you configure Hosted Cache mode, you must also ensure that you use a supported host for the cache server.

BranchCache 1 is supported on the following ONTAP versions and Windows hosts:

- Content server: storage virtual machine (SVM) with ONTAP
- Cache server: Windows Server 2008 R2 or Windows Server 2012 or later
- Peer or client: Windows 7 Enterprise, Windows 7 Ultimate, Windows 8, Windows Server 2008 R2 or

Windows Server 2012 or later

BranchCache 2 is supported on the following ONTAP versions and Windows hosts:

- Content server: SVM with ONTAP
- Cache server: Windows Server 2012 or later
- Peer or client: Windows 8 or Windows Server 2012 or later

For the latest information about which Windows clients support BranchCache, see the Interoperability Matrix.

mysupport.netapp.com/matrix

= Reasons ONTAP invalidates BranchCache hashes

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Understanding the reasons why ONTAP invalidates hashes can be helpful as you plan your BranchCache configuration. It can help you decide which operating mode you should configure and can help you choose on which shares to enable BranchCache.

ONTAP must manage BranchCache hashes to ensure that hashes are valid. If a hash is not valid, ONTAP invalidates the hash and computes a new hash the next time that content is requested, assuming that BranchCache is still enabled.

ONTAP invalidates hashes for the following reasons:

- The server key is modified.

If the server key is modified, ONTAP invalidates all hashes in the hash store.

- A hash is flushed from the cache because the BranchCache hash store maximum size has been reached.

This is a tunable parameter and can be modified to meet your business requirements.

- A file is modified either through SMB or NFS access.
- A file for which there are computed hashes is restored using the `snap restore` command.
- A volume that contains SMB shares that are BranchCache-enabled is restored using the `snap restore` command.

= Guidelines for choosing the hash store location

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

When configuring BranchCache, you choose where to store hashes and what size the hash store should be. Understanding the guidelines when choosing the hash store location and size can help you plan your BranchCache configuration on a CIFS-

enabled SVM.

- You should locate the hash store on a volume where atime updates are permitted.

The access time on a hash file is used to keep frequently accessed files in the hash store. If atime updates are disabled, the creation time is used for this purpose. It is preferable to use atime to track frequently used files.

- You cannot store hashes on read-only file systems such as SnapMirror destinations and SnapLock volumes.
- If the maximum size of the hash store is reached, older hashes are flushed to make room for new hashes.

You can increase the maximum size of the hash store to reduce the amount of hashes that are flushed from the cache.

- If the volume on which you store hashes is unavailable or full, or if there is an issue with intra-cluster communication where the BranchCache service cannot retrieve hash information, BranchCache services are not available.

The volume might be unavailable because it is offline or because the storage administrator specified a new location for the hash store.

This does not cause issues with file access. If access to the hash store is impeded, ONTAP returns a Microsoft-defined error to the client, which causes the client to request the file using the normal SMB read request.

[Managing and monitoring the BranchCache configuration](#)

= BranchCache recommendations

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

Before you configure BranchCache, there are certain recommendations you should keep in mind when deciding on which SMB shares you want to enable BranchCache caching.

You should keep the following recommendations in mind when deciding on which operating mode to use and on which SMB shares to enable BranchCache:

- The benefits of BranchCache are reduced when the data to be remotely cached changes frequently.
- BranchCache services are beneficial for shares containing file content that is reused by multiple remote office clients or by file content that is repeatedly accessed by a single remote user.
- Consider enabling caching for read-only content such as data in Snapshot copies and SnapMirror destinations.

= Configure BranchCache

= Configure BranchCache overview
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You configure BranchCache on your SMB server using ONTAP commands. To implement BranchCache, you must also configure your clients, and optionally your hosted cache servers at the branch offices where you want to cache content.

If you configure BranchCache to enable caching on a share-by-share basis, you must enable BranchCache on the SMB shares for which you want to provide BranchCache caching services.

= Requirements for configuring BranchCache
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

After meeting some prerequisites, you can set up BranchCache.

The following requirements must be met before configuring BranchCache on the CIFS server for your SVM:

- ONTAP must be installed on all nodes in the cluster.
- CIFS must be licensed and a CIFS server must be configured.
- IPv4 or IPv6 network connectivity must be configured.
- For BranchCache 1, SMB 2.1 or later must be enabled.
- For BranchCache 2, SMB 3.0 must be enabled and the remote Windows clients must support BranchCache 2.

= Configure BranchCache on the SMB server
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can configure BranchCache to provide BranchCache services on a per-share basis. Alternatively, you can configure BranchCache to automatically enable caching on all SMB shares.

About this task

You can configure BranchCache on SVMs.

- You can create an all-shares BranchCache configuration if want to offer caching services for all content contained within all SMB shares on the CIFS server.
- You can create a per-share BranchCache configuration if you want to offer caching services for content contained within selected SMB shares on the CIFS server.

You must specify the following parameters when configuring BranchCache:

Required parameters	Description
<i>SVM name</i>	BranchCache is configured on a per SVM basis. You must specify on which CIFS-enabled SVM you want to configure the BranchCache service.
<i>Path to hash store</i>	<p>BranchCache hashes are stored in regular files on the SVM volume. You must specify the path to an existing directory where you want ONTAP to store the hash data. The BranchCache hash path must be read-writable. Read-only paths, such as Snapshot directories are not allowed. You can store hash data in a volume that contains other data or you can create a separate volume to store hash data.</p> <p>If the SVM is an SVM disaster recovery source, the hash path cannot be on the root volume. This is because the root volume is not replicated to the disaster recovery destination.</p> <p>The hash path can contain blanks and any valid file name characters.</p>

You can optionally specify the following parameters:

Optional parameters	Description
<i>Supported Versions</i>	ONTAP support BranchCache 1 and 2. You can enable version 1, version 2, or both versions. The default is to enable both versions.
<i>Maximum size of hash store</i>	You can specify the size to use for the hash data store. If the hash data exceeds this value, ONTAP deletes older hashes to make room for newer hashes. The default size for the hash store is 1 GB. BranchCache performs more efficiently if hashes are not discarded in an overly aggressive manner. If you determine that hashes are discarded frequently because the hash store is full, you can increase the hash store size by modifying the BranchCache configuration.

Optional parameters	Description
<i>Server key</i>	You can specify a server key that the BranchCache service uses to prevent clients from impersonating the BranchCache server. If you do not specify a server key, one is randomly generated when you create the BranchCache configuration. You can set the server key to a specific value so that if multiple servers are providing BranchCache data for the same files, clients can use hashes from any server using that same server key. If the server key contains any spaces, you must enclose the server key in quotation marks.
<i>Operating mode</i>	<p>The default is to enable BranchCache on a per-share basis.</p> <ul style="list-style-type: none"> • To create a BranchCache configuration where you enable BranchCache on a per-share basis, you can either not specify this optional parameter or you can specify <code>per-share</code>. • To automatically enable BranchCache on all shares, you must set the operating mode to <code>all-shares</code>.

Steps

1. Enable SMB 2.1 and 3.0 as needed:

- Set the privilege level to advanced: `set -privilege advanced`
- Check the configured SVM SMB settings to determine whether all needed versions of SMB are enabled: `vserver cifs options show -vserver vserver_name`
- If necessary, enable SMB 2.1: `vserver cifs options modify -vserver vserver_name -smb2-enabled true`

The command enables both SMB 2.0 and SMB 2.1.

- If necessary, enable SMB 3.0: `vserver cifs options modify -vserver vserver_name -smb3-enabled true`
 - Return to the admin privilege level: `set -privilege admin`
2. Configure BranchCache: `vserver cifs branchcache create -vserver vserver_name -hash-store-path path [-hash-store-max-size {integer[KB|MB|GB|TB|PB]}] [-versions {v1-enable|v2-enable|enable-all}] [-server-key text] -operating-mode {per-share|all-shares}`

The specified hash storage path must exist and must reside on a volume managed by the SVM. The path must also be located on a read-writable volume. The command fails if the path is read-only or does not exist.

If you want to use the same server key for additional SVM BranchCache configurations, record the value you enter for the server key. The server key does not appear when you display information

about the BranchCache configuration.

3. Verify that the BranchCache configuration is correct: vserver cifs branchcache show -vserver vserver_name

Examples

The following commands verify that both SMB 2.1 and 3.0 are enabled and configure BranchCache to automatically enable caching on all SMB shares on SVM vs1:

```
cluster1::> set -privilege advanced
Warning: These advanced commands are potentially dangerous; use them
only when directed to do so by technical support personnel.
Do you wish to continue? (y or n): y

cluster1::*> vserver cifs options show -vserver vs1 -fields smb2-
enabled,smb3-enabled
vserver smb2-enabled smb3-enabled
-----
vs1      true          true

cluster1::*> set -privilege admin

cluster1::*> vserver cifs branchcache create -vserver vs1 -hash-store
-path /hash_data -hash-store-max-size 20GB -versions enable-all -server
-key "my server key" -operating-mode all-shares

cluster1::*> vserver cifs branchcache show -vserver vs1

                      Vserver: vs1
Supported BranchCache Versions: enable_all
Path to Hash Store: /hash_data
Maximum Size of the Hash Store: 20GB
Encryption Key Used to Secure the Hashes: -
CIFS BranchCache Operating Modes: all_shares
```

The following commands verify that both SMB 2.1 and 3.0 are enabled, configure BranchCache to enable caching on a per-share basis on SVM vs1, and verify the BranchCache configuration:

```

cluster1::> set -privilege advanced
Warning: These advanced commands are potentially dangerous; use them
only when directed to do so by technical support personnel.

After configuring BranchCache on the SMB server, you must install and configure BranchCache on client computers and, optionally, on caching servers at your remote

office. Microsoft provides instructions for configuring BranchCache at the remote office.

Instructions for configuring branch office clients and, optionally, caching servers to use BranchCache are on the Microsoft BranchCache web site.

[Microsoft BranchCache: technet.microsoft.com/EN-US/NETWORK/DD425028](https://technet.microsoft.com/EN-US/NETWORK/DD425028)

= Configure BranchCache-enabled SMB shares

= Configure BranchCache-enabled SMB shares overview

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

After you configure BranchCache on the SMB server and at the branch office, you can enable BranchCache on SMB shares that contain content that you want to allow clients at branch offices to cache.

BranchCache caching can be enabled on all SMB shares on the SMB server or on a share-by-share basis.

- If you enable BranchCache on a share-by-share basis, you can enable BranchCache as you create the share or by modifying existing shares.

If you enable caching on an existing SMB share, ONTAP begins computing hashes and sending metadata to clients requesting content as soon as you enable BranchCache on that share.

- Any clients that have an existing SMB connection to a share do not get BranchCache support if BranchCache is subsequently enabled on that share.

ONTAP advertises BranchCache support for a share at the time the SMB session is set up. Clients that already have established sessions when BranchCache is enabled need to disconnect and reconnect to use cached content for this share.

If BranchCache on a SMB share is subsequently disabled, ONTAP stops sending metadata to the requesting client. A client that needs data retrieves it directly from the content server (SMB server).

= Create a BranchCache-enabled SMB share

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can enable BranchCache on an SMB share when you create the share by setting the `branchcache` share property.

About this task

- If BranchCache is enabled on the SMB share, the share must have the offline files configuration set to manual caching.

This is the default setting when you create a share.

- You can also specify additional optional share parameters when you create the BranchCache-enabled share.
- You can set the `branchcache` property on a share even if BranchCache is not configured and enabled on the storage virtual machine (SVM).

However, if you want the share to offer cached content, you must configure and enable BranchCache on the SVM.

- Since there are no default share properties applied to the share when you use the `-share-properties` parameter, you must specify all other share properties that you want applied to the share in addition to the `branchcache` share property by using a comma-delimited list.
- For more information, see the man page for the `vserver cifs share create` command.

Step

1. Create a BranchCache-enabled SMB share:

```
vserver cifs share create -vserver vserver_name -share-name share_name
-path path -share-properties branchcache[,...]
```

2. Verify that the BranchCache share property is set on the SMB share by using the `vserver cifs share show` command.

Example

The following command creates a BranchCache-enabled SMB share named “data” with a path of `/data` on SVM vs1. By default, the offline files setting is set to `manual`:

```
cluster1::> vserver cifs share create -vserver vs1 -share-name data
-path /data -share-properties
branchcache,oplocks,browsable,changetrigger

cluster1::> vserver cifs share show -vserver vs1 -share-name data
          Vserver: vs1
          Share: data
          CIFS Server NetBIOS Name: VS1
          Path: /data
          Share Properties: branchcache
                           oplocks
                           browsable
                           changetrigger
          Symlink Properties: enable
          File Mode Creation Mask: -
          Directory Mode Creation Mask: -
          Share Comment: -
          Share ACL: Everyone / Full Control
          File Attribute Cache Lifetime: -
                           Volume Name: data
                           Offline Files: manual
          Vsnap File-Operations Profile: standard
```

Related information

[Disabling BranchCache on a single SMB share](#)

= Enable BranchCache on an existing SMB share

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can enable BranchCache on an existing SMB share by adding the `branchcache` share property to the existing list of share properties.

About this task

- If BranchCache is enabled on the SMB share, the share must have the offline files configuration set to manual caching.

If the existing share's offline files setting is not set to manual caching, you must configure it by modifying the share.

- You can set the `branchcache` property on a share even if BranchCache is not configured and enabled on the storage virtual machine (SVM).

However, if you want the share to offer cached content, you must configure and enable BranchCache on the SVM.

- When you add the `branchcache` share property to the share, existing share settings and share properties are preserved.

The BranchCache share property is added to the existing list of share properties. For more information about using the `vserver cifs share properties add` command, see the man pages.

Steps

1. If necessary, configure the offline files share setting for manual caching:
 - a. Determine what the offline files share setting is by using the `vserver cifs share show` command.
 - b. If the offline files share setting is not set to manual, change it to the required value: `vserver cifs share modify -vserver vserver_name -share-name share_name -offline -files manual`
2. Enable BranchCache on an existing SMB share: `vserver cifs share properties add -vserver vserver_name -share-name share_name -share-properties branchcache`
3. Verify that the BranchCache share property is set on the SMB share: `vserver cifs share show -vserver vserver_name -share-name share_name`

Example

The following command enables BranchCache on an existing SMB share named "data2" with a path of /data2 on SVM vs1:

```
cluster1::> vserver cifs share show -vserver vs1 -share-name data2
```

```
          Vserver: vs1
          Share: data2
CIFS Server NetBIOS Name: VS1
          Path: /data2
Share Properties: oplocks
                  browsable
                  changenotify
                  showsnapshot
Symlink Properties: -
File Mode Creation Mask: -
Directory Mode Creation Mask: -
Share Comment: -
Share ACL: Everyone / Full Control
File Attribute Cache Lifetime: 10s
          Volume Name: -
Offline Files: manual
Vscan File-Operations Profile: standard
```

```
cluster1::> vserver cifs share properties add -vserver vs1 -share-name
data2 -share-properties branchcache
```

```
cluster1::> vserver cifs share show -vserver vs1 -share-name data2
```

```
          Vserver: vs1
          Share: data2
CIFS Server NetBIOS Name: VS1
          Path: /data2
Share Properties: oplocks
                  browsable
                  showsnapshot
                  changenotify
                  branchcache
Symlink Properties: -
File Mode Creation Mask: -
Directory Mode Creation Mask: -
Share Comment: -
Share ACL: Everyone / Full Control
File Attribute Cache Lifetime: 10s
          Volume Name: -
Offline Files: manual
Vscan File-Operations Profile: standard
```

[Disabling BranchCache on a single SMB share](#)

= Manage and monitor the BranchCache configuration

= Modify BranchCache configurations

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can modify the configuration of the BranchCache service on SVMs, including changing the hash store directory path, the hash store maximum directory size, the operating mode, and which BranchCache versions are supported. You can also increase the size of the volume that contains the hash store.

Steps

1. Perform the appropriate action:

If you want to...	Enter the following...
Modify the hash store directory size	<pre>vserver cifs branchcache modify -vserver vserver_name -hash-store -max-size {integer[KB MB GB TB PB]}</pre>
Increase the size of the volume that contains the hash store	<pre>volume size -vserver vserver_name -volume volume_name -new-size new_size[k m g t]</pre> <p>If the volume containing the hash store fills up, you might be able to increase the size of the volume. You can specify the new volume size as a number followed by a unit designation.</p> <p>See Logical storage management for more information about increasing volume size.</p>

If you want to...	Enter the following...
Modify the hash store directory path	<pre>vserver cifs branchcache modify -vserver vserver_name -hash-store -path path -flush-hashes {true false}</pre> <p>If the SVM is an SVM disaster recovery source, the hash path cannot be on the root volume. This is because the root volume is not replicated to the disaster recovery destination.</p> <p>The BranchCache hash path can contain blanks and any valid file name characters.</p> <p>If you modify the hash path, <code>-flush-hashes</code> is a required parameter that specifies whether you want ONTAP to flush the hashes from the original hash store location. You can set the following values for the <code>-flush-hashes</code> parameter:</p> <ul style="list-style-type: none"> • If you specify <code>true</code>, ONTAP deletes the hashes in the original location and creates new hashes in the new location as new requests are made by BranchCache-enabled clients. • If you specify <code>false</code>, the hashes are not flushed. <p>In this case, you can choose to reuse the existing hashes later by changing the hash store path back to the original location.</p>
Change the operating mode	<pre>vserver cifs branchcache modify -vserver vserver_name -operating -mode {per-share all-shares disable}</pre> <p> You should be aware of the following when modifying the operating mode:</p> <ul style="list-style-type: none"> - ONTAP advertises BranchCache support for a share when the SMB session is set up. - Clients that already have established sessions when BranchCache is enabled need to disconnect and reconnect to use cached content for this share.

If you want to...	Enter the following...
Change the BranchCache version support	vserver cifs branchcache modify -vserver vserver_name -versions {v1-enable v2-enable enable-all}

2. Verify the configuration changes by using the `vserver cifs branchcache show` command.

[Logical Storage Management Guide](#)

= Display information about BranchCache configurations

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can display information about BranchCache configurations on storage virtual machines (SVMs), which can be used when verifying a configuration or when determining current settings before modifying a configuration.

Step

1. Perform one of the following actions:

If you want to display...	Enter this command...
Summary information about BranchCache configurations on all SVMs	<code>vserver cifs branchcache show</code>
Detailed information about the configuration on a specific SVM	<code>vserver cifs branchcache show -vserver vserver_name</code>

Example

The following example displays information about the BranchCache configuration on SVM vs1:

```
cluster1::> vserver cifs branchcache show -vserver vs1

Vserver: vs1
Supported BranchCache Versions: enable_all
Path to Hash Store: /hash_data
Maximum Size of the Hash Store: 20GB
Encryption Key Used to Secure the Hashes: -
CIFS BranchCache Operating Modes: per_share
```

= Change the BranchCache server key

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can change the BranchCache server key by modifying the BranchCache configuration on the storage virtual machine (SVM) and specifying a different server key.

About this task

You can set the server key to a specific value so that if multiple servers are providing BranchCache data for the same files, clients can use hashes from any server using that same server key.

When you change the server key, you must also flush the hash cache. After flushing the hashes, ONTAP creates new hashes as new requests are made by BranchCache-enabled clients.

Steps

1. Change the server key by using the following command:
`vserver cifs branchcache modify -vserver vserver_name -server-key text -flush-hashes true`
When configuring a new server key, you must also specify `-flush-hashes` and set the value to true.
2. Verify that the BranchCache configuration is correct by using the `vserver cifs branchcache show` command.

Example

The following example sets a new server key that contains spaces and flushes the hash cache on SVM vs1:

```
cluster1::> vserver cifs branchcache modify -vserver vs1 -server-key  
"new vserver secret" -flush-hashes true  
  
cluster1::> vserver cifs branchcache show -vserver vs1  
  
          Vserver: vs1  
Supported BranchCache Versions: enable_all  
          Path to Hash Store: /hash_data  
          Maximum Size of the Hash Store: 20GB  
Encryption Key Used to Secure the Hashes: -  
          CIFS BranchCache Operating Modes: per_share
```

Related information

[Reasons ONTAP invalidates BranchCache hashes](#)

= Pre-compute BranchCache hashes on specified paths
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can configure the BranchCache service to pre-compute hashes for a single file, for a directory, or for all files in a directory structure. This can be helpful if you want to compute hashes on data in a BranchCache-enabled share during off, non-peak

hours.

About this task

If you want to collect a data sample before you display hash statistics, you must use the `statistics start` and optional `statistics stop` commands.

- You must specify the storage virtual machine (SVM) and path on which you want to pre-compute hashes.
- You must also specify whether you want hashes computed recursively.
- If you want hashes computed recursively, the BranchCache service traverses the entire directory tree under the specified path, and computes hashes for each eligible object.

Steps

1. Pre-compute hashes as desired:

If you want to pre-compute hashes on...	Enter the command...
A single file or directory	<code>vserver cifs branchcache hash-create -vserver vserver_name -path path -recurse false</code>
Recursively on all files in a directory structure	<code>vserver cifs branchcache hash-create -vserver vserver_name -path absolute_path -recurse true</code>

2. Verify that hashes are being computed by using the `statistics` command:

- a. Display statistics for the `hashd` object on the desired SVM instance: `statistics show -object hashd -instance vserver_name`
- b. Verify that the number of hashes created is increasing by repeating the command.

Examples

The following example creates hashes on the path `/data` and on all contained files and subdirectories on SVM `vs1`:

```
cluster1::> vserver cifs branchcache hash-create -vserver vs1 -path /data -recurse true
```

```
cluster1::> statistics show -object hashd -instance vs1
Object: hashd
Instance: vs1
Start-time: 9/6/2012 19:09:54
End-time: 9/6/2012 19:11:15
Cluster: cluster1
```

Counter	Value
branchcache_hash_created	85
branchcache_hash_files_replaced	0
branchcache_hash_rejected	0
branchcache_hash_store_bytes	0
branchcache_hash_store_size	0
instance_name	vs1
node_name	node1
node_uuid	11111111-1111-1111-1111-111111111111
process_name	-

```
cluster1::> statistics show -object hashd -instance vs1
Object: hashd
Instance: vs1
Start-time: 9/6/2012 19:09:54
End-time: 9/6/2012 19:11:15
Cluster: cluster1
```

Counter	Value
branchcache_hash_created	92
branchcache_hash_files_replaced	0
branchcache_hash_rejected	0
branchcache_hash_store_bytes	0
branchcache_hash_store_size	0
instance_name	vs1
node_name	node1
node_uuid	11111111-1111-1111-1111-111111111111
process_name	-

Related information

[Performance monitoring setup](#)

= Flush hashes from the SVM BranchCache hash store
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can flush all cached hashes from the BranchCache hash store on the storage virtual machine (SVM). This can be useful if you have changed the branch office BranchCache configuration. For example, if you recently reconfigured the caching mode from distributed caching to hosted caching mode, you would want to flush the hash store.

About this task

After flushing the hashes, ONTAP creates new hashes as new requests are made by BranchCache-enabled clients.

Step

1. Flush the hashes from the BranchCache hash store: `vserver cifs branchcache hash-flush -vserver vserver_name`

```
vserver cifs branchcache hash-flush -vserver vs1
```

= Display BranchCache statistics

:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can display BranchCache statistics to, among other things, identify how well caching is performing, determine whether your configuration is providing cached content to clients, and determine whether hash files were deleted to make room for more recent hash data.

About this task

The `hashd` statistic object contains counters that provide statistical information about BranchCache hashes. The `cifs` statistic object contains counters that provide statistical information about BranchCache-related activity. You can collect and display information about these objects at the advanced-privilege level.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`

```
cluster1::> set -privilege advanced
```

Warning: These advanced commands are potentially dangerous; use them only when directed to do so by support personnel.

Do you want to continue? {y|n}: y

2. Display the BranchCache-related counters by using the `statistics catalog counter show` command.

For more information about statistics counters, see the man page for this command.

```
cluster1::*> statistics catalog counter show -object hashd

Object: hashd
      Counter          Description
      -----
      -----
      branchcache_hash_created    Number of times a request to
generate
                                         BranchCache hash for a file
succeeded.

      branchcache_hash_files_replaced
                                         Number of times a BranchCache hash
file was
                                         deleted to make room for more recent
hash
                                         data. This happens if the hash store
size is
                                         exceeded.

      branchcache_hash_rejected    Number of times a request to
generate
                                         BranchCache hash failed.

      branchcache_hash_store_bytes
                                         Total number of bytes used to store
hash data.

      branchcache_hash_store_size Total space used to store
BranchCache hash
                                         data for the Vserver.

      instance_name               Instance Name
      instance_uuid               Instance UUID
      node_name                   System node name
      node_uuid                   System node id

9 entries were displayed.
```

```
cluster1::*> statistics catalog counter show -object cifs
```

```
Object: cifs
      Counter          Description
      -----
      -----
      active_searches      Number of active searches over SMB
and SMB2
      auth_reject_too_many Authentication refused after too
many
                                         requests were made in rapid
```

```

succession
    avg_directory_depth           Average number of directories
    crossed by SMB
    avg_junction_depth           and SMB2 path-based commands
    by SMB                         Average number of junctions crossed
                                    and SMB2 path-based commands
    branchcache_hash_fetch_fail   Total number of times a request to
    fetch hash                     data failed. These are failures when
                                    attempting to read existing hash
data. It
                                    does not include attempts to fetch
hash data
                                    that has not yet been generated.
branchcache_hash_fetch_ok     Total number of times a request to
fetch hash                     data succeeded.
branchcache_hash_sent_bytes   Total number of bytes sent to
clients
                                    requesting hashes.
branchcache_missing_hash_bytes
                                    Total number of bytes of data that
had to be
                                    read by the client because the hash
for that
                                    content was not available on the
server.
....Output truncated....

```

3. Collect BranchCache-related statistics by using the `statistics start` and `statistics stop` commands.

```

cluster1::>*> statistics start -object cifs -vserver vs1 -sample-id
11
Statistics collection is being started for Sample-id: 11

cluster1::>*> statistics stop -sample-id 11
Statistics collection is being stopped for Sample-id: 11

```

4. Display the collected BranchCache statistics by using the `statistics show` command.

```
cluster1::*> statistics show -object cifs -counter  
branchcache_hash_sent_bytes -sample-id 11
```

Object: cifs
Instance: vs1
Start-time: 12/26/2012 19:50:24
End-time: 12/26/2012 19:51:01
Cluster: cluster1

Counter	Value
branchcache_hash_sent_bytes	0

```
cluster1::*> statistics show -object cifs -counter  
branchcache_missing_hash_bytes -sample-id 11
```

Object: cifs
Instance: vs1

= Support for BranchCache Group Policy Objects

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ONTAP BranchCache provides support for BranchCache Group Policy Objects (GPOs), which allow centralized management for certain BranchCache configuration parameters. There are two GPOs used for BranchCache, the Hash Publication for BranchCache GPO and the Hash Version Support for BranchCache GPO.

- **Hash Publication for BranchCache GPO**

The Hash Publication for BranchCache GPO corresponds to the `-operating-mode` parameter. When GPO updates occur, this value is applied to storage virtual machine (SVM) objects contained within the organizational unit (OU) to which the group policy applies.

- **Hash Version Support for BranchCache GPO**

The Hash Version Support for BranchCache GPO corresponds to the `-versions` parameter. When GPO updates occur, this value is applied to SVM objects contained within the organizational unit to which the group policy applies.

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can display information about the CIFS server's Group Policy Object (GPO) configuration to determine whether BranchCache GPOs are defined for the domain to which the CIFS server belongs and, if so, what the allowed settings are. You can also determine whether BranchCache GPO settings are applied to the CIFS server.

About this task

Even though a GPO setting is defined within the domain to which the CIFS server belongs, it is not necessarily applied to the organizational unit (OU) containing the CIFS-enabled storage virtual machine (SVM). Applied GPO setting are the subset of all defined GPOs that are applied to the CIFS-enabled SVM. BranchCache settings applied through GPOs override settings applied through the CLI.

Steps

1. Display the defined BranchCache GPO setting for the Active Directory domain by using the vserver cifs group-policy show-defined command.

This example does not display all of the available output fields for the command.
Output is truncated.

```
cluster1::> vserver cifs group-policy show-defined -vserver vs1

Vserver: vs1
-----
      GPO Name: Default Domain Policy
      Level: Domain
      Status: enabled
Advanced Audit Settings:
  Object Access:
    Central Access Policy Staging: failure
Registry Settings:
  Refresh Time Interval: 22
  Refresh Random Offset: 8
  Hash Publication Mode for BranchCache: per-share
  Hash Version Support for BranchCache: version1
[...]

      GPO Name: Resultant Set of Policy
      Status: enabled
Advanced Audit Settings:
  Object Access:
    Central Access Policy Staging: failure
Registry Settings:
  Refresh Time Interval: 22
  Refresh Random Offset: 8
  Hash Publication for Mode BranchCache: per-share
  Hash Version Support for BranchCache: version1
[...]
```

2. Display the BranchCache GPO setting applied to the CIFS server by using the vserver cifs group-policy show-applied command.``

This example does not display all of the available output fields for the command.
Output is truncated.

```
cluster1::> vserver cifs group-policy show-applied -vserver vs1

Vserver: vs1
-----
    GPO Name: Default Domain Policy
        Level: Domain
        Status: enabled
    Advanced Audit Settings:
        Object Access:
            Central Access Policy Staging: failure
    Registry Settings:
        Refresh Time Interval: 22
        Refresh Random Offset: 8

= Disable BranchCache on SMB shares

= Disable BranchCache on SMB shares overview

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you do not want to provide BranchCache caching services on certain SMB shares but you might want to provide caching services on those shares later, you can disable BranchCache on a share-by-share basis. If you have BranchCache configured to offer caching on all shares but you want to temporarily disable all caching services, you can modify the BranchCache configuration to stop automatic caching on all shares.

If BranchCache on an SMB share is subsequently disabled after first being enabled, ONTAP stops sending metadata to the requesting client. A client that needs data retrieves it directly from the content server (CIFS server on the storage virtual machine (SVM)).

Related information

[Configuring BranchCache-enabled SMB shares](#)

= Disable BranchCache on a single SMB share

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

If you do not want to offer caching services on certain shares that previously offered cached content, you can disable BranchCache on an existing SMB share.

Step

1. Enter the following command:
vserver cifs share properties remove -vserver
vserver_name -share-name share_name -share-properties branchcache

The BranchCache share property is removed. Other applied share properties remain in effect.

Example

The following command disables BranchCache on an existing SMB share named “data2”:

```
cluster1::> vserver cifs share show -vserver vs1 -share-name data2
```

```
        Vserver: vs1
        Share: data2
CIFS Server NetBIOS Name: VS1
        Path: /data2
Share Properties: oplocks
                browsable
                changenotify
                attributecache
                branchcache
Symlink Properties: -
File Mode Creation Mask: -
Directory Mode Creation Mask: -
Share Comment: -
Share ACL: Everyone / Full Control
File Attribute Cache Lifetime: 10s
        Volume Name: -
Offline Files: manual
Vscan File-Operations Profile: standard
```

```
cluster1::> vserver cifs share properties remove -vserver vs1 -share
-name data2 -share-properties branchcache
```

```
cluster1::> vserver cifs share show -vserver vs1 -share-name data2
```

```
        Vserver: vs1
        Share: data2
CIFS Server NetBIOS Name: VS1
        Path: /data2
Share Properties: oplocks
                browsable
                changenotify
                attributecache

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

If your BranchCache configuration automatically enables caching on all SMB shares on each storage virtual machine (SVM), you can modify the BranchCache configuration to stop automatically caching content for all SMB shares.

About this task

To stop automatic caching on all SMB shares, you change the BranchCache operating mode to per-share caching.

Steps

1. Configure BranchCache to stop automatic caching on all SMB shares: `vserver cifs branchcache modify -vserver vserver_name -operating-mode per-share`
2. Verify that the BranchCache configuration is correct: `vserver cifs branchcache show -vserver vserver_name`

Example

The following command changes the BranchCache configuration on storage virtual machine (SVM, formerly known as Vserver) vs1 to stop automatic caching on all SMB shares:

```
cluster1::> vserver cifs branchcache modify -vserver vs1 -operating
-mode per-share

cluster1::> vserver cifs branchcache show -vserver vs1

          Vserver: vs1
Supported BranchCache Versions: enable_all
          Path to Hash Store: /hash_data
          Maximum Size of the Hash Store: 20GB
Encryption Key Used to Secure the Hashes: -
          CIFS BranchCache Operating Modes: per_share
```

= Disable or enable BranchCache on the SVM

= What happens when you disable or reenable BranchCache on the CIFS server

```
:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

If you previously configured BranchCache but do not want the branch office clients to use cached content, you can disable caching on the CIFS server. You must be aware of what happens when you disable BranchCache.

When you disable BranchCache, ONTAP no longer computes hashes or sends the metadata to the requesting client. However, there is no interruption to file access. Thereafter, when BranchCache-enabled clients request metadata information for content they want to access, ONTAP responds with a Microsoft-

defined error, which causes the client to send a second request, requesting the actual content. In response to the request for content, the CIFS server sends the actual content that is stored on the storage virtual machine (SVM).

After BranchCache is disabled on the CIFS server, SMB shares do not advertise BranchCache capabilities. To access data on new SMB connections, clients make normal read SMB requests.

You can reenable BranchCache on the CIFS server at any time.

- Because the hash store is not deleted when you disable BranchCache, ONTAP can use the stored hashes when replying to hash requests after you reenable BranchCache, provided that the requested hash is still valid.
- Any clients that have made SMB connections to BranchCache-enabled shares during the time when BranchCache was disabled do not get BranchCache support if BranchCache is subsequently reenabled.

This is because ONTAP advertises BranchCache support for a share at the time the SMB session is set up. Clients that established sessions to BranchCache-enabled shares while BranchCache was disabled need to disconnect and reconnect to use cached content for this share.

If you do not want to save the hash store after you disable BranchCache on a CIFS server, you can manually delete it. If you reenable BranchCache, you must ensure that the hash store directory exists. After BranchCache is reenabled, BranchCache-enabled shares advertise BranchCache capabilities. ONTAP creates new hashes as new requests are made by BranchCache-enabled clients.

= Disable or enable BranchCache

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..../media/

You can disable BranchCache on the storage virtual machine (SVM) by changing the BranchCache operating mode to disabled. You can enable BranchCache at any time by changing the operating mode to either offer BranchCache services per-share or automatically for all shares.

Steps

1. Run the appropriate command:

If you want to...	Then enter the following...
Disable BranchCache	<code>vserver cifs branchcache modify -vserver vserver_name -operating -mode disable</code>
Enable BranchCache per share	<code>vserver cifs branchcache modify -vserver vserver_name -operating -mode per-share</code>

If you want to...	Then enter the following...
Enable BranchCache for all shares	vserver cifs branchcache modify -vserver vserver_name -operating -mode all-shares

2. Verify that the BranchCache operating mode is configured with the desired setting: vserver cifs branchcache show -vserver vserver_name

Example

The following example disables BranchCache on SVM vs1:

```
cluster1::> vserver cifs branchcache modify -vserver vs1 -operating
-mode disable

cluster1::> vserver cifs branchcache show -vserver vs1

          Vserver: vs1
Supported BranchCache Versions: enable_all
          Path to Hash Store: /hash_data
Maximum Size of the Hash Store: 20GB
Encryption Key Used to Secure the Hashes: -
          CIFS BranchCache Operating Modes: disable
```

= Delete the BranchCache configuration on SVMs

= What happens when you delete the BranchCache configuration

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you previously configured BranchCache but do not want the storage virtual machine (SVM) to continue providing cached content, you can delete the BranchCache configuration on the CIFS server. You must be aware of what happens when you delete the configuration.

When you delete the configuration, ONTAP removes the configuration information for that SVM from the cluster and stops the BranchCache service. You can choose whether ONTAP should delete the hash store on the SVM.

Deleting the BranchCache configuration does not disrupt access by BranchCache-enabled clients. Thereafter, when BranchCache-enabled clients request metadata information on existing SMB connections for content that is already cached, ONTAP responds with a Microsoft defined error, which causes the client to send a second request, requesting the actual content. In response to the request for content, the CIFS server sends the actual content that is stored on the SVM.

After the BranchCache configuration is deleted, SMB shares do not advertise BranchCache capabilities. To access content that has not previously been cached using new SMB connections, clients make normal read SMB requests.

= Delete the BranchCache configuration
 :icons: font
 :relative_path: ./smb-admin/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The command you use for deleting the BranchCache service on your storage virtual machine (SVM) differs depending on whether you want to delete or keep existing hashes.

Step

1. Run the appropriate command:

If you want to...	Then enter the following...
Delete the BranchCache configuration and delete existing hashes	vserver cifs branchcache delete -vserver vserver_name -flush-hashes true
Delete the BranchCache configuration but keep existing hashes	vserver cifs branchcache delete -vserver vserver_name -flush-hashes false

Example

The following example deletes the BranchCache configuration on SVM vs1 and deletes all existing hashes:

```
cluster1::> vserver cifs branchcache delete -vserver vs1 -flush-hashes  
true
```

= What happens to BranchCache when reverting
 :icons: font
 :relative_path: ./smb-admin/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

It is important to understand what happens when you revert ONTAP to a release that does not support BranchCache.

- When you revert to a version of ONTAP that does not support BranchCache, the SMB shares do not advertise BranchCache capabilities to BranchCache-enabled clients; therefore, the clients do not request hash information.

Instead, they request the actual content using normal SMB read requests. In response to the request for content, the SMB server sends the actual content that is stored on the storage virtual machine (SVM).

- When a node hosting a hash store is reverted to a release that does not support BranchCache, the storage administrator needs to manually revert the BranchCache configuration using a command that is printed out during the revert.

This command deletes the BranchCache configuration and hashes.

After the revert completes, the storage administrator can manually delete the directory that contained the hash store if desired.

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Microsoft Offloaded Data Transfer (ODX), also known as *copy offload*, enables direct data transfers within or between compatible storage devices without transferring the data through the host computer.

ONTAP supports ODX for both the SMB and SAN protocols. The source can be either a CIFS server or LUN, and the destination can be either a CIFS server or LUN.

In non-ODX file transfers, the data is read from the source and is transferred across the network to the client computer. The client computer transfers the data back over the network to the destination. In summary, the client computer reads the data from the source and writes it to the destination. With ODX file transfers, data is copied directly from the source to the destination.

Because ODX offloaded copies are performed directly between the source and destination storage, there are significant performance benefits. The performance benefits realized include faster copy time between source and destination, reduced resource utilization (CPU, memory) on the client, and reduced network I/O bandwidth utilization.

For SMB environments, this functionality is only available when both the client and the storage server support SMB 3.0 and the ODX feature. For SAN environments, this functionality is only available when both the client and the storage server support the ODX feature. Client computers that support ODX and have ODX enabled automatically and transparently use offloaded file transfer when moving or copying files. ODX is used irrespective of whether you drag-and-drop files through Windows Explorer or use command-line file copy commands, or whether a client application initiates file copy requests.

= How ODX works

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ODX copy offload uses a token-based mechanism for reading and writing data within or between ODX-enabled CIFS servers. Instead of routing the data through the host, the CIFS server sends a small token, which represents the data, to the client. The ODX client presents that token to the destination server, which then can transfer the

data represented by that token from the source to the destination.

When an ODX client learns that the CIFS server is ODX-capable, it opens the source file and requests a token from the CIFS server. After opening the destination file, the client uses the token to instruct the server to copy the data directly from the source to the destination.

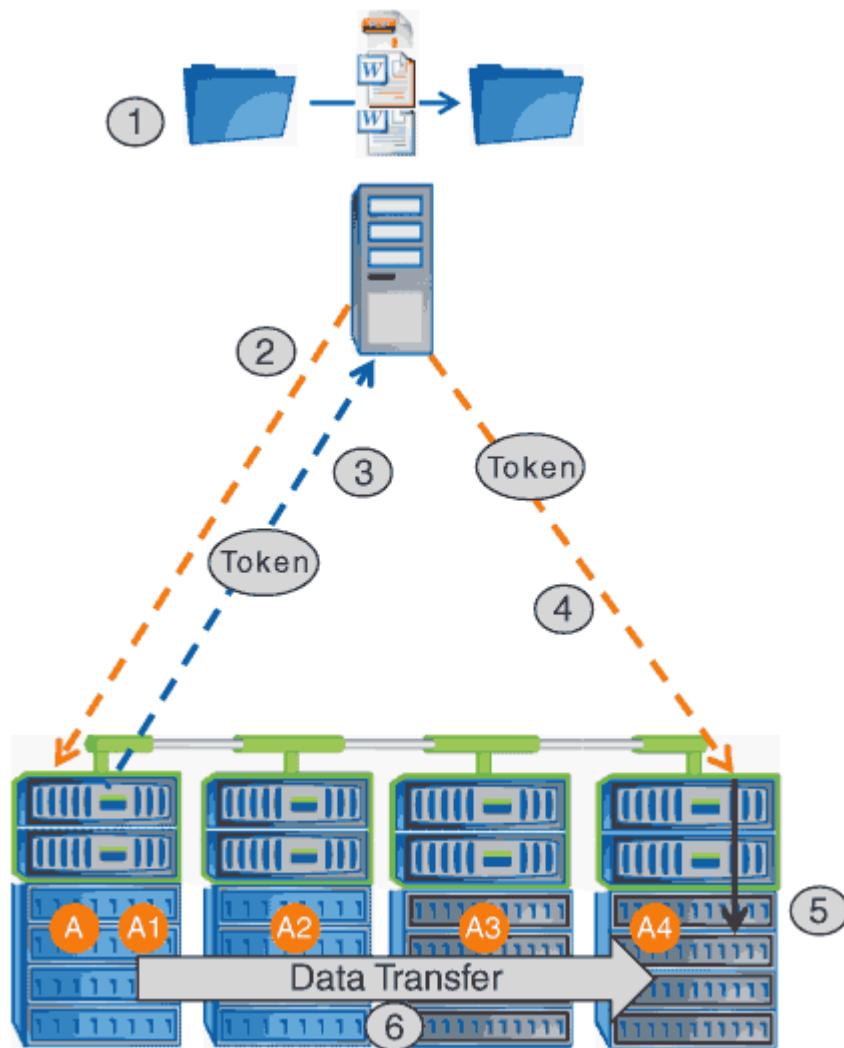

The source and destination can be on the same storage virtual machine (SVM) or on different SVMs, depending on the scope of the copy operation.

The token serves as a point-in-time representation of the data. As an example, when you copy data between storage locations, a token representing a data segment is returned to the requesting client, which the client copies to the destination, thereby removing the need to copy the underlying data through the client.

ONTAP supports tokens that represent 8 MB of data. ODX copies of greater than 8 MB are performed by using multiple tokens, with each token representing 8 MB of data.

The following figure explains the steps that are involved with an ODX copy operation:

1. A user copies or moves a file by using Windows Explorer, a command-line interface, or as part of a virtual machine migration, or an application initiates file copies or moves.
2. The ODX-capable client automatically translates this transfer request into an ODX request.

The ODX request that is sent to the CIFS server contains a request for a token.

3. If ODX is enabled on the CIFS server and the connection is over SMB 3.0, the CIFS server generates a token, which is a logical representation of the data on the source.
4. The client receives a token that represents the data and sends it with the write request to the destination CIFS server.

This is the only data that is copied over the network from the source to the client and then from the client to the destination.

5. The token is delivered to the storage subsystem.
6. The SVM internally performs the copy or move.

If the file that is copied or moved is larger than 8 MB, multiple tokens are needed to perform the copy. Steps 2 through 6 as performed as needed to complete the copy.

If there is a failure with the ODX offloaded copy, the copy or move operation falls back to traditional reads and writes for the copy or move operation. Similarly, if the destination CIFS server does not support ODX or ODX is disabled, the copy or move operation falls back to traditional reads and writes for the copy or move operation.

= Requirements for using ODX

```
:icons: font  
:relative_path: ./smb-admin/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

Before you can use ODX for copy offloads with your storage virtual machine (SVM), you need to be aware of certain requirements.

== ONTAP version requirements

ONTAP releases support ODX for copy offloads.

== SMB version requirements

- ONTAP supports ODX with SMB 3.0 and later.
- SMB 3.0 must be enabled on the CIFS server before ODX can be enabled:
 - Enabling ODX also enables SMB 3.0, if it is not already enabled.
 - Disabling SMB 3.0 also disables ODX.

== Windows server and client requirements

Before you can use ODX for copy offloads, the Windows client must support the feature. Support for ODX starts with Windows 2012 Server and Windows 8.

The Interoperability Matrix contains the latest information about supported Windows clients.

[NetApp Interoperability Matrix Tool](#)

== Volume requirements

- Source volumes must be a minimum of 1.25 GB.
- Deduplication must be enabled on volumes used with copy offload.
- If you use compressed volumes, the compression type must be adaptive and only compression group size 8K is supported.

Secondary compression type is not supported.

= Guidelines for using ODX

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Before you can use ODX for copy offload, you need to be aware of the guidelines. For example, you need to know on which types of volumes you can use ODX and you need to understand the intra-cluster and inter-cluster ODX considerations.

== Volume guidelines

- You cannot use ODX for copy offload with the following volume configurations:
 - Source volume size is less than 1.25 GB
The volume size must be 1.25 GB or larger to use ODX.
 - Read-only volumes
ODX is not used for files and folders residing in load-sharing mirrors or in SnapMirror or SnapVault destination volumes.
 - If the source volume is not deduplicated
- ODX copies are supported only for intra-cluster copies.
You cannot use ODX to copy files or folders to a volume in another cluster.

== Other guidelines

- In SMB environments, to use ODX for copy offload, the files must be 256 kb or larger.
Smaller files are transferred using a traditional copy operation.
- ODX copy offload uses deduplication as part of the copy process.
If you do not want deduplication to occur on SVM volumes when copying or moving data, you should disable ODX copy offload on that SVM.
- The application that performs the data transfer must be written to support ODX.

Application operations that support ODX include the following:

- Hyper-V management operations, such as creating and converting virtual hard disks (VHDs), managing Snapshot copies, and copying files between virtual machines
- Windows Explorer operations

- Windows PowerShell copy commands
- Windows command prompt copy commands

Robocopy at the Windows command prompt supports ODX.

The applications must be running on Windows servers or clients that support ODX.

For more information about supported ODX applications on Windows servers and clients, consult the Microsoft TechNet Library.

Related information

[Microsoft TechNet Library: technet.microsoft.com/en-us/library/](https://technet.microsoft.com/en-us/library/)

= Use cases for ODX

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..../media/

You should be aware of the use cases for using ODX on SVMs so that you can determine under what circumstances ODX provides you with performance benefits.

Windows servers and clients that support ODX use copy offload as the default way of copying data across remote servers. If the Windows server or client does not support ODX or the ODX copy offload fails at any point, the copy or move operation falls back to traditional reads and writes for the copy or move operation.

The following use cases support using ODX copies and moves:

- Intra-volume

The source and destination files or LUNs are within the same volume.

- Inter-volume, same node, same SVM

The source and destination files or LUNs are on different volumes that are located on the same node. The data is owned by the same SVM.

- Inter-volume, different nodes, same SVM

The source and destination files or LUNs are on different volumes that are located on different nodes. The data is owned by the same SVM.

- Inter-SVM, same node

The source and destination file or LUNs are on different volumes that are located on the same node. The data is owned by different SVMs.

- Inter-SVM, different nodes

The source and destination file or LUNs are on different volumes that are located on different nodes. The data is owned by different SVMs.

- Inter-cluster

The source and destination LUNs are on different volumes that are located on different nodes across clusters. This is only supported for SAN and does not work for CIFS.

There are some additional special use cases:

- With the ONTAP ODX implementation, you can use ODX to copy files between SMB shares and FC or iSCSI attached virtual drives.

You can use Windows Explorer, the Windows CLI or PowerShell, Hyper-V, or other applications that support ODX to copy or move files seamlessly using ODX copy offload between SMB shares and connected LUNs, provided that the SMB shares and LUNs are on the same cluster.

- Hyper-V provides some additional use cases for ODX copy offload:

- You can use ODX copy offload pass-through with Hyper-V to copy data within or across virtual hard disk (VHD) files or to copy data between mapped SMB shares and connected iSCSI LUNs within the same cluster.

This allows copies from guest operating systems to pass through to the underlying storage.

- When creating fixed-sized VHDs, ODX is used for initializing the disk with zeros, using a well-known zeroed token.
- ODX copy offload is used for virtual machine storage migration if the source and destination storage is on the same cluster.

To take advantage of the use cases for ODX copy offload pass-through with Hyper-V, the guest operating system must support ODX and the guest operating system's disks must be SCSI disks backed by storage (either SMB or SAN) that supports ODX. IDE disks on the guest operating system do not support ODX pass-through.

= Enable or disable ODX

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..../media/

You can enable or disable ODX on storage virtual machines (SVMs). The default is to enable support for ODX copy offload if SMB 3.0 is also enabled.

Before you begin

SMB 3.0 must be enabled.

About this task

If you disable SMB 3.0, ONTAP also disables SMB ODX. If you reenable SMB 3.0, you must manually reenable SMB ODX.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Perform one of the following actions:

If you want ODX copy offload to be...	Enter the command...
Enabled	vserver cifs options modify -vserver vserver_name -copy-offload-enabled true
Disabled	vserver cifs options modify -vserver vserver_name -copy-offload-enabled false

3. Return to the admin privilege level: set -privilege admin

Example

The following example enables ODX copy offload on SVM vs1:

```
cluster1::> set -privilege advanced
Warning: These advanced commands are potentially dangerous; use them
only when directed to do so by technical support personnel.
Do you wish to continue? (y or n): y

cluster1::*> vserver cifs options modify -vserver vs1 -copy-offload
-enabled true

cluster1::*> set -privilege admin
```

Related information

[Available SMB server options](#)

= Improve client response time by providing SMB automatic node referrals with Auto Location
 :icons: font
 :relative_path: ./smb-admin/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Auto Location uses SMB automatic node referrals to increase SMB client performance on storage virtual machines (SVMs). Automatic node referrals automatically redirect the requesting client to a LIF on the node SVM that is hosting the volume in which the data resides, which can lead to improved client response times.

When an SMB client connects to an SMB share hosted on the SVM, it might connect using a LIF that is on a node that does not own the requested data. The node to which the client is connected accesses data owned by another node by using the cluster network. The client can experience faster response times if the SMB connection uses a LIF located on the node containing the requested data:

- ONTAP provides this functionality by using Microsoft DFS referrals to inform SMB clients that a requested file or folder in the namespace is hosted somewhere else.

A node makes a referral when it determines that there is anSVM LIF on the node containing the data.

- Automatic node referrals are supported for IPv4 and IPv6 LIF IP addresses.
- Referrals are made based on the location of the root of the share through which the client is connected.
- The referral occurs during SMB negotiation.

The referral is made before the connection is established. After ONTAP refers the SMB client to the target node, the connection is made, and the client accesses data through the referred LIF path from that point on. This allows the clients faster access to the data and avoids extra cluster communication.

If a share spans multiple junction points and some of the junctions are to volumes contained on other nodes, data within the share is spread across multiple nodes. Because ONTAP provides referrals that are local to the root of the share, ONTAP must use the cluster network to retrieve the data contained within these non-local volumes. With this type of namespace architecture, automatic node referrals might not provide significant performance benefits.

If the node hosting the data does not have an available LIF, ONTAP establishes the connection using the LIF chosen by the client. After a file is opened by an SMB client, it continues to access the file through the same referred connection.

If, for any reason, the CIFS server cannot make a referral, there is no disruption to SMB service. The SMB connection is established as if automatic node referrals were not enabled.

Related information

[Improving Microsoft remote copy performance](#)

= Requirements and guidelines for using automatic node referrals

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..../media/

Before you can use SMB automatic node referrals, also known as *autolocation*, you need to be aware of certain requirements, including which versions of ONTAP support the feature. You also need to know about supported SMB protocol versions and certain other special guidelines.

== ONTAP version and license requirements

- All nodes in the cluster must be running a version of ONTAP that supports automatic node referrals.
- Widelinks must be enabled on a SMB share to use autolocation.
- CIFS must be licensed, and an SMB server must exist on the SVMs.

== SMB protocol version requirements

- For SVMs, ONTAP supports automatic node referrals on all versions of SMB.

== SMB client requirements

All Microsoft clients supported by ONTAP support SMB automatic node referrals.

The Interoperability Matrix contains the latest information about which Windows clients ONTAP supports.

mysupport.netapp.com/matrix

== Data LIF requirements

If you want to use a data LIF as a potential referral for SMB clients, you must create data LIFs with both NFS and CIFS enabled.

Automatic node referrals can fail to work if the target node contains data LIFs that are enabled only for the NFS protocol, or enabled only for the SMB protocol.

If this requirement is not met, data access is not affected. The SMB client maps the share using the original LIF that the client used to connect to the SVM.

== NTLM authentication requirements when making a referred SMB connection

NTLM authentication must be allowed on the domain containing the CIFS server and on the domains containing clients that want to use automatic node referrals.

When making a referral, the SMB server refers an IP address to the Windows client. Because NTLM authentication is used when making a connection using an IP address, Kerberos authentication is not performed for referred connections.

This happens because the Windows client cannot craft the service principal name used by Kerberos (which is of the form `service/NetBIOS name` and `service/FQDN`), which means that the client cannot request a Kerberos ticket to the service.

== Guidelines for using automatic node referrals with the home directory feature

When shares are configured with the home directory share property enabled, there can be one or more home directory search paths configured for a home directory configuration. The search paths can point to volumes contained on each node containing SVM volumes. Clients receive a referral and, if an active, local data LIF is available, connect through a referred LIF that is local to the home user's home directory.

There are guidelines when SMB 1.0 clients access dynamic home directories with automatic node referrals enabled. This is because SMB 1.0 clients require the automatic node referral before they have authenticated, which is before the SMB server has the user's name. However, SMB home directory access works correctly for SMB 1.0 clients if the following statements are true:

- SMB home directories are configured to use simple names, such as "%w" (Windows user name) or "%u" (mapped UNIX user name), and not domain-name style names, such as "%d\%w" (domain-name\user-name).
- When creating home directory shares, the CIFS home directory shares names are configured with variables ("%w" or "%u"), and not with static names, such as "HOME".

For SMB 2.x and SMB 3.0 clients, there are no special guidelines when accessing home directories using automatic node referrals.

== Guidelines for disabling automatic node referrals on CIFS servers with existing referred connections

If you disable automatic node referrals after the option has been enabled, clients currently connected to a referred LIF keep the referred connection. Because ONTAP uses DFS referrals as the mechanism for SMB automatic node referrals, clients can even reconnect to the referred LIF after you disable the option until the client's cached DFS referral for the referred connection times out. This is true even in the case of

a revert to a version of ONTAP that does not support automatic node referrals. Clients continue to use referrals until the DFS referral times out from the client's cache.

Autolocation uses SMB automatic node referrals to increase SMB client performance by referring clients to the LIF on the node that owns the data volume of an SVM. When an SMB client connects to an SMB share hosted on an SVM, it might connect using a LIF on a node that does not own the requested data and uses cluster interconnect network to retrieve data. The client can experience faster response times if the SMB connection uses a LIF located on the node containing the requested data.

ONTAP provides this functionality by using Microsoft Distributed File System (DFS) referrals to inform SMB clients that a requested file or folder in the namespace is hosted somewhere else. A node makes a referral when it determines that there is an SVM LIF on the node containing the data. Referrals are made based on the location of the root of the share through which the client is connected.

The referral occurs during SMB negotiation. The referral is made before the connection is established. After ONTAP refers the SMB client to the target node, the connection is made, and the client accesses data through the referred LIF path from that point on. This allows the clients faster access to the data and avoids extra cluster communication.

== Guidelines for using automatic node referrals with Mac OS clients

Mac OS X clients do not support SMB automatic node referrals, even though the Mac OS supports Microsoft's Distributed File System (DFS). Windows clients make a DFS referral request before connecting to an SMB share. ONTAP provides a referral to a data LIF found on the same node that hosts the requested data, which leads to improved client response times. Although the Mac OS supports DFS, Mac OS clients do not behave exactly like Windows clients in this area.

= Support for SMB automatic node referrals

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

Before you enable SMB automatic node referrals, you should be aware that certain ONTAP functionality does not support referrals.

- The following types of volumes do not support SMB automatic node referrals:
 - Read-only members of a load-sharing mirror
 - Destination volume of a data-protection mirror
- Node referrals do not move alongside a LIF move.

If a client is using a referred connection over an SMB 2.x or SMB 3.0 connection and a data LIF moves nondisruptively, the client continues to use the same referred connection, even if the LIF is no longer local to the data.

- Node referrals do not move alongside a volume move.

If a client is using a referred connection over any SMB connection and a volume move occurs, the client continues to use the same referred connection, even if the volume is no longer located on the same node as the data LIF.

= Enable or disable SMB automatic node referrals

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can enable SMB automatic node referrals to increase SMB client access performance. You can disable automatic node referrals if you do not want ONTAP to make referrals to SMB clients.

Before you begin

A CIFS server must be configured and running on the storage virtual machine (SVM).

About this task

The SMB automatic node referrals functionality is disabled by default. You can enable or disable this functionality on each SVM as required.

This option is available at the advanced privilege level.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. Enable or disable SMB automatic node referrals as required:

If you want SMB automatic node referrals to be...	Enter the following command...
Enabled	<code>vserver cifs options modify -vserver vserver_name -is-referral-enabled true</code>
Disabled	<code>vserver cifs options modify -vserver vserver_name -is-referral-enabled false</code>

The option setting takes effect for new SMB sessions. Clients with existing connection can utilize node referral only when their existing cache timeout expires.

3. Switch to the admin privilege level: `set -privilege admin`

Related information

[Available SMB server options](#)

= Use statistics to monitor automatic node referral activity

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

To determine how many SMB connections are referred, you can monitor automatic node referral activity by using the `statistics` command. By monitoring referrals you can determine the extent to which automatic referrals are locating connections on nodes that host the shares and whether you should redistribute your data LIFs to provide better local access to shares on the CIFS server.

About this task

The `cifs` object provides several counters at the advanced privilege level that are helpful when monitoring SMB automatic node referrals:

- `node_referral_issued`

Number of clients that have been issued a referral to the share root's node after the client connected using a LIF hosted by a node different from the share root's node.

- `node_referral_local`

Number of clients that connected using a LIF hosted by the same node that hosts the share root. Local access generally provides optimal performance.

- `node_referral_not_possible`

Number of clients that have not been issued a referral to the node hosting the share root after connecting using a LIF hosted by a node different from the share root's node. This is because an active data LIF for the share root's node was not found.

- `node_referral_remote`

Number of clients that connected using a LIF hosted by a node different from the node that hosts the share root. Remote access might result in degraded performance.

You can monitor automatic node referral statistics on your storage virtual machine (SVM) by collecting and viewing data for a specific time period (a sample). You can view data from the sample if you do not stop data collection. Stopping data collection gives you a fixed sample. Not stopping data collection gives you the ability to get updated data that you can use to compare against previous queries. The comparison can help you identify performance trends.

To evaluate and use the information you gather from the `statistics` command, you should understand the distribution of clients in your environments.

Steps

1. Set the privilege level to advanced: `set -privilege advanced`
2. View automatic node referral statistics by using the `statistics` command.

This example views automatic node referral statistics by collecting and viewing data for a sampled time period:

- a. Start the collection: `statistics start -object cifs -instance vs1 -sample-id sample1`

```
Statistics collection is being started for Sample-id: sample1
```

- b. Wait for the desired collection time to elapse.
- c. Stop the collection: `statistics stop -sample-id sample1`

```
Statistics collection is being stopped for Sample-id: sample1
```

- d. View the automatic node referral statistics: `statistics show -sample-id sample1 -counter node`

```
Object: cifs
Instance: vs1
Start-time: 2/4/2013 19:27:02
End-time: 2/4/2013 19:30:11
Cluster: cluster1
```

Counter	Value
<hr/>	
node_name	node1
node_referral_issued	0
node_referral_local	1
node_referral_not_possible	2
node_referral_remote	2
<hr/>	
node_name	node2
node_referral_issued	2
node_referral_local	1
node_referral_not_possible	0
node_referral_remote	2
<hr/>	

Output displays counters for all nodes participating in SVM vs1. For clarity, only output fields related to automatic node referral statistics are provided in the example.

3. Return to the admin privilege level: `set -privilege admin`

= Provide folder security on shares with access-based enumeration

= Provide folder security on shares with access-based enumeration overview

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

When access-based enumeration (ABE) is enabled on an SMB share, users who do not have permission to access a folder or file contained within the share (whether through individual or group permission restrictions) do not see that shared resource displayed in their environment.

Conventional share properties allow you to specify which users (individually or in groups) have permission to view or modify files or folders contained within the share. However, they do not allow you to control whether folders or files within the share are visible to users who do not have permission to access them. This could pose problems if the names of these folders or files within the share describe sensitive information, such as the names of customers or products under development.

Access-based enumeration (ABE) extends share properties to include the enumeration of files and folders within the share. ABE therefore enables you to filter the display of files and folders within the share based on user access rights. In addition to protecting sensitive information in your workplace, ABE enables you to simplify the display of large directory structures for the benefit of users who do not need access to your full range of content.

= Enable or disable access-based enumeration on SMB shares

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can enable or disable access-based enumeration (ABE) on SMB shares to allow or prevent users from seeing shared resources that they do not have permission to access.

About this task

By default, ABE is disabled.

Steps

1. Perform one of the following actions:

If you want to...	Enter the command...
Enable ABE on a new share	vserver cifs share create -vserver vserver_name -share-name share_name -path path -share-properties access-based-enumeration You can specify additional optional share settings and additional share properties when you create an SMB share. For more information, see the man page for the vserver cifs share create command.
Enable ABE on an existing share	vserver cifs share properties add -vserver vserver_name -share-name share_name -share-properties access-based-enumeration Existing share properties are preserved. The ABE share property is added to the existing list of share properties.
Disable ABE on an existing share	vserver cifs share properties remove -vserver vserver_name -share-name share_name -share-properties access-based-enumeration Other share properties are preserved. Only the ABE share property is removed from the list of share properties.

2. Verify that the share configuration is correct by using the `vserver cifs share show` command.

Examples

The following example creates an ABE SMB share named “sales” with a path of /sales on SVM vs1. The share is created with `access-based-enumeration` as a share property:

```

cluster1::> vserver cifs share create -vserver vs1 -share-name sales
-path /sales -share-properties access-based-
enumeration,oplocks,browsable,changenotify

cluster1::> vserver cifs share show -vserver vs1 -share-name sales

          Vserver: vs1
          Share: sales
CIFS Server NetBIOS Name: VS1
          Path: /sales
Share Properties: access-based-enumeration
                  oplocks
                  browsable
                  changenotify
Symlink Properties: enable
File Mode Creation Mask: -
Directory Mode Creation Mask: -
Share Comment: -
Share ACL: Everyone / Full Control
File Attribute Cache Lifetime: -
          Volume Name: -
Offline Files: manual
Vscan File-Operations Profile: standard

```

The following example adds the access-based-enumeration share property to an SMB share named “data2”:

```

cluster1::> vserver cifs share properties add -vserver vs1 -share-name
data2 -share-properties access-based-enumeration

cluster1::> vserver cifs share show -vserver vs1 -share-name data2
-fields share-name,share-properties
server  share-name share-properties
-----
-----
vs1      data2      oplocks,browsable,changenotify,access-based-
enumeration

```

[Adding or removing share properties on an existing SMB share](#)

= Enable or disable access-based enumeration from a Windows client

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can enable or disable access-based enumeration (ABE) on SMB shares from a Windows client, which allows you to configure this share setting without needing to connect to the CIFS server.

Steps

1. From a Windows client that supports ABE, enter the following command: `abecmd [/enable | /disable] [/server CIFS_server_name] {/all | share_name}`

For more information about the `abecmd` command, see your Windows client documentation.

= NFS and SMB file and directory naming dependencies

= NFS and SMB file and directory naming dependencies overview

:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

File and directory naming conventions depend on both the network clients' operating systems and the file-sharing protocols, in addition to language settings on the ONTAP cluster and clients.

The operating system and the file-sharing protocols determine the following:

- Characters a file name can use
- Case-sensitivity of a file name

ONTAP supports multi-byte characters in file, directory, and qtree names, depending on the ONTAP release.

= Characters a file or directory name can use

:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you are accessing a file or directory from clients with different operating systems, you should use characters that are valid in both operating systems.

For example, if you use UNIX to create a file or directory, do not use a colon (:) in the name because the colon is not allowed in MS-DOS file or directory names. Because restrictions on valid characters vary from one operating system to another, see the documentation for your client operating system for more information about prohibited characters.

= Case-sensitivity of file and directory names in a multiprotocol environment

:icons: font
:relative_path: ./smb-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

File and directory names are case-sensitive for NFS clients and case-insensitive but case-preserving for SMB clients. You must understand what the implications are in a multiprotocol environment and the actions you might need to take when specifying the path while creating SMB shares and when accessing data within the shares.

If an SMB client creates a directory named `testdir`, both SMB and NFS clients display the file name as `testdir`. However, if an SMB user later tries to create a directory name `TESTDIR`, the name is not allowed because, to the SMB client, that name currently exists. If an NFS user later creates a directory named `TESTDIR`, NFS and SMB clients display the directory name differently, as follows:

- On NFS clients, you see both directory names as they were created, for example `testdir` and `TESTDIR`, because directory names are case-sensitive.
- SMB clients use the 8.3 names to distinguish between the two directories. One directory has the base file name. Additional directories are assigned an 8.3 file name.
 - On SMB clients, you see `testdir` and `TESTDI~1`.
 - ONTAP creates the `TESTDI~1` directory name to differentiate the two directories.

In this case, you must use the 8.3 name when specifying a share path while creating or modifying a share on a storage virtual machine (SVM).

Similarly for files, if an SMB client creates `test.txt`, both SMB and NFS clients display the file name as `text.txt`. However, if an SMB user later tries to create `Test.txt`, the name is not allowed because, to the SMB client, that name currently exists. If an NFS user later creates a file named `Test.txt`, NFS and SMB clients display the file name differently, as follows:

- On NFS clients, you see both file names as they were created, `test.txt` and `Test.txt`, because file names are case-sensitive.
- SMB clients use the 8.3 names to distinguish between the two files. One file has the base file name. Additional files are assigned an 8.3 file name.
 - On SMB clients, you see `test.txt` and `TEST~1.TXT`.
 - ONTAP creates the `TEST~1.TXT` file name to differentiate the two files.

If you have enabled or modified character mapping using the Vserver CIFS character-mapping commands, a normally case-insensitive Windows lookup becomes case-sensitive.

= How ONTAP creates file and directory names

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

ONTAP creates and maintains two names for files or directories in any directory that has access from an SMB client: the original long name and a name in 8.3 format.

For file or directory names that exceed the eight character name or the three character extension limit (for files), ONTAP generates an 8.3-format name as follows:

- It truncates the original file or directory name to six characters, if the name exceeds six characters.
- It appends a tilde (~) and a number, one through five, to file or directory names that are no longer unique after being truncated.

If it runs out of numbers because there are more than five similar names, it creates a unique name that bears no relation to the original name.

- In the case of files, it truncates the file name extension to three characters.

For example, if an NFS client creates a file named `specifications.html`, the 8.3 format file name created by ONTAP is `specif~1.htm`. If this name already exists, ONTAP uses a different number at the end of the file name. For example, if an NFS client then creates another file named `specifications_new.html`, the 8.3 format of `specifications_new.html` is `specif~2.htm`.

= How ONTAP handles multi-byte file, directory, and qtree names

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../smb-admin/..media/

Beginning with ONTAP 9.5, support for 4-byte UTF-8 encoded names enables the creation and display of file, directory, and tree names that include Unicode supplementary characters outside the Basic Multilingual Plane (BMP). In earlier releases, these supplementary characters did not display correctly in multiprotocol environments.

To enable support for 4-byte UTF-8 encoded names, a new `utf8mb4` language code is available for the `vserver` and `volume` command families.

- You must create a new volume in one of the following ways:
 - Setting the `volume -language` option explicitly: `volume create -language utf8mb4 {...}`
 - Inheriting the `volume -language` option from an SVM that has been created with or modified for the option: `vserver [create|modify] -language utf8mb4 {...}` `volume create {...}`
- You cannot modify existing volumes for `utf8mb4` support; you must create a new `utf8mb4`-ready volume, and then migrate the data using client-based copy tools.

You can update SVMs for `utf8mb4` support, but existing volumes retain their original language codes.

LUN names with 4-byte UTF-8 characters are not currently supported.

- Unicode character data is typically represented in Windows file systems applications using the 16-bit Unicode Transformation Format (UTF-16) and in NFS file systems using the 8-bit Unicode Transformation Format (UTF-8).

In releases prior to ONTAP 9.5, names including UTF-16 supplementary characters that were created by Windows clients were correctly displayed to other Windows clients but were not translated correctly to UTF-8 for NFS clients. Similarly, names with UTF-8 supplementary characters by created NFS clients were not translated correctly to UTF-16 for Windows clients.

- When you create file names on systems running ONTAP 9.4 or earlier that contain valid or invalid supplementary characters, ONTAP rejects the file name and returns an invalid file name error.

To avoid this issue, use only BMP characters in file names and avoid using supplementary characters, or upgrade to ONTAP 9.5 or later.

Beginning with ONTAP 9, Unicode characters are allowed in qtree names.

- You can use either the `volume qtree` command family or System Manager to set or modify qtree names.
- qtree names can include multi-byte characters in Unicode format, such as Japanese and Chinese

characters.

- In releases before ONTAP 9.5, only BMP characters (that is, those that could be represented in 3 bytes) were supported.

In releases before ONTAP 9.5, the junction-path of the qtree's parent volume can contain qtree and directory names with Unicode characters. The `volume show` command displays these names correctly when the parent volume has a UTF-8 language setting. However, if the parent volume language is not one of the UTF-8 language settings, some parts of the junction-path are displayed using a numeric NFS alternate name.

- In 9.5 and later releases, 4-byte characters are supported in qtree names, provided that the qtree is in a volume enabled for `utf8mb4`.

= Configure character mapping for SMB file name translation on volumes

:icons: font

:relative_path: ./smb-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

NFS clients can create file names that contain characters that are not valid for SMB clients and certain Windows applications. You can configure character mapping for file name translation on volumes to allow SMB clients to access files with NFS names that would otherwise not be valid.

About this task

When files created by NFS clients are accessed by SMB clients, ONTAP looks at the name of the file. If the name is not a valid SMB file name (for example, if it has an embedded colon ":" character), ONTAP returns the 8.3 file name that is maintained for each file. However, this causes problems for applications that encode important information into long file names.

Therefore, if you are sharing a file between clients on different operating systems, you should use characters in the file names that are valid in both operating systems.

However, if you have NFS clients that create file names containing characters that are not valid file names for SMB clients, you can define a map that converts the invalid NFS characters into Unicode characters that both SMB and certain Windows applications accept. For example, this functionality supports the CATIA MCAD and Mathematica applications as well as other applications that have this requirement.

You can configure character mapping on a volume-by-volume basis.

You must keep the following in mind when configuring character mapping on a volume:

- Character mapping is not applied across junction points.

You must explicitly configure character mapping for each junction volume.

- You must make sure that the Unicode characters that are used to represent invalid or illegal characters are characters that do not normally appear in file names; otherwise, unwanted mappings occur.

For example, if you try to map a colon (:) to a hyphen (-) but the hyphen (-) was used in the file name correctly, a Windows client trying to access a file named "a-b" would have its request mapped to the NFS name of "a:b" (not the desired outcome).

- After applying character mapping, if the mapping still contains an invalid Windows character, ONTAP falls back to Windows 8.3 file names.
- In FPolicy notifications, NAS audit logs, and security trace messages, the mapped file names are shown.
- When a SnapMirror relation of type DP is created, the source volume's character mapping is not replicated on the destination DP volume.
- Case sensitivity: Because the mapped Windows names turn into NFS names, the lookup of the names follows NFS semantics. That includes the fact that NFS lookups are case-sensitive. This means that the applications accessing mapped shares must not rely on Windows case-insensitive behavior. However, the 8.3 name is available, and that is case-insensitive.
- Partial or invalid mappings: After mapping a name to return to clients doing directory enumeration ("dir"), the resulting Unicode name is checked for Windows validity. If that name still has invalid characters in it, or if it is otherwise invalid for Windows (e.g. it ends in "." or blank) the 8.3 name is returned instead of the invalid name.

Step

1. Configure character mapping: +

```
vserver cifs character-mapping create -vserver vserver_name -volume
volume_name -mapping mapping_text, ... +
```

The mapping consists of a list of source-target character pairs separated by ":". The characters are Unicode characters entered using hexadecimal digits. For example: 3C:E03C. +

The first value of each *mapping_text* pair that is separated by a colon is the hexadecimal value of the NFS character you want to translate, and the second value is the Unicode value that SMB uses. The mapping pairs must be unique (a one-to-one mapping should exist).

- Source mapping +

The following table shows the permissible Unicode character set for source mapping:

+

Unicode character	Printed character	Description
0x01-0x19	Not applicable	Non-printing control characters
0x5C	\	Backslash
0x3A	:	Colon
0x2A	*	Asterisk
0x3F	?	Question mark
0x22	"	Quotation mark
0x3C	<	Less than

Unicode character	Printed character	Description
0x3E	>	Greater than
0x7C		Vertical line
0xB1	±	Plus-minus sign

- Target mapping

You can specify target characters in the “Private Use Area” of Unicode in the following range: U+E0000...U+F8FF.

Example

The following command creates a character mapping for a volume named “data” on storage virtual machine (SVM) vs1:

```
cluster1::> vserver cifs character-mapping create -volume data -mapping
3c:e17c,3e:f17d,2a:f745
cluster1::> vserver cifs character-mapping show

Vserver          Volume Name  Character Mapping
-----          -----      -----
vs1              data        3c:e17c, 3e:f17d, 2a:f745
```

= SMB configuration for Microsoft Hyper-V and SQL Server

= SMB configuration for Microsoft Hyper-V and SQL Server overview

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/./media/

ONTAP features allow you to enable nondisruptive operations for two Microsoft applications over the SMB protocol: Microsoft Hyper-V and Microsoft SQL Server.

You should use these procedures if you want to implement SMB nondisruptive operations under the following circumstances:

- Basic SMB protocol file access has been configured.
- You want to enable SMB 3.0 or later file shares residing in SVMs to store the following objects:
 - Hyper-V virtual machine files
 - SQL Server system databases

Related information

For additional information about ONTAP technology and interaction with external services, see these Technical Reports (TRs):

= Configure ONTAP for Microsoft Hyper-V and SQL Server over SMB solutions

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/./media/

You can use continuously available SMB 3.0 and later file shares to store Hyper-V virtual machine files or SQL Server system databases and user databases on volumes residing in SVMs, while at the same time providing nondisruptive operations (NDOs) for both planned and unplanned events.

== Microsoft Hyper-V over SMB

To create a Hyper-V over SMB solution, you must first configure ONTAP to provide storage services for Microsoft Hyper-V servers. Additionally, you must also configure Microsoft clusters (if using a clustered configuration), Hyper-V servers, continuously available SMB 3.0 connections to the shares hosted by the CIFS server, and, optionally, backup services to protect the virtual machine files that are stored on SVM volumes.

The Hyper-V servers must be configured on Windows 2012 Server or later. Both stand-alone and clustered Hyper-V server configurations are supported.

- For information about creating Microsoft clusters and Hyper-V servers, see the Microsoft web site.
- SnapManager for Hyper-V is a host-based application that facilitates rapid, Snapshot copy-based backup services, designed to integrate with Hyper-V over SMB configurations.

For information about using SnapManager with Hyper-V over SMB configurations, see *SnapManager for Hyper-V Installation and Administration Guide*.

== Microsoft SQL Server over SMB

To create a SQL Server over SMB solution, you must first configure ONTAP to provide storage services for the Microsoft SQL Server application. Additionally, you must also configure Microsoft clusters (if using a clustered configuration). You would then install and configure SQL Server on the Windows servers and create continuously available SMB 3.0 connections to the shares hosted by the CIFS server. You can optionally configure backup services to protect the database files that are stored on SVM volumes.

SQL Server must be installed and configured on Windows 2012 Server or later. Both stand-alone and clustered configurations are supported.

- For information about creating Microsoft clusters and installing and configuring SQL Server, see the Microsoft web site.
- SnapManager for Microsoft SQL Server is a host-based application that facilitates rapid, Snapshot copy-based backup services, designed to integrate with SQL Server over SMB configurations.

For information about using SnapManager for Microsoft SQL Server, see the *SnapManager for Microsoft SQL Server Installation and Administration Guide*.

= Nondisruptive operations for Hyper-V and SQL Server over SMB

= What nondisruptive operations for Hyper-V and SQL Server over SMB means

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Nondisruptive operations for Hyper-V and SQL Server over SMB refers to the combination of capabilities that enable the application servers and the contained virtual machines or databases to remain online and to provide continuous availability during many administrative tasks. This includes both planned and unplanned downtime of the storage infrastructure.

Supported nondisruptive operations for application servers over SMB include the following:

- Planned takeover and giveback
- Unplanned takeover
- Upgrade
- Planned aggregate relocation (ARL)
- LIF migration and failover
- Planned volume move

= Protocols that enable nondisruptive operations over SMB

```
:icons: font
:relative_path: ./smb-hyper-v-sql/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

Along with the release of SMB 3.0, Microsoft has released new protocols to provide the capabilities necessary to support nondisruptive operations for Hyper-V and SQL Server over SMB.

ONTAP uses these protocols when providing nondisruptive operations for application servers over SMB:

- SMB 3.0
- Witness

= Key concepts about nondisruptive operations for Hyper-V and SQL Server over SMB

```
:icons: font
:relative_path: ./smb-hyper-v-sql/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

There are certain concepts about nondisruptive operations (NDOs) that you should understand before you configure your Hyper-V or SQL Server over SMB solution.

- **Continuously available share**

An SMB 3.0 share that has the continuously available share property set. Clients connecting through continuously available shares can survive disruptive events such as takeover, giveback, and aggregate relocation.

- **Node**

A single controller that is a member of a cluster. To distinguish between the two nodes in an SFO pair, one node is sometimes called the *local node* and the other node is sometimes called the *partner node* or *remote node*. The primary owner of the storage is the local node. The secondary owner, which takes control of the storage when the primary owner fails, is the partner node. Each node is the primary owner of its storage and secondary owner for its partner's storage.

- **Nondisruptive aggregate relocation**

The ability to move an aggregate between partner nodes within an SFO pair in a cluster without interrupting client applications.

- **Nondisruptive failover**

See *Takeover*.

- **Nondisruptive LIF migration**

The ability to perform a LIF migration without interrupting client applications that are connected to the cluster through that LIF. For SMB connections, this is only possible for clients that connect using SMB 2.0 or later.

- **Nondisruptive operations**

The ability to perform major ONTAP management and upgrade operations as well as withstand node failures without interrupting client applications. This term refers to the collection of nondisruptive

takeover, nondisruptive upgrade, and nondisruptive migration capabilities as a whole.

- **Nondisruptive upgrade**

The ability to upgrade node hardware or software without application interruption.

- **Nondisruptive volume move**

The ability to move a volume freely throughout the cluster without interrupting any applications that are using the volume. For SMB connections, all versions of SMB support nondisruptive volume moves.

- **Persistent handles**

A property of SMB 3.0 that allows continuously available connections to transparently reconnect to the CIFS server in the event of a disconnection. Similar to durable handles, persistent handles are maintained by the CIFS server for a period of time after communication to the connecting client is lost. However, persistent handles have more resilience than durable handles. In addition to giving the client a chance to reclaim the handle within a 60-second window after reconnecting, the CIFS server denies access to any other clients requesting access to the file during that 60-second window.

Information about persistent handles is mirrored on the SFO partner's persistent storage, which allows clients with disconnected persistent handles to reclaim the durable handles after an event where the SFO partner takes ownership of the node's storage. In addition to providing nondisruptive operations in the event of LIF moves (which durable handles support), persistent handles provide nondisruptive operations for takeover, giveback, and aggregate relocation.

- **SFO giveback**

Returning aggregates to their home locations when recovering from a takeover event.

- **SFO pair**

A pair of nodes whose controllers are configured to serve data for each other if one of the two nodes stops functioning. Depending on the system model, both controllers can be in a single chassis, or the controllers can be in separate chassis. Known as an HA pair in a two-node cluster.

- **Takeover**

The process by which the partner takes control of the storage when the primary owner of that storage fails. In the context of SFO, failover and takeover are synonymous.

= How SMB 3.0 functionality supports nondisruptive operations over SMB shares

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

SMB 3.0 provides crucial functionality that enables support for nondisruptive operations for Hyper-V and SQL Server over SMB shares. This includes the *continuously-available share* property and a type of file handle known as a *persistent handle* that allow SMB clients to reclaim file open state and transparently reestablish SMB connections.

Persistent handles can be granted to SMB 3.0 capable clients that connect to a share with the

continuously available share property set. If the SMB session is disconnected, the CIFS server retains information about persistent handle state. The CIFS server blocks other client requests during the 60-second period in which the client is allowed to reconnect, thus allowing the client with the persistent handle to reclaim the handle after a network disconnection. Clients with persistent handles can reconnect by using one of the data LIFs on the storage virtual machine (SVM), either by reconnecting through the same LIF or through a different LIF.

Aggregate relocation, takeover, and giveback all occur between SFO pairs. To seamlessly manage the disconnection and reconnection of sessions with files that have persistent handles, the partner node maintains a copy of all persistent handle lock information. Whether the event is planned or unplanned, the SFO partner can nondisruptively manage the persistent handle reconnects. With this new functionality, SMB 3.0 connections to the CIFS server can transparently and nondisruptively fail over to another data LIF assigned to the SVM in what traditionally has been disruptive events.

Although the use of persistent handles allows the CIFS server to transparently fail over SMB 3.0 connections, if a failure causes the Hyper-V application to fail over to another node in the Windows Server cluster, the client has no way to reclaim the file handles of these disconnected handles. In this scenario, file handles in the disconnected state can potentially block access of the Hyper-V application if it is restarted on a different node. “Failover Clustering” is a part of SMB 3.0 that addresses this scenario by providing a mechanism to invalidate stale, conflicting handles. Using this mechanism, a Hyper-V cluster can recover quickly when Hyper-V cluster nodes fail.

= What the Witness protocol does to enhance transparent failover
:icons: font
:relative_path: ./smb-hyper-v-sql/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The Witness protocol provides enhanced client failover capabilities for SMB 3.0 continuously available shares (CA shares). Witness facilitates faster failover because it bypasses the LIF failover recovery period. It notifies application servers when a node is unavailable without needing to wait for the SMB 3.0 connection to time out.

The failover is seamless, with applications running on the client not being aware that a failover occurred. If Witness is not available, failover operations still occur successfully, but failover without Witness is less efficient.

Witness enhanced failover is possible when the following requirements are met:

- It can only be used with SMB 3.0-capable CIFS servers that have SMB 3.0 enabled.
- The shares must use SMB 3.0 with the continuous availability share property set.
- The SFO partner of the node to which the application servers are connected must have at least one operational data LIF assigned to the storage virtual machine (SVM) hosting data for the application servers.

The Witness protocol operates between SFO pairs. Because LIFs can migrate to any node within the cluster, any node might need to be the witness for its SFO partner. The Witness protocol cannot provide rapid failover of SMB connections on a given node if the SVM hosting data for the application servers does not have an active data LIF on the partner node. Therefore, every node in the cluster must have at least one data LIF for each SVM hosting one of these configurations.

- The application servers must connect to the CIFS server by using the CIFS server name that is stored in DNS instead of by using individual LIF IP addresses.

= How the Witness protocol works

:icons: font

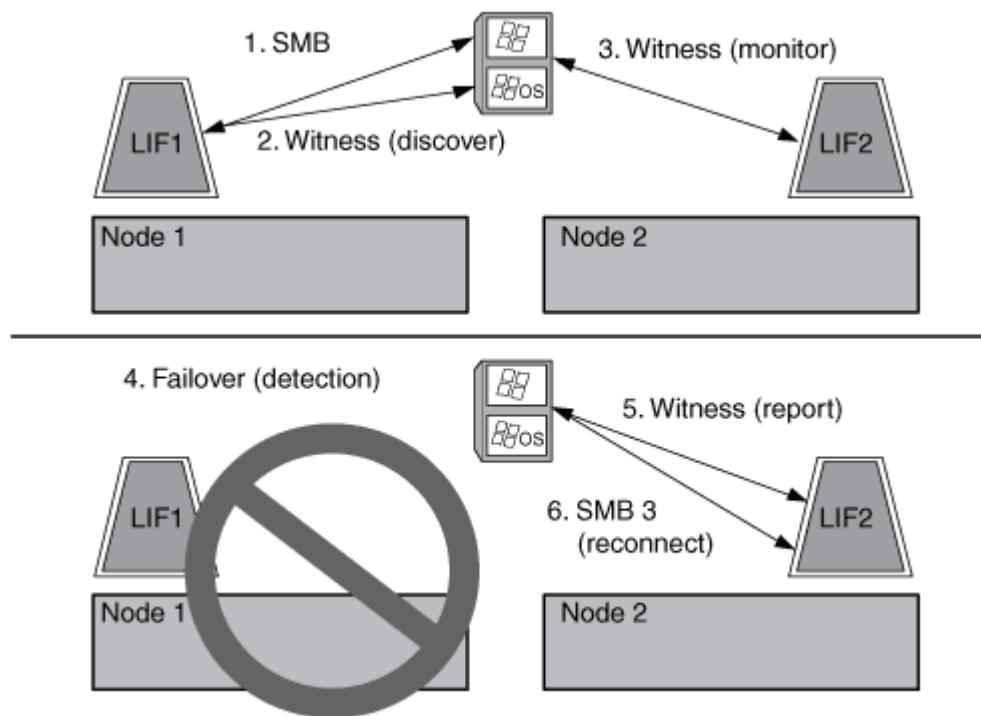

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ONTAP implements the Witness protocol by using a node's SFO partner as the witness. In the event of a failure, the partner quickly detects the failure and notifies the SMB client.

The Witness protocol provides enhanced failover using the following process:

1. When the application server establishes a continuously available SMB connection to Node1, the CIFS server informs the application server that Witness is available.
2. The application server requests the IP addresses of the Witness server from Node1 and receives a list of Node2 (the SFO partner) data LIF IP addresses assigned to the storage virtual machine (SVM).
3. The application server chooses one of the IP addresses, creates a Witness connection to Node2, and registers to be notified if the continuously available connection on Node1 must move.
4. If a failover event occurs on Node1, Witness facilitates failover events, but is not involved with giveback.
5. Witness detects the failover event and notifies the application server through the Witness connection that the SMB connection must move to Node2.
6. The application server moves the SMB session to Node2 and recovers the connection without interruption to client access.

= Share-based backups with Remote VSS

= Share-based backups with Remote VSS overview

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can use Remote VSS to perform share-based backups of Hyper-V virtual machine files that are stored on a CIFS server.

Microsoft Remote VSS (Volume Shadow Copy Services) is an extension of the existing Microsoft VSS infrastructure. Previously, VSS could be used for backup services only for data stored on local disk. This limited the use of VSS to applications that store data either on a local disk or on SAN-based storage. With Remote VSS, Microsoft has extended the VSS infrastructure to support the shadow copying of SMB shares. Server applications such as Hyper-V are now storing VHD files on SMB file shares. With these new extensions, it is possible to take application consistent shadow copies for virtual machines that store data and configuration files on shares.

= Remote VSS concepts

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin../media/

You should be aware of certain concepts that are required to understand how Remote VSS (Volume Shadow Copy Service) is used by backup services with Hyper-V over SMB configurations.

- **VSS (Volume Shadow Copy Service)**

A Microsoft technology that is used to take backup copies or snapshots of data on a specific volume at a specific point in time. VSS coordinates among data servers, backup applications, and storage management software to support the creation and management of consistent backups.

- **Remote VSS (Remote Volume Shadow Copy Service)**

A Microsoft technology that is used to take share-based backup copies of data that is in a data-consistent state at a specific point in time where the data is accessed over SMB 3.0 shares. Also known as *Volume Shadow Copy Service*.

- **Shadow copy**

A duplicate set of data contained in the share at a well-defined instant in time. Shadow copies are used to create consistent point-in-time backups of data, allowing the system or applications to continue updating data on the original volumes.

- **Shadow copy set**

A collection of one or more shadow copies, with each shadow copy corresponding to one share. The shadow copies within a shadow copy set represent all the shares that must be backed up in the same operation. The VSS client on the VSS-enabled application identifies which shadow copies to include in the set.

- **Shadow copy set automatic recovery**

The part of the backup process for remote VSS-enabled backup applications where the replica directory containing the shadow copies is made point-in-time consistent. At the start of the backup, the VSS client on the application triggers the application to take software checkpoints on the data scheduled for backup (the virtual machine files in the case of Hyper-V). The VSS client then allows the applications to continue. After the shadow copy set is created, Remote VSS makes the shadow copy set writeable and exposes the writeable copy to the applications. The application prepares the shadow copy set for backup by performing an automatic recovery using the software checkpoint taken

earlier. Automatic recovery brings the shadow copies into a consistent state by unrolling the changes made to the files and directories since the checkpoint was created. Automatic recovery is an optional step for VSS-enabled backups.

- **Shadow copy ID**

A GUID that uniquely identifies a shadow copy.

- **Shadow copy set ID**

A GUID that uniquely identifies a collection of shadow copy IDs to the same server.

- **SnapManager for Hyper-V**

The software that automates and simplifies backup-and-restore operations for Microsoft Windows Server 2012 Hyper-V. SnapManager for Hyper-V uses Remote VSS with automatic recovery to back up Hyper-V files over SMB shares.

Related information

[Key concepts about nondisruptive operations for Hyper-V and SQL Server over SMB](#)

[Share-based backups with Remote VSS](#)

= Example of a directory structure used by Remote VSS

```
:icons: font  
:relative_path: ./smb-hyper-v-sql/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

Remote VSS traverses the directory structure that stores Hyper-V virtual machine files as it creates shadow copies. It is important to understand what an appropriate directory structure is, so that you can successfully create backups of virtual machine files.

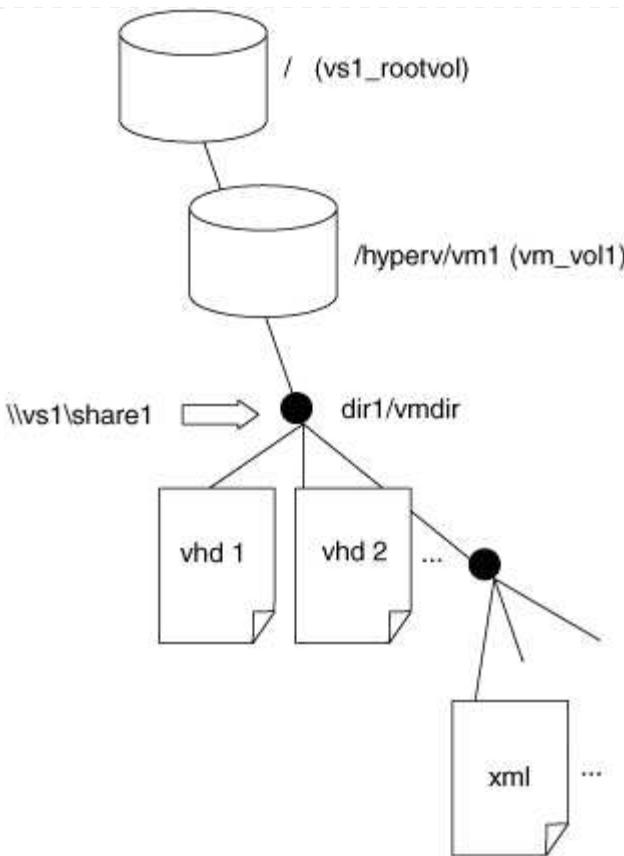

A supported directory structure for the successful creation of shadow copies conforms to the following requirements:

- Only directories and regular files are present within the directory structure that is used to store virtual machine files.

The directory structure does not contain junctions, links, or non-regular files.

- All files for a virtual machine reside within a single share.
- The directory structure that is used to store virtual machine files does not exceed the configured depth of the shadow copy directory.
- The root directory of the share contains only virtual machine files or directories.

In the following illustration, the volume named `vm_vol1` is created with a junction point at `/hyperv/vm1` on storage virtual machine (SVM) `vs1`. Subdirectories to contain the virtual machine files are created under the junction point. The virtual machine files of the Hyper-V server are accessed over share1 that has the path `/hyperv/vm1/dir1/vmdir`. The shadow copy service creates shadow copies of all the virtual machine files that are contained within the directory structure under share1 (up to the configured depth of the shadow copy directory).

= How SnapManager for Hyper-V manages Remote VSS-based backups for Hyper-V over SMB
 :icons: font
 :relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can use SnapManager for Hyper-V to manage Remote VSS-based backup services. There are benefits to using SnapManager for Hyper-V managed backup service to create space efficient backup sets.

Optimizations to SnapManager for Hyper-V managed backups include the following:

- SnapDrive integration with ONTAP provides performance optimization when discovering SMB share location.

ONTAP provides SnapDrive with the name of the volume where the share resides.

- SnapManager for Hyper-V specifies the list of virtual machine files in the SMB shares that the shadow copy service needs to copy.

By providing a targeted list of virtual machine files, the shadow copy service does not need to create shadow copies of all the files in the share.

- The storage virtual machine (SVM) retains the Snapshot copies for SnapManager for Hyper-V to use for restores.

There is no backup phase. The backup is the space-efficient Snapshot copy.

SnapManager for Hyper-V provides backup and restore capabilities for HyperV over SMB using the

following process:

1. Preparing for the shadow copy operation

The SnapManager for Hyper-V application's VSS client sets up the shadow copy set. The VSS client gathers information about what shares to include in the shadow copy set and provides this information to ONTAP. A set might contain one or more shadow copies, and one shadow copy corresponds to one share.

2. Creating the shadow copy set (if automatic-recovery is used)

For every share included in the shadow copy set, ONTAP creates a shadow copy and makes the shadow copy writable.

3. Exposing the shadow copy set

After ONTAP creates the shadow copies, they are exposed to SnapManager for Hyper-V so that the application's VSS writers can perform automatic recovery.

4. Automatically recovering the shadow copy set

During the shadow copy set creation, there is a period of time when active changes are occurring to the files included in the backup set. The application's VSS writers must update the shadow copies to make sure that they are in a completely consistent state prior to backup.

The way that automatic recovery is done is application specific. Remote VSS is not involved in this phase.

5. Completing and cleaning up the shadow copy set

The VSS client notifies ONTAP after it completes automatic recovery. The shadow copy set is made read-only and then is ready for backup. When using SnapManager for Hyper-V for backup, the files in a Snapshot copy become the backup; therefore, for the backup phase, a Snapshot copy is created for every volume containing shares in the backup set. After the backup is complete, the shadow copy set is removed from the CIFS server.

= How ODX copy offload is used with Hyper-V and SQL Server over SMB shares

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Offloaded Data Transfer (ODX), also known as *copy offload*, enables direct data transfers within or between compatible storage devices without transferring the data through the host computer. ONTAP ODX copy offload provides you with performance benefits when performing copy operations on your application server over SMB installation.

In non-ODX file transfers, the data is read from the source CIFS server and is transferred across the network to the client computer. The client computer transfers the data back over the network to the destination CIFS server. In summary, the client computer reads the data from the source and writes it to the destination. With ODX file transfers, data is copied directly from the source to the destination.

Because ODX offloaded copies are performed directly between the source and destination storage, there

are significant performance benefits. The performance benefits realized include faster copy time between source and destination, reduced resource utilization (CPU, memory) on the client, and reduced network I/O bandwidth utilization.

This functionality is available on Windows Server 2012 servers. ONTAP ODX copy offload is supported on both SAN LUNs and SMB 3.0 continuously available connections.

The following use cases support using ODX copies and moves:

- Intra-volume

The source and destination files or LUNs are within the same volume.

- Inter-volume, same node, same storage virtual machine (SVM)

The source and destination files or LUNs are on different volumes that are located on the same node. The data is owned by the same SVM.

- Inter-volume, different nodes, same SVM

The source and destination files or LUNs are on different volumes that are located on different nodes. The data is owned by the same SVM.

- Inter-SVM, same node

The source and destination file or LUNs are on different volumes that are located on the same node. The data is owned by different SVMs.

- Inter-SVM, different nodes

The source and destination file or LUNs are on different volumes that are located on different nodes. The data is owned by different SVMs.

Specific use cases for ODX copy offload with Hyper-V solutions include the following:

- You can use ODX copy offload pass-through with Hyper-V to copy data within or across virtual hard disk (VHD) files or to copy data between mapped SMB shares and connected iSCSI LUNs within the same cluster.

This allows copies from guest operating systems to pass through to the underlying storage.

- When creating fixed-sized VHDs, ODX is used for initializing the disk with zeros, using a well-known zeroed token.
- ODX copy offload is used for virtual machine storage migration if the source and destination storage is on the same cluster.

To take advantage of the use cases for ODX copy offload pass-through with Hyper-V, the guest operating system must support ODX and the guest operating system's disks must be SCSI disks backed by storage (either SMB or SAN) that supports ODX. IDE disks on the guest operating system do not support ODX pass-through.

Specific use cases for ODX copy offload with SQL Server solutions include the following:

- You can use ODX copy offload to export and import SQL Server databases between mapped SMB

shares or between SMB shares and connected iSCSI LUNs within the same cluster.

- ODX copy offload is used for database exports and imports if the source and destination storage is on the same cluster.

= Configuration requirements and considerations

= ONTAP and licensing requirements

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You need to be aware of certain ONTAP and licensing requirements when creating SQL Server or Hyper-V over SMB solutions for nondisruptive operations on SVMs.

== ONTAP version requirements

- Hyper-V over SMB

ONTAP supports nondisruptive operations over SMB shares for Hyper-V running on Windows 2012 or later.

- SQL Server over SMB

ONTAP supports nondisruptive operations over SMB shares for SQL Server 2012 or later running on Windows 2012 or later.

For the latest information about supported versions of ONTAP, Windows Server, and SQL Server for nondisruptive operations over SMB shares, see the Interoperability Matrix.

[NetApp Interoperability Matrix Tool](#)

== Licensing requirements

The following licenses are required:

- CIFS
- FlexClone (for Hyper-V over SMB only)

This license is required if Remote VSS is used for backups. The shadow copy service uses FlexClone to create point-in-time copies of files that are then used when creating a backup.

A FlexClone license is optional if you use a backup method that does not use Remote VSS.

= Network and data LIF requirements

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You need to be aware of certain network and data LIF requirements when creating SQL Server or Hyper-V over SMB configurations for nondisruptive operations).

== Network protocol requirements

- IPv4 and IPv6 networks are supported.

- SMB 3.0 or later is required.

SMB 3.0 provides the functionality needed to create the continuously available SMB connections necessary to offer nondisruptive operations.

- DNS servers must contain entries that map the CIFS server name to the IP addresses assigned to the data LIFs on the storage virtual machine (SVM).

The Hyper-V or SQL Server application servers typically make multiple connections over multiple data LIFs when accessing virtual machine or database files. For proper functionality, the application servers must make these multiple SMB connections by using the CIFS server name instead of making multiple connections to multiple unique IP addresses.

Witness also requires the use of the CIFS server's DNS name instead of individual LIF IP addresses.

Beginning with ONTAP 9.4, you can improve throughput and fault tolerance for Hyper-V and SQL server over SMB configurations by enabling SMB Multichannel. To do so, you must have multiple 1G, 10G, or larger NICs deployed on the cluster and clients.

== Data LIF requirements

- The SVM hosting the application server over SMB solution must have at least one operational data LIF on every node in the cluster.

SVM data LIFs can fail over to other data ports within the cluster, including nodes that are not currently hosting data accessed by the application servers. Additionally, because the Witness node is always the SFO partner of a node to which the application server is connected, every node in the cluster is a potential Witness node.

- Data LIFs must not be configured to automatically revert.

After a takeover or giveback event, you should manually revert the data LIFs to their home ports.

- All data LIF IP addresses must have an entry in DNS and all entries must resolve to the CIFS server name.

The application servers must connect to SMB shares by using the CIFS server name. You must not configure the application servers to make connections by using the LIF IP addresses.

- If the CIFS server name is different from the SVM name, the DNS entries must resolve to the CIFS server name.

= SMB server and volume requirements for Hyper-V over SMB

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

You need to be aware of certain SMB server and volume requirements when creating Hyper-V over SMB configurations for nondisruptive operations.

== SMB server requirements

- SMB 3.0 must be enabled.

This is enabled by default.

- The default UNIX user CIFS server option must be configured with a valid UNIX user account.

The application servers use the machine account when creating an SMB connection. Because all SMB access requires that the Windows user successfully map to a UNIX user account or to the default UNIX user account, ONTAP must be able to map the application server's machine account to the default UNIX user account.

- Automatic node referrals must be disabled (this functionality is disabled by default).

If you want to use automatic node referrals for access to data other than Hyper-V machine files, you must create a separate SVM for that data.

- Both Kerberos and NTLM authentication must be allowed in the domain to which the SMB server belongs.

ONTAP does not advertise the Kerberos service for Remote VSS; therefore, the domain should be set to permit NTLM.

- Shadow copy functionality must be enabled.

This functionality is enabled by default.

- The Windows domain account that the shadow copy service uses when creating shadow copies must be a member of the SMB server local BUILTIN\Administrators or BUILTIN\Backup Operators group.

== Volume requirements

- Volumes used to store virtual machine files must be created as NTFS security-style volumes.

To provide NDOs for application servers using continuously available SMB connections, the volume containing the share must be an NTFS volume. Moreover, it must always have been an NTFS volume. You cannot change a mixed security-style volume or UNIX security-style volume to an NTFS security-style volume and directly use it for NDOs over SMB shares. If you change a mixed security-style volume to an NTFS security style volume and intend to use it for NDOs over SMB shares, you must manually place an ACL at the top of the volume and propagate that ACL to all contained files and folders. Otherwise, virtual machine migrations or database file exports and imports where files are moved to another volume can fail if either the source or the destination volumes were initially created as mixed or UNIX security-style volumes and later changed to NTFS security style.

- For shadow copy operations to succeed, you must have enough available space on the volume.

The available space must be at least as large as the combined space used by all files, directories, and subdirectories contained within the shares included in the shadow copy backup set. This requirement only applies to shadow copies with auto-recovery.

[Microsoft TechNet Library: technet.microsoft.com/en-us/library/](https://technet.microsoft.com/en-us/library/)

= SMB server and volume requirements for SQL Server over SMB

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You need to be aware of certain SMB server and volume requirements when creating SQL Server over SMB configurations for nondisruptive operations.

== SMB server requirements

- SMB 3.0 must be enabled.

This is enabled by default.

- The default UNIX user CIFS server option must be configured with a valid UNIX user account.

The application servers use the machine account when creating an SMB connection. Because all SMB access requires that the Windows user successfully map to a UNIX user account or to the default UNIX user account, ONTAP must be able to map the application server's machine account to the default UNIX user account.

Additionally, SQL Server uses a domain user as the SQL Server service account. The service account must also map to the default UNIX user.

- Automatic node referrals must be disabled (this functionality is disabled by default).

If you want to use automatic node referrals for access to data other than SQL server database files, you must create a separate SVM for that data.

- The Windows user account used for installing SQL Server on ONTAP must be assigned the SeSecurityPrivilege privilege.

This privilege is assigned to the SMB server local BUILTIN\Administrators group.

== Volume requirements

- Volumes used to store virtual machine files must be created as NTFS security-style volumes.

To provide NDOs for application servers using continuously available SMB connections, the volume containing the share must be an NTFS volume. Moreover, it must always have been an NTFS volume. You cannot change a mixed security-style volume or UNIX security-style volume to an NTFS security-style volume and directly use it for NDOs over SMB shares. If you change a mixed security-style volume to an NTFS security style volume and intend to use it for NDOs over SMB shares, you must manually place an ACL at the top of the volume and propagate that ACL to all contained files and folders. Otherwise, virtual machine migrations or database file exports and imports where files are moved to another volume can fail if either the source or the destination volumes were initially created as mixed or UNIX security-style volumes and later changed to NTFS security style.

- Although the volume containing the database files can contain junctions, SQL Server does not cross junctions when creating the database directory structure.
- For SnapManager for Microsoft SQL Server backup operations to succeed, you must have enough available space on the volume.

The volume on which the SQL Server database files reside must be large enough to hold the database directory structure and all contained files residing within the share.

= Continuously available share requirements and considerations for Hyper-V over SMB

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You need to be aware of certain requirements and considerations when configuring continuously available shares for Hyper-V over SMB configurations that support nondisruptive operations.

== Share requirements

- Shares used by the application servers must be configured with the continuously available property set.

Application servers that connect to continuously available shares receive persistent handles that allow them to reconnect nondisruptively to SMB shares and reclaim file locks after disruptive events, such as takeover, giveback, and aggregate relocation.

- If you want to use Remote VSS-enabled backup services, you cannot put Hyper-V files into shares that contain junctions.

In the auto-recovery case, the shadow copy creation fails if a junction is encountered while traversing the share. In the non auto-recovery case, the shadow copy creation does not fail, but the junction does not point to anything.

- If you want to use Remote VSS-enabled backup services with auto-recovery, you cannot put Hyper-V files into shares that contain the following:

- Symlinks, hardlinks, or widelinks
- Non-regular files

The shadow copy creation fails if there are any links or non-regular files in the share to shadow copy. This requirement only applies to shadow copies with auto-recovery.

- For shadow copy operations to succeed, you must have enough available space on the volume (for Hyper-V over SMB only).

The available space must be at least as large as the combined space used by all files, directories, and subdirectories contained within the shares included in the shadow copy backup set. This requirement only applies to shadow copies with auto-recovery.

- The following share properties must not be set on continuously available shares used by the application servers:

- Home directory
- Attribute caching
- BranchCache
- Access-based enumerations

== Considerations

- Quotas are supported on continuously available shares.
- The following functionality is not supported for Hyper-V over SMB configurations:

- Auditing
- FPolicy
- Virus scanning is not performed on SMB shares with the continuously-availability parameter set to Yes.

= Continuously available share requirements and considerations for SQL Server over SMB

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You need to be aware of certain requirements and considerations when configuring continuously available shares for SQL Server over SMB configurations that support nondisruptive operations.

== Share requirements

- Volumes used to store virtual machine files must be created as NTFS security-style volumes.

To provide nondisruptive operations for application servers using continuously available SMB connections, the volume containing the share must be an NTFS volume. Moreover, it must always have been an NTFS volume. You cannot change a mixed security-style volume or UNIX security-style volume to an NTFS security-style volume and directly use it for nondisruptive operations over SMB shares. If you change a mixed security-style volume to an NTFS security style volume and intend to use it for nondisruptive operations over SMB shares, you must manually place an ACL at the top of the volume and propagate that ACL to all contained files and folders. Otherwise, virtual machine migrations or database file exports and imports where files are moved to another volume can fail if either the source or the destination volumes were initially created as mixed or UNIX security-style volumes and later changed to NTFS security style.

- Shares used by the application servers must be configured with the continuously available property set.

Application servers that connect to continuously available shares receive persistent handles that allow them to reconnect nondisruptively to SMB shares and reclaim file locks after disruptive events, such as takeover, giveback, and aggregate relocation.

- Although the volume containing the database files can contain junctions, SQL Server does not cross junctions when creating the database directory structure.
- For SnapManager for Microsoft SQL Server backup operations to succeed, you must have enough available space on the volume.

The volume on which the SQL Server database files reside must be large enough to hold the database directory structure and all contained files residing within the share.

- The following share properties must not be set on continuously available shares used by the application servers:
 - Home directory
 - Attribute caching
 - BranchCache
 - Access-based enumerations

== Share considerations

- Quotas are supported on continuously available shares.
- The following functionality is not supported for SQL Server over SMB configurations:
 - Auditing
 - FPolicy
- Virus scanning is not performed on SMB shares with the continuously-availability share property set.

= Remote VSS considerations for Hyper-V over SMB configurations

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You need to be aware of certain considerations when using Remote VSS-enabled backup solutions for Hyper-V over SMB configurations.

== General Remote VSS considerations

- A maximum of 64 shares can be configured per Microsoft application server.

The shadow copy operation fails if there are more than 64 shares in a shadow copy set. This is a Microsoft requirement.

- Only one active shadow copy set per CIFS server is allowed.

A shadow copy operation will fail if there is an ongoing shadow copy operation on the same CIFS server. This is a Microsoft requirement.

- No junctions are allowed within the directory structure on which Remote VSS creates a shadow copy.
 - In the automatic recovery case, the shadow copy creation will fail if a junction is encountered while traversing the share.
 - In the nonautomatic recovery case, the shadow copy creation does not fail, but the junction does not point to anything.

== Remote VSS considerations that apply only for shadow copies with automatic recovery

Certain limits apply only for shadow copies with automatic recovery.

- A maximum directory depth of five subdirectories is allowed for shadow copy creation.

This is the directory depth over which the shadow copy service creates a shadow copy backup set. Shadow copy creation fails if directories containing virtual machine file are nested deeper than five levels. This is intended to limit the directory traversal when cloning the share. The maximum directory depth can be changed by using a CIFS server option.

- Amount of available space on the volume must be adequate.

The available space must be at least as large as the combined space used by all files, directories, and subdirectories contained within the shares included in the shadow copy backup set.

- No links or non-regular files are allowed within the directory structure on which Remote VSS creates a

shadow copy.

The shadow copy creation fails if there are any links or non-regular files in the share to the shadow copy. The clone process does not support them.

- No NFSv4 ACLs are allowed on directories.

Although shadow copy creation retains NFSv4 ACLs on files, the NFSv4 ACLs on directories are lost.

- A maximum of 60 seconds is allowed to create a shadow copy set.

Microsoft specifications allow a maximum of 60 seconds to create the shadow copy set. If the VSS client cannot create the shadow copy set within this time, the shadow copy operation fails; therefore, this limits the number of files in a shadow copy set. The actual number of files or virtual machines that can be included in a backup set varies; that number is dependent on many factors, and must be determined for each customer environment.

= ODX copy offload requirements for SQL Server and Hyper-V over SMB

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ODX copy offload must be enabled if you want to migrate virtual machine files or export and import database files directly from source to the destination storage location without sending data through the application servers. There are certain requirements that you must understand about using ODX copy offload with SQL Server and Hyper-V over SMB solutions.

Using ODX copy offload provides a significant performance benefit. This CIFS server option is enabled by default.

- SMB 3.0 must be enabled to use ODX copy offload.
- Source volumes must be a minimum of 1.25 GB.
- Deduplication must be enabled on volumes used with copy offload.
- If you use compressed volumes, the compression type must be adaptive and only compression group size 8K is supported.

Secondary compression type is not supported

- To use ODX copy offload to migrate Hyper-V guests within and between disks, the Hyper-V servers must be configured to use SCSI disks.

The default is to configure IDE disks, but ODX copy offload does not work when guests are migrated if disks are created using IDE disks.

= Recommendations for SQL Server and Hyper-V over SMB configurations

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

To be sure that your SQL Server and Hyper-V over SMB configurations are robust

and operational, you need to be familiar with recommended best practices when configuring the solutions.

== General recommendations

- Separate application server files from general user data.

If possible, devote an entire storage virtual machine (SVM) and its storage for the application server's data.

- For best performance, do not enable SMB signing on SVMs that are used to store the application server's data.
- For best performance and improved fault tolerance, enable SMB Multichannel to provide multiple connections between ONTAP and clients in a single SMB session.
- Do not create continuously available shares on any shares other than those used in the Hyper-V or SQL Server over SMB configuration.
- Disable change notify on shares used for continuous availability.
- Do not perform a volume move at the same time as aggregate relocation (ARL) because ARL has phases that pause some operations.
- For Hyper-V over SMB solutions, use in-guest iSCSI drives when creating clustered virtual machines. Shared .VHDX files are not supported for Hyper-V over SMB in ONTAP SMB shares.

= Plan the Hyper-V or SQL Server over SMB configuration

= Complete the volume configuration worksheet

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The worksheet provides an easy way to record the values that you need when creating volumes for SQL Server and Hyper-V over SMB configurations.

For each volume, you must specify the following information:

- storage virtual machine (SVM) name

The SVM name is the same for all volumes.

- Volume name
- Aggregate name

You can create volumes on aggregates located on any node in the cluster.

- Size
- Junction path

You should keep the following in mind when creating volumes used to store application server data:

- If the root volume does not have NTFS security style, you must specify the security style as NTFS when you create the volume.

By default, volumes inherit the security style of the SVM root volume.

- Volumes should be configured with the default volume space guarantee.
- You can optionally configure the autosize space management setting.
- You should set the option that determines the Snapshot copy space reserve to 0.
- The Snapshot policy applied to the volume must be disabled.

If the SVM Snapshot policy is disabled, then you do not need to specify a Snapshot policy for the volumes. The volumes inherit the Snapshot policy for the SVM. If the Snapshot policy for the SVM is not disabled and is configured to create Snapshot copies, you must specify a Snapshot policy at the volume level, and that policy must be disabled. Shadow copy service-enabled backups and SQL Server backups manage Snapshot copy creation and deletion.

- You cannot configure load-sharing mirrors for the volumes.

Junction paths on which you plan to create shares that the application servers use should be chosen so that there are no junctioned volumes below the share entry point.

For example, if you want to store virtual machine files on four volumes named “vol1”, “vol2”, “vol3”, and “vol4”, you can create the namespace shown in the example. You can then create shares for the application servers at the following paths: /data1/vol1, /data1/vol2, /data2/vol3, and /data2/vol4.

Vserver	Volume	Active	Junction Path	Junction Path Source
vs1	data1	true	/data1	RW_volume
vs1	vol1	true	/data1/vol1	RW_volume
vs1	vol2	true	/data1/vol2	RW_volume
vs1	data2	true	/data2	RW_volume
vs1	vol3	true	/data2/vol3	RW_volume
vs1	vol4	true	/data2/vol4	RW_volume

Types of information	Values
Volume 1: Volume name, aggregate, size, junction path	
Volume 2: Volume name, aggregate, size, junction path	
Volume 3: Volume name, aggregate, size, junction path	
Volume 4: Volume name, aggregate, size, junction path	

Types of information	Values
<i>Volume 5: Volume name, aggregate, size, junction path</i>	
<i>Volume 6: Volume name, aggregate, size, junction path</i>	
<i>Additional volumes: Volume name, aggregate, size, junction path</i>	

= Complete the SMB share configuration worksheet

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Use this worksheet to record the values that you need when creating continuously available SMB shares for SQL Server and Hyper-V over SMB configurations.

== Information about SMB shares properties and configuration settings

For each share, you must specify the following information:

- storage virtual machine (SVM) name

The SVM name is the same for all shares

- Share name
- Path
- Share properties

You must configure the following two share properties:

- oplocks
- continuously-available

The following share properties must not be set:

- homediirectory attributecache
- branchcache
- access-based-enumeration

With change notify disabled, Windows 2012 Server does not refresh the Explorer window, which causes an inconsistent view of directory contents.

- Symlinks must be disabled (the value for the -symlink-properties parameter must be null [""]).

== Information about share paths

If you are using Remote VSS to back up Hyper-V files, the choice of share paths to use when making SMB connections from the Hyper-V servers to the storage locations where the virtual machine files are stored is important. Although shares can be created at any point in the namespace, paths for shares that the Hyper-V servers use should not contain junctioned volumes. Shadow copy operations cannot be performed on share paths that contain junction points.

SQL Server cannot cross junctions when creating the database directory structure. You should not create share paths for SQL server that contain junction points.

For example, given the namespace shown, if you want to store virtual machine files or database files on volumes “vol1”, “vol2”, “vol3”, and “vol4”, you should create shares for the application servers at the following paths: /data1/vol1, /data1/vol2, /data2/vol3, and /data2/vol4.

Vserver	Volume	Junction		Junction Path Source
		Active	Junction Path	
vs1	data1	true	/data1	RW_volume
vs1	vol1	true	/data1/vol1	RW_volume
vs1	vol2	true	/data1/vol2	RW_volume
vs1	data2	true	/data2	RW_volume
vs1	vol3	true	/data2/vol3	RW_volume
vs1	vol4	true	/data2/vol4	RW_volume

Although you can create shares on the /data1 and /data2 paths for administrative management, you must not configure the application servers to use those shares to store data.

== Planning worksheet

Types of information	Values
Volume 1: SMB share name and path	
Volume 2: SMB share name and path	
Volume 3: SMB share name and path	
Volume 4: SMB share name and path	
Volume 5: SMB share name and path	
Volume 6: SMB share name and path	
Volume 7: SMB share name and path	
Additional volumes: SMB share names and paths	

= Create ONTAP configurations for nondisruptive operations with Hyper-V and SQL Server over SMB

= Create ONTAP configurations for nondisruptive operations with Hyper-V and SQL Server over SMB overview

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

There are several ONTAP configuration steps you must perform to prepare for Hyper-V and SQL Server installations that provides nondisruptive operations over SMB.

Before you create the ONTAP configuration for nondisruptive operations with Hyper-V and SQL Server over SMB, the following tasks must be completed:

- Time services must be set up on the cluster.
- Networking must be set up for the SVM.
- The SVM must be created.
- Data LIF interfaces must be configured on the SVM.
- DNS must be configured on the SVM.
- Desired names services must be set up for the SVM.
- The CIFS server must be created.

[Planning the Hyper-V or SQL Server over SMB configuration](#)

[Configuration requirements and considerations](#)

= Verify that both Kerberos and NTLMv2 authentication are permitted (Hyper-V over SMB shares)

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Nondisruptive operations for Hyper-V over SMB require that the CIFS server on a data SVM and the Hyper-V server permit both Kerberos and NTLMv2 authentication. You must verify settings on both the CIFS server and the Hyper-V servers that control what authentication methods are permitted.

About this task

Kerberos authentication is required when making a continuously available share connection. Part of the Remote VSS process uses NTLMv2 authentication. Therefore, connections using both authentication methods must be supported for Hyper-V over SMB configurations.

The following settings must be configured to allow both Kerberos and NTLMv2 authentication:

- Export policies for SMB must be disabled on the storage virtual machine (SVM).

Both Kerberos and NTLMv2 authentication are always enabled on SVMs, but export policies can be used to restrict access based on authentication method.

Export policies for SMB are optional and are disabled by default. If export policies are disabled, both Kerberos and NTLMv2 authentication are allowed on a CIFS server by default.

- The domain to which the CIFS server and Hyper-V servers belong must permit both Kerberos and NTLMv2 authentication.

Kerberos authentication is enabled by default on Active Directory domains. However, NTLMv2 authentication can be disallowed, either using Security Policy settings or Group Policies.

Steps

1. Perform the following to verify that export policies are disabled on the SVM:

- a. Set the privilege level to advanced:

```
set -privilege advanced
```

- b. Verify that the `-is-exportpolicy-enabled` CIFS server option is set to `false`:

```
vserver cifs options show -vserver vserver_name -fields vserver,is-exportpolicy-enabled
```

- c. Return to the admin privilege level:

```
set -privilege admin
```

2. If export policies for SMB are not disabled, disable them:

```
vserver cifs options modify -vserver vserver_name -is-exportpolicy-enabled false
```

3. Verify that both NTLMv2 and Kerberos authentication are allowed in the domain.

For information about determining what authentication methods are allowed in the domain, see the Microsoft TechNet Library.

4. If the domain does not permit NTLMv2 authentication, enable NTLMv2 authentication by using one of the methods described in Microsoft documentation.

Example

The following commands verify that export policies for SMB are disabled on SVM vs1:

```
cluster1::> set -privilege advanced
Warning: These advanced commands are potentially dangerous; use them
only when directed to do so by technical support personnel.
Do you wish to continue? (y or n): y

cluster1::*> vserver cifs options show -vserver vs1 -fields vserver,is-exportpolicy-enabled

vserver  is-exportpolicy-enabled
-----
vs1      false

cluster1::*> set -privilege admin
```

```
= Verify that domain accounts map to the default UNIX user  
:icons: font  
:relative_path: ./smb-hyper-v-sql/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/./media/
```

Hyper-V and SQL Server use domain accounts to create SMB connections to continuously available shares. To successfully create the connection, the computer account must successfully map to a UNIX user. The most convenient way to accomplish this is to map the computer account to the default UNIX user.

About this task

Hyper-V and SQL Server use the domain computer accounts to create SMB connections. In addition, SQL Server uses a domain user account as the service account that also makes SMB connections.

When you create a storage virtual machine (SVM), ONTAP automatically creates the default user named “pcuser” (with a UID of 65534) and the group named “pcuser” (with a GID of 65534), and adds the default user to the “pcuser” group. If you are configuring a Hyper-V over SMB solution on anSVM that existed prior to upgrading the cluster to Data ONTAP 8.2, the default user and group might not exist. If they do not, you must create them before configuring the CIFS server’s default UNIX user.

Steps

1. Determine whether there is a default UNIX user:

```
vserver cifs options show -vserver vserver_name
```

2. If the default user option is not set, determine whether there is a UNIX user that can be designated as the default UNIX user:

```
vserver services unix-user show -vserver vserver_name
```

3. If the default user option is not set and there is not a UNIX user that can be designated as the default UNIX user, create the default UNIX user and the default group, and add the default user to the group.

Generally, the default user is given the user name “pcuser” and must be assigned the UID of 65534. The default group is generally given the group name “pcuser”. The GID assigned to the group must be 65534.

- a. Create the default group:

```
+
```

```
vserver services unix-group create -vserver vserver_name -name pcuser  
-id 65534
```

- b. Create the default user and add the default user to the default group:

```
+
```

```
vserver services unix-user create -vserver vserver_name -user pcuser -id  
65534 -primary-gid 65534
```

- c. Verify that the default user and default group are configured correctly:

```
+
```

```
vserver services unix-user show -vserver vserver_name
```

```
+
```

```
vserver services unix-group show -vserver vserver_name -members
```

4. If the CIFS server's default user is not configured, perform the following:

- Configure the default user:

```
vserver cifs options modify -vserver *vserver_name -default-unix-user  
pcuser*
```

- Verify that the default UNIX user is configured correctly:

```
vserver cifs options show -vserver vserver_name
```

5. To verify that the application server's computer account correctly maps to the default user, map a drive to a share residing on the SVM and confirm the Windows user to UNIX user mapping by using the vserver cifs session show command.

For more information about using this command, see the man pages.

Example

The following commands determine that the CIFS server's default user is not set, but determines that the "pcuser" user and "pcuser" group exist. The "pcuser" user is assigned as the CIFS server's default user on SVM vs1.

```
cluster1::> vserver cifs options show
```

```
Vserver: vs1
```

```

```

= Verify that the security style of the SVM root volume is set to NTFS

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

To ensure that nondisruptive operations for Hyper-V and SQL Server over SMB are successful, volumes must be created with NTFS security style. Since the root volume's security style is applied by default to volumes created on the storage virtual machine (SVM), the security style of the root volume should be set to NTFS.

About this task

- You can specify the root volume security style at the time you create the SVM.
- If the SVM is not created with the root volume set to NTFS security style, you can change the security style later by using the `volume modify` command.

Steps

1. Determine the current security style of the SVM root volume:

```
volume show -vserver vserver_name -fields vserver,volume,security-style
```

2. If the root volume is not an NTFS security-style volume, change the security style to NTFS:

```
volume modify -vserver vserver_name -volume root_volume_name -security
-style ntfs
```

3. Verify that the SVM root volume is set to NTFS security style:

```
volume show -vserver vserver_name -fields vserver,volume,security-style
```

Example

The following commands verify that the root volume security style is NTFS on SVM vs1:

```
cluster1::> volume show -vserver vs1 -fields vserver,volume,security-
style
vserver    volume      security-style
-----
vs1        vs1_root    unix

cluster1::> volume modify -vserver vs1 -volume vs1_root -security-style
ntfs

cluster1::> volume show -vserver vs1 -fields vserver,volume,security-
style
vserver    volume      security-style
-----
vs1        vs1_root    ntfs
```

= Verify that required CIFS server options are configured

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You must verify that the required CIFS server options are enabled and configured according to requirements for nondisruptive operations for Hyper-V and SQL Server over SMB.

About this task

- SMB 2.x and SMB 3.0 must be enabled.
- ODX copy offload must be enabled to use performance enhancing copy offload.
- VSS Shadow Copy services must be enabled if the Hyper-V over SMB solution uses Remote VSS-enabled backup services (Hyper-V only).

Steps

1. Verify that the required CIFS server options are enabled on the storage virtual machine (SVM):

- a. Set the privilege level to advanced:

```
set -privilege advanced
```

- b. Enter the following command:

```
vserver cifs options show -vserver vserver_name
```

The following options should be set to true:

- -smb2-enabled
- -smb3-enabled
- -copy-offload-enabled
- -shadowcopy-enabled (Hyper-V only)

2. If any of the options are not set to true, perform the following:
 - a. Set them to true by using the vserver cifs options modify command.
 - b. Verify that the options are set to true by using the vserver cifs options show command.
3. Return to the admin privilege level:

```
set -privilege admin
```

Example

The following commands verify that the required options for the Hyper-V over SMB configuration are enabled on SVM vs1. In the example, ODX copy offload must be enabled to meet the option requirements.

```
cluster1::> set -privilege advanced
Warning: These advanced commands are potentially dangerous; use them
only when directed to do so by technical support personnel.
Do you wish to continue? (y or n): y

cluster1::*> vserver cifs options show -vserver vs1 -fields smb2-
enabled,smb3-enabled,copy-offload-enabled,shadowcopy-enabled
vserver smb2-enabled smb3-enabled copy-offload-enabled shadowcopy-

-----
-----
vs1      true        true        false        true

cluster-1::*> vserver cifs options modify -vserver vs1 -copy-offload-
-enabled true

cluster-1::*> vserver cifs options show -vserver vs1 -fields copy-
offload-enabled
vserver  copy-offload-enabled
-----
vs1      true

cluster1::*> set -privilege admin
```

= Configure SMB Multichannel for performance and redundancy
 :icons: font
 :relative_path: ./smb-hyper-v-sql/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

Beginning with ONTAP 9.4, you can configure SMB Multichannel to provide multiple connections between ONTAP and clients in a single SMB session. Doing so improves throughput and fault tolerance for Hyper-V and SQL server over SMB configurations.

What you'll need

You can use SMB Multichannel functionality only when clients negotiate at SMB 3.0 or later versions. SMB 3.0 and later is enabled on the ONTAP SMB server by default.

About this task

SMB clients automatically detect and use multiple network connections if a proper configuration is identified on the ONTAP cluster.

The number of simultaneous connections in an SMB session depends on the NICs you have deployed:

- **1G NICs on client and ONTAP cluster**

The client establishes one connection per NIC and binds the session to all connections.

- **10G and larger capacity NICs on client and ONTAP cluster**

The client establishes up to four connections per NIC and binds the session to all connections. The client can establish connections on multiple 10G and larger capacity NICs.

You can also modify the following parameters (advanced privilege):

- **-max-connections-per-session**

The maximum number of connections allowed per Multichannel session. The default is 32 connections.

If you want to enable more connections than the default, you must make comparable adjustments to the client configuration, which also has a default of 32 connections.

- **-max-lifs-per-session**

The maximum number of network interfaces advertised per Multichannel session. The default is 256 network interfaces.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Enable SMB Multichannel on the SMB server:

```
vserver cifs options modify -vserver vserver_name -is-multichannel-enabled true
```

3. Verify that ONTAP is reporting SMB Multichannel sessions:

```
vserver cifs session show options
```

4. Return to the admin privilege level:

```
set -privilege admin
```

Example

The following example displays information about all SMB sessions, showing multiple connections for a single session:

```
cluster1::> vserver cifs session show
Node:      node1
Vserver:   vs1
Connection Session          Open
Idle
IDs       ID     Workstation      Windows User      Files

          Protocol Version: SMB3
          Continuously Available: No
          Is Session Signed: false
          NetBIOS Name: -

```

= Create NTFS data volumes

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You must create NTFS data volumes on the storage virtual machine (SVM) before you can configure continuously available shares for use with Hyper-V or SQL Server over SMB application servers. Use the volume configuration worksheet to create your data volumes.

About this task

There are optional parameters that you can use to customize a data volume. For more information about customizing volumes, see the xref:./smb-admin/[Logical storage management](#).

As you create your data volumes, you should not create junction points within a volume that contains the following:

- Hyper-V files for which ONTAP makes shadow copies
- SQL Server database files that are backed up using SQL Server

 If you inadvertently create a volume that uses mixed or UNIX security style, you cannot change the volume to an NTFS security style volume and then directly use it to create continuously available shares for nondisruptive operations. Nondisruptive operations for Hyper-V and SQL Server over SMB do not work correctly unless the volumes used in the configuration are created as NTFS security-style volumes. You must either delete the volume and re-create the volume with NTFS security style, or you can map the volume on a Windows host and apply an ACL at the top of the volume and propagate the ACL to all files and folders in the volume.

Steps

1. Create the data volume by entering the appropriate command:

If you want to create a volume in an SVM where the root volume security style is...	Enter the command...
NTFS	<code>volume create -vserver vserver_name -volume volume_name -aggregate aggregate_name -size integer[KB MB GB TB PB] -junction-path path</code>
Not NTFS	<code>volume create -vserver vserver_name -volume volume_name -aggregate aggregate_name -size integer[KB MB GB TB PB] -security-style ntfs -junction-path path</code>

2. Verify that the volume configuration is correct:

```
volume show -vserver vserver_name -volume volume_name
```

= Create continuously available SMB shares
 :icons: font
 :relative_path: ./smb-hyper-v-sql/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

After you create your data volumes, you can create the continuously available shares that the application servers use to access Hyper-V virtual machine and configuration files and SQL Server database files. You should use the share configuration worksheet as you create the SMB shares.

Steps

1. Display information about the existing data volumes and their junction paths:

```
volume show -vserver vserver_name -junction
```

2. Create a continuously available SMB share:

```
vserver cifs share create -vserver vserver_name -share-name share_name -path path -share-properties oplocks,continuously-available -symlink "" [-comment text]
```

- You can optionally add a comment to the share configuration.
 - By default, the offline files share property is configured on the share and is set to manual.
 - ONTAP creates the share with the Windows default share permission of Everyone / Full Control.
3. Repeat the previous step for all shares in the share configuration worksheet.
 4. Verify that your configuration is correct by using the vserver cifs share show command.
 5. Configure NTFS file permissions on the continuously available shares by mapping a drive to each share, and configuring file permissions by using the **Windows Properties** window.

Example

The following commands create a continuously available share named “data2” on storage virtual machine (SVM, formerly known as Vserver) vs1. Symlinks are disabled by setting the –symlink parameter to “”:

```
cluster1::> volume show -vserver vs1 -junction
              Junction          Junction
Vserver   Volume     Active   Junction Path      Path Source
-----  -----
vs1       data       true    /data           RW_volume
vs1       data1      true    /data/data1     RW_volume
vs1       data2      true    /data/data2     RW_volume
vs1       vs1_root   -       /               -
```

```
cluster1::> vserver cifs share create -vserver vs1 -share-name data2
-path /data/data2 -share-properties oplocks,continuously-available
-symlink ""
```

```
cluster1::> vserver cifs share show -vserver vs1 -share-name data2

          Vserver: vs1
          Share: data2
CIFS Server NetBIOS Name: VS1
          Path: /data/data2
Share Properties: oplocks
                  continuously-available
Symlink Properties: -
File Mode Creation Mask: -
Directory Mode Creation Mask: -
Share Comment: -
          Share ACL: Everyone / Full Control
File Attribute Cache Lifetime: -
          Volume Name: -
Offline Files: manual
Vscan File-Operations Profile: standard
```

= Add the SeSecurityPrivilege privilege to the user account (for SQL Server of SMB shares)

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The domain user account used for installing the SQL server must be assigned the “SeSecurityPrivilege” privilege to perform certain actions on the CIFS server that require privileges not assigned by default to domain users.

What you'll need

The domain account used for installing the SQL Server must already exist.

About this task

When adding the privilege to the SQL Server installer's account, ONTAP might validate the account by contacting the domain controller. The command might fail if ONTAP cannot contact the domain controller.

Steps

1. Add the “SeSecurityPrivilege” privilege:

```
vserver cifs users-and-groups privilege add-privilege -vserver vserver_name  
-user-or-group-name account_name -privileges SeSecurityPrivilege
```

The value for the –user-or-group-name parameter is the name of the domain user account used for installing the SQL Server.

2. Verify that the privilege is applied to the account:

```
vserver cifs users-and-groups privilege show -vserver vserver_name -user-  
or-group-name account_name
```

Example

The following command adds the “SeSecurityPrivilege” privilege to the SQL Server installer's account in the EXAMPLE domain for storage virtual machine (SVM) vs1:

```
cluster1::> vserver cifs users-and-groups privilege add-privilege  
-vserver vs1 -user-or-group-name EXAMPLE\SQLInstaller -privileges  
SeSecurityPrivilege
```

```
cluster1::> vserver cifs users-and-groups privilege show -vserver vs1  
Vserver      User or Group Name          Privileges  
-----  
vs1          EXAMPLE\SQLInstaller        SeSecurityPrivilege
```

= Configure the VSS shadow copy directory depth (for Hyper-V over SMB shares)

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Optionally, you can configure the maximum depth of directories within SMB shares on

which to create shadow copies. This parameter is useful if you want to manually control the maximum level of subdirectories on which ONTAP should create shadow copies.

What you'll need

The VSS shadow copy feature must be enabled.

About this task

The default is to create shadow copies for a maximum of five subdirectories. If the value is set to 0, ONTAP creates shadow copies for all subdirectories.

Although you can specify that the shadow copy set directory depth include more than five subdirectories or all subdirectories, there is a Microsoft requirement that shadow copy set creation must be completed within 60 seconds. Shadow copy set creation fails if it cannot be completed within this time. The shadow copy directory depth you choose must not cause the creation time to exceed the time limit.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Set the VSS shadow copy directory depth to the desired level:

```
vserver cifs options modify -vserver vserver_name -shadowcopy-dir-depth integer
```

```
vserver cifs options modify -vserver vs1 -shadowcopy-dir-depth 6
```

3. Return to the admin privilege level:

```
set -privilege admin
```

= Manage Hyper-V and SQL Server over SMB configurations

= Configure existing shares for continuous availability

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can modify existing shares to become continuously available shares that the Hyper-V and SQL Server application servers use to nondisruptively access Hyper-V virtual machine and configuration files and SQL Server database files.

About this task

You cannot use an existing share as a continuously available share for nondisruptive operations with application servers over SMB if the share has the following characteristics:

- If the homedirectory share property is set on that share
- If the share contains enabled symlinks or widelinks

- If the share contains junctioned volumes below the root of the share

You must verify that the two following share parameters are set correctly:

- The `-offline-files` parameter is set to either `manual` (the default) or `none`.
- Symlinks must be disabled.

The following share properties must be configured:

- `continuously-available`
- `oplocks`

The following share properties must not be set. If they are present in the list of current share properties, they need to be removed from the continuously available share:

- `attribute-cache`
- `branch-cache`
- `access-based-enumeration`

Steps

1. Display the current share parameter settings and the current list of configured share properties:

```
vserver cifs share show -vserver vserver_name -share-name share_name
```

2. If necessary, modify the share parameters to disable symlinks and set offline files to manual by using the `vserver cifs share properties modify` command.

You can disable symlinks by setting the value of the `-symlink` parameter to `" "`.

- You can disable symlinks by setting the value of the `-symlink` parameter to `" "`.
- You can set the `-offline-files` parameter to the correct setting by specifying `manual`.

3. Add the `continuously-available` share property, and, if needed, the `oplocks` share property:

```
vserver cifs share properties add -vserver vserver_name -share-name share_name -share-properties continuously-available[,oplock]
```

If the `oplocks` share property is not already set, you must add it along with the `continuously-available` share property.

4. Remove any share properties that are not supported on continuously available shares:

```
vserver cifs share properties remove -vserver vserver_name -share-name share_name -share-properties properties[,...]
```

You can remove one or more share properties by specifying the share properties with a comma-delimited list.

5. Verify that the `-symlink` and `-offline-files` parameters are set correctly:

```
vserver cifs share show -vserver vserver_name -share-name share_name
```

```
-fields symlink-properties,offline-files
```

6. Verify that the list of configured share properties is correct:

```
vserver cifs shares properties show -vserver vserver_name -share-name  
share_name
```

Examples

The following example shows how to configure an existing share named “share1” on storage virtual machine (SVM) vs1 for NDOs with an application server over SMB:

- Symlinks are disabled on the share by setting the `-symlink` parameter to “”.
- The `-offline-file` parameter is modified and set to `manual`.
- The `continuously-available` share property is added to the share.
- The `oplocks` share property is already in the list of share properties; therefore, it does not need to be added.
- The `attributecache` share property is removed from the share.
- The `browsable` share property is optional for a continuously available share used for NDOs with application servers over SMB and is retained as one of the share properties.

```

cluster1::> vserver cifs share show -vserver vs1 -share-name share1

          Vserver: vs1
          Share: share1
  CIFS Server NetBIOS Name: vs1
          Path: /data
  Share Properties: oplocks
                  browsable
                  attributecache
  Symlink Properties: enable
  File Mode Creation Mask: -
  Directory Mode Creation Mask: -
  Share Comment: -
          Share ACL: Everyone / Full Control
File Attribute Cache Lifetime: 10s
          Volume Name: data
          Offline Files: documents
Vscan File-Operations Profile: standard

cluster1::> vserver cifs share modify -vserver vs1 -share-name share1
-offline-file manual -symlink ""

cluster1::> vserver cifs share properties add -vserver vs1 -share-name
share1 -share-properties continuously-available

cluster1::> vserver cifs share properties remove -vserver vs1 -share
-name share1 -share-properties attributecache

cluster1::> vserver cifs share show -vserver vs1 -share-name share1
-fields symlink-properties,offline-files
vserver  share-name symlink-properties offline-files
-----
vs1      share1    -                      manual

cluster1::> vserver cifs share properties show -vserver vs1 -share-name
share1

          Vserver: vs1
          Share: share1
  Share Properties: oplocks
                  browsable
                  continuously-available

```

= Enable or disable VSS shadow copies for Hyper-V over SMB backups
:icons: font

```
:relative_path: ./smb-hyper-v-sql/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

If you use a VSS-aware backup application to back up Hyper-V virtual machine files stored on SMB shares, VSS shadow copy must be enabled. You can disable the VSS shadow copy if you do not use VSS-aware backup applications. The default is to enable the VSS shadow copy.

About this task

You can enable or disable VSS shadow copies at any time.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Perform one of the following actions:

If you want VSS shadow copies to be...	Enter the command...
Enabled	<pre>vserver cifs options modify -vserver vserver_name -shadowcopy-enabled true</pre>
Disabled	<pre>vserver cifs options modify -vserver vserver_name -shadowcopy-enabled false</pre>

3. Return to the admin privilege level:

```
set -privilege admin
```

Example

The following commands enable VSS shadow copies on SVM vs1:

```
cluster1::> set -privilege advanced
Warning: These advanced commands are potentially dangerous; use them
only when directed to do so by technical support personnel.
Do you wish to continue? (y or n): y

cluster1::*> vserver cifs options modify -vserver vs1 -shadowcopy
-enabled true

cluster1::*> set -privilege admin
```

= Use statistics to monitor Hyper-V and SQL Server over SMB activity

= Determine which statistics objects and counters are available

```
:icons: font
:relative_path: ./smb-hyper-v-sql/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

Before you can obtain information about CIFS, SMB, auditing, and BranchCache hash statistics and monitor performance, you must know which objects and counters are available from which you can obtain data.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Perform one of the following actions:

If you want to determine...	Enter...
Which objects are available	statistics catalog object show
Specific objects that are available	statistics catalog object show object object_name
Which counters are available	statistics catalog counter show object object_name

See the man pages for more information about which objects and counters are available.

3. Return to the admin privilege level:

```
set -privilege admin
```

Examples

The following command displays descriptions of selected statistic objects related to CIFS and SMB access in the cluster as seen at the advanced privilege level:

```

cluster1::> set -privilege advanced

Warning: These advanced commands are potentially dangerous; use them
only when directed to do so by support personnel.
Do you want to continue? {y|n}: y

cluster1::*> statistics catalog object show -object audit
    audit_ng                                CM object for exporting audit_ng
performance counters

cluster1::*> statistics catalog object show -object cifs
    cifs                                    The CIFS object reports activity of the
                                                Common Internet File System protocol
                                                ...
cluster1::*> statistics catalog object show -object nblade_cifs
    nblade_cifs                            The Common Internet File System (CIFS)
                                                protocol is an implementation of the
Server
                                                ...
cluster1::*> statistics catalog object show -object smb1
    smb1                                    These counters report activity from the
SMB
                                                revision of the protocol. For
information
                                                ...
cluster1::*> statistics catalog object show -object smb2
    smb2                                    These counters report activity from the
                                                SMB2/SMB3 revision of the protocol. For
                                                ...
cluster1::*> statistics catalog object show -object hashd
    hashd                                  The hashd object provides counters to
measure
                                                the performance of the BranchCache hash
daemon.
cluster1::*> set -privilege admin

```

The following command displays information about some of the counters for the `cifs` object as seen at the advanced privilege level:

This example does not display all of the available counters for the `cifs` object; output is truncated.

```

cluster1::> set -privilege advanced

Warning: These advanced commands are potentially dangerous; use them
only when directed to do so by support personnel.
Do you want to continue? {y|n}: y

cluster1::*> statistics catalog counter show -object cifs

      cifs_read_recv_ops 0
      cifs_read_recv_size 0B
      cifs_read_size    0B
      cifs_write_ops     0
      cifs_write_recv_ops 0
      cifs_write_recv_size 0B
      cifs_write_size    0B
      instance_name      vserver_1:10.72.205.179
      instance_uuid       2:10.72.205.179
      local_ops          0
      mount_ops          0

      [...]

```

= Display SMB statistics
 :icons: font
 :relative_path: ./smb-hyper-v-sql/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can display various SMB statistics to monitor performance and diagnose issues.

Steps

1. Use the `statistics start` and optional `statistics stop` commands to collect a data sample.

For more information about these commands, see the [System Administration Reference](#).

2. Perform one of the following actions:

If you want to display statistics for...	Enter the following command...
All versions of SMB	<code>statistics show -object cifs</code>
SMB 1.0	<code>statistics show -object smb1</code>
SMB 2.x and SMB 3.0	<code>statistics show -object smb2</code>
CIFS subsystem of the node	<code>statistics show -object nblade_cifs</code>

See the man page for more information.

= Verify that the configuration is capable of nondisruptive operations

= Use health monitoring to determine whether nondisruptive operation status is healthy

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

Health monitoring provides information about system health status across the cluster. The health monitor monitors Hyper-V and SQL Server over SMB configurations to ensure nondisruptive operations (NDOs) for the application servers. If the status is degraded, you can view details about the problem, including the probable cause and recommended recovery actions.

There are several health monitors. ONTAP monitors both overall system health and health for individual health monitors. The node connectivity health monitor contains the CIFS-NDO subsystem. The monitor has a set of health policies that trigger alerts if certain physical conditions can lead to disruption, and if a disruptive condition exists, generates alerts and provides information about corrective actions. For NDO over SMB configurations, alerts are generated for the two following conditions:

Alert ID	Severity	Condition
HaNotReadyCifsNdo_Alert	Major	One or more files hosted by a volume in an aggregate on the node have been opened through a continuously available SMB share with the promise of persistence in the event of a failure; however, the HA relationship with the partner is either not configured or not healthy.
NoStandbyLifCifsNdo_Alert	Minor	The storage virtual machine (SVM) is actively serving data over SMB through a node, and there are SMB files opened persistently over continuously available shares; however, its partner node is not exposing any active data LIFs for the SVM.

= Display nondisruptive operation status by using system health monitoring

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can use the `system health` commands to display information about the overall system health of the cluster and the health of the CIFS-NDO subsystem, to respond to alerts, to configure future alerts, and to display information about how health monitoring is configured.

Steps

1. Monitor health status by performing the appropriate action:

If you want to display...	Enter the command...
The health status of the system, which reflects the overall status of individual health monitors	<code>system health status show</code>
Information about the health status of the CIFS-NDO subsystem	<code>system health subsystem show -subsystem CIFS-NDO -instance</code>

2. Display information about how CIFS-NDO alert monitoring is configured by performing the appropriate actions:

If you want to display information about...	Enter the command...
The configuration and status of the health monitor for the CIFS-NDO subsystem, such as nodes monitored, initialization state, and status	system health config show -subsystem CIFS-NDO
The CIFS-NDO alerts that a health monitor can potentially generate	system health alert definition show -subsystem CIFS-NDO
CIFS-NDO health monitor policies, which determine when alerts are raised	system health policy definition show -monitor node-connect

Use the **-instance** parameter to display detailed information.

Examples

The following output shows information about the overall health status of the cluster and the CIFS-NDO subsystem:

```
cluster1::> system health status show
Status
-----
ok

cluster1::> system health subsystem show -instance -subsystem CIFS-NDO

        Subsystem: CIFS-NDO
        Health: ok
        Initialization State: initialized
Number of Outstanding Alerts: 0
Number of Suppressed Alerts: 0
        Node: node2
Subsystem Refresh Interval: 5m
```

The following output shows detailed information about the configuration and status of the health monitor of the CIFS-NDO subsystem:

```

cluster1::> system health config show -subsystem CIFS-NDO -instance

          Node: node1
          Monitor: node-connect
          Subsystem: SAS-connect, HA-health, CIFS-NDO
          Health: ok
          Monitor Version: 2.0
          Policy File Version: 1.0
          Context: node_context
          Aggregator: system-connect
          Resource: SasAdapter, SasDisk, SasShelf,
HaNodePair,
                           HaICMailbox, CifsNdoNode,
CifsNdoNodeVserver
Subsystem Initialization Status: initialized
Subordinate Policy Versions: 1.0 SAS, 1.0 SAS multiple adapters,
1.0, 1.0

          Node: node2

= Verify the continuously available SMB share configuration

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

To support nondisruptive operations, Hyper-V and SQL Server SMB shares must be configured as continuously available shares. Additionally, there are certain other share settings that you must check. You should verify that the shares are properly configured to provide seamless nondisruptive operations for the application servers if there are planned or unplanned disruptive events.

About this task

You must verify that the two following share parameters are set correctly:

- The `-offline-files` parameter is set to either `manual` (the default) or `none`.
- Symlinks must be disabled.

For proper nondisruptive operations, the following share properties must be set:

- `continuously-available`
- `oplocks`

The following share properties must not be set:

- `homedirectory`
- `attribute-cache`
- `branchcache`
- `access-based-enumeration`

Steps

1. Verify that the offline files are set to `manual` or `disabled` and that symlinks are disabled:

```
vserver cifs shares show -vserver vserver_name
```

2. Verify that the SMB shares are configured for continuous availability:

```
vserver cifs shares properties show -vserver vserver_name
```

Examples

The following example displays the share setting for a share named “share1” on storage virtual machine (SVM, formerly known as Vserver) `vs1`. Offline files are set to `manual` and symlinks are disabled (designated by a hyphen in the `Symlink Properties` field output):

```

cluster1::> vserver cifs share show -vserver vs1 -share-name share1
          Vserver: vs1
          Share: share1
          CIFS Server NetBIOS Name: VS1
          Path: /data/share1
          Share Properties: oplocks
                           continuously-available
          Symlink Properties: -
          File Mode Creation Mask: -
          Directory Mode Creation Mask: -
          Share Comment: -
          Share ACL: Everyone / Full Control
          File Attribute Cache Lifetime: -
          Volume Name: -
          Offline Files: manual
          Vscan File-Operations Profile: standard

```

The following example displays the share properties for a share named “share1” on SVM vs1:

```

cluster1::> vserver cifs share properties show -vserver vs1 -share-name
share1
Vserver      Share      Properties
-----      -----      -----
vs1          share1    oplocks
                           continuously-available

```

= Verify LIF status

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Even if you configure storage virtual machines (SVMs) with Hyper-V and SQL Server over SMB configurations to have LIFs on each node in a cluster, during day-to-day operations, some LIFs might move to ports on another node. You must verify LIF status and take any necessary corrective actions.

About this task

To provide seamless, nondisruptive operation support, each node in a cluster must have at least one LIF for the SVM, and all the LIFs must be associated with a home port. If some of the configured LIFs are not currently associated with their home port, you must fix any port issues and then revert the LIFs to their home port.

Steps

1. Display information about configured LIFs for the SVM:

```
network interface show -vserver vserver_name
```

In this example, "lif1" is not located on the home port.

```
network interface show -vserver vs1
```

Current Is		Logical	Status	Network	Current	
Vserver	Home	Interface	Admin/Oper	Address/Mask	Node	Port
<hr/>						
<hr/>						
vs1	false	lif1	up/up	10.0.0.128/24	node2	e0d
true		lif2	up/up	10.0.0.129/24	node2	e0d

2. If some of the LIFs are not on their home ports, perform the following steps:

a. For each LIF, determine what the LIF's home port is:

```
network interface show -vserver vserver_name -lif lif_name -fields home-node,home-port
```

```
network interface show -vserver vs1 -lif lif1 -fields home-node,home-port
```

vserver	lif	home-node	home-port
<hr/>			
vs1	lif1	node1	e0d

b. For each LIF, determine whether the LIF's home port is up:

```
network port show -node node_name -port port -fields port,link
```

```
network port show -node node1 -port e0d -fields port,link
```

node	port	link
<hr/>		
node1	e0d	up

In this example, "lif1" should be migrated back to its home port, node1:e0d.

3. If any of the home port network interfaces to which the LIFs should be associated are not in the **up** state, resolve the problem so that these interfaces are up.
4. If needed, revert the LIFs to their home ports:

```
network interface revert -vserver vserver_name -lif lif_name
```

```
network interface revert -vserver vs1 -lif lif1
```

5. Verify that each node in the cluster has an active LIF for the SVM:

```
network interface show -vserver vserver_name
```

```
network interface show -vserver vs1
```

Current Is	Logical	Status	Network	Current	
Vserver	Interface	Admin/Oper	Address/Mask	Node	Port
Home					
<hr/>					
vs1					
true	lif1	up/up	10.0.0.128/24	node1	e0d
true	lif2	up/up	10.0.0.129/24	node2	e0d

= Determine whether SMB sessions are continuously available

= Display SMB session information

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can display information about established SMB sessions, including the SMB connection and session ID and the IP address of the workstation using the session. You can display information about the session's SMB protocol version and continuously available protection level, which helps you to identify whether the session supports nondisruptive operations.

About this task

You can display information for all of the sessions on your SVM in summary form. However, in many cases, the amount of output that is returned is large. You can customize what information is displayed in the output by specifying optional parameters:

- You can use the optional `-fields` parameter to display output about the fields you choose.

You can enter `-fields ?` to determine what fields you can use.

- You can use the `-instance` parameter to display detailed information about established SMB sessions.
- You can use the `-fields` parameter or the `-instance` parameter either alone or in combination with other optional parameters.

Steps

1. Perform one of the following actions:

If you want to display SMB session information...	Enter the following command...
For all sessions on the SVM in summary form	<code>vserver cifs session show -vserver vserver_name</code>
On a specified connection ID	<code>vserver cifs session show -vserver vserver_name -connection-id integer</code>
From a specified workstation IP address	<code>vserver cifs session show -vserver vserver_name -address workstation_IP_address</code>
On a specified LIF IP address	<code>vserver cifs session show -vserver vserver_name -lif -address LIF_IP_address</code>
On a specified node	<code>vserver cifs session show -vserver vserver_name -node {node_name local}</code>
From a specified Windows user	<code>vserver cifs session show -vserver vserver_name -windows-user user_name</code> The format for <code>user_name</code> is [domain]\user.
With a specified authentication mechanism	<code>vserver cifs session show -vserver vserver_name -auth -mechanism authentication_mechanism</code> The value for <code>-auth-mechanism</code> can be one of the following: <ul style="list-style-type: none">• NTLMv1• NTLMv2• Kerberos• Anonymous

If you want to display SMB session information...	Enter the following command...
With a specified protocol version	<pre>vserver cifs session show -vserver vserver_name -protocol-version protocol_version</pre> <p>The value for <code>-protocol-version</code> can be one of the following:</p> <ul style="list-style-type: none"> • SMB1 • SMB2 • SMB2_1 • SMB3 • SMB3_1 <p> Continuously available protection and SMB Multichannel are available only on SMB 3.0 and later sessions. To view their status on all qualifying sessions, you should specify this parameter with the value set to SMB3 or later.</p>
With a specified level of continuously available protection	<pre>vserver cifs session show -vserver vserver_name -continuously-available continuously_available_protection_level</pre> <p>The value for <code>-continuously-available</code> can be one of the following:</p> <ul style="list-style-type: none"> • No • Yes • Partial <p> If the continuously available status is <code>Partial</code>, this means that the session contains at least one open continuously available file, but the session has some files that are not open with continuously available protection. You can use the <code>vserver cifs sessions file show</code> command to determine which files on the established session are not open with continuously available protection.</p>
With a specified SMB signing session status	<pre>vserver cifs session show -vserver vserver_name -is -session-signed {true false}</pre>

Examples

The following command displays session information for the sessions on SVM vs1 established from a workstation with IP address 10.1.1.1:

```

cluster1::> vserver cifs session show -address 10.1.1.1
Node:      node1
Vserver:   vs1
Connection Session
ID          ID      Workstation      Windows User      Open      Idle
-----  -----  -----
3151272279,
3151272280,
3151272281  1        10.1.1.1        DOMAIN\joe       2           23s

```

The following command displays detailed session information for sessions with continuously available protection on SVM vs1. The connection was made by using the domain account.

```

cluster1::> vserver cifs session show -instance -continuously-available
Yes

          Node: node1
          Vserver: vs1
          Session ID: 1
          Connection ID: 3151274158
Incoming Data LIF IP Address: 10.2.1.1
          Workstation IP address: 10.1.1.2
          Authentication Mechanism: Kerberos
          Windows User: DOMAIN\SERVER1$
          UNIX User: pcuser
          Open Shares: 1
          Open Files: 1
          Open Other: 0
          Connected Time: 10m 43s
          Idle Time: 1m 19s
          Protocol Version: SMB3
Continuously Available: Yes
          Is Session Signed: false
          User Authenticated as: domain-user
          NetBIOS Name: -
SMB Encryption Status: Unencrypted

```

The following command displays session information on a session using SMB 3.0 and SMB Multichannel on SVM vs1. In the example, the user connected to this share from an SMB 3.0 capable client by using the LIF IP address; therefore, the authentication mechanism defaulted to NTLMv2. The connection must be made by using Kerberos authentication to connect with continuously available protection.

```
cluster1::> vserver cifs session show -instance -protocol-version SMB3

          Node: node1
          Vserver: vs1
          Session ID: 1
          **Connection IDs: 3151272607,31512726078,3151272609
          Connection Count: 3**
Incoming Data LIF IP Address: 10.2.1.2
          Workstation IP address: 10.1.1.3
          Authentication Mechanism: NTLMv2
          Windows User: DOMAIN\administrator
          UNIX User: pcuser
          Open Shares: 1
          Open Files: 0
          Open Other: 0
          Connected Time: 6m 22s
          Idle Time: 5m 42s
          Protocol Version: SMB3
Continuously Available: No
          Is Session Signed: false
          User Authenticated as: domain-user
          NetBIOS Name: -
          SMB Encryption Status: Unencrypted
```

= Display information about open SMB files

:icons: font

:relative_path: ./smb-hyper-v-sql/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..../media/

You can display information about open SMB files, including the SMB connection and session ID, the hosting volume, the share name, and the share path. You can also display information about the continuously available protection level of a file, which is helpful in determining whether an open file is in a state that supports nondisruptive operations.

About this task

You can display information about open files on an established SMB session. The displayed information is useful when you need to determine SMB session information for particular files within an SMB session.

For example, if you have an SMB session where some of the open files are open with continuously available protection and some are not open with continuously available protection (the value for the `-continuously-available` field in `vserver cifs session show` command output is `Partial`), you can determine which files are not continuously available by using this command.

You can display information for all open files on established SMB sessions on storage virtual machines (SVMs) in summary form by using the `vserver cifs session file show` command without any optional parameters.

However, in many cases, the amount of output returned is large. You can customize what information is displayed in the output by specifying optional parameters. This can be helpful when you want to view information for only a small subset of open files.

- You can use the optional `-fields` parameter to display output on the fields you choose.
You can use this parameter either alone or in combination with other optional parameters.
- You can use the `-instance` parameter to display detailed information about open SMB files.
You can use this parameter either alone or in combination with other optional parameters.

Steps

1. Perform one of the following actions:

If you want to display open SMB files...	Enter the following command...
On the SVM in summary form	<code>vserver cifs session file show -vserver vserver_name</code>
On a specified node	<code>vserver cifs session file show -vserver vserver_name -node {node_name local}</code>
On a specified file ID	<code>vserver cifs session file show -vserver vserver_name -file-id integer</code>
On a specified SMB connection ID	<code>vserver cifs session file show -vserver vserver_name -connection-id integer</code>
On a specified SMB session ID	<code>vserver cifs session file show -vserver vserver_name -session-id integer</code>
On the specified hosting aggregate	<code>vserver cifs session file show -vserver vserver_name -hosting -aggregate aggregate_name</code>
On the specified volume	<code>vserver cifs session file show -vserver vserver_name -hosting -volume volume_name</code>
On the specified SMB share	<code>vserver cifs session file show -vserver vserver_name -share share_name</code>

If you want to display open SMB files...	Enter the following command...
On the specified SMB path	<pre>vserver cifs session file show -vserver vserver_name -path path</pre>
With the specified level of continuously available protection	<pre>vserver cifs session file show -vserver vserver_name -continuously -available continuously_available_status</pre> <p>The value for -continuously-available can be one of the following:</p> <ul style="list-style-type: none"> • No • Yes <p> If the continuously available status is No, this means that these open files are not capable of nondisruptively recovering from takeover and giveback. They also cannot recover from general aggregate relocation between partners in a high-availability relationship.</p>

If you want to display open SMB files...	Enter the following command...
With the specified reconnected state	<pre>vserver cifs session file show -vserver vserver_name -reconnected_reconnected_state</pre> <p>The value for <code>-reconnected</code> can be one of the following:</p> <ul style="list-style-type: none"> • No • Yes <p> If the reconnected state is No, the open file is not reconnected after a disconnection event. This can mean that the file was never disconnected, or that the file was disconnected and is not successfully reconnected. If the reconnected state is Yes, this means that the open file is successfully reconnected after a disconnection event.</p>

There are additional optional parameters that you can use to refine the output results. See the man page for more information.

Examples

The following example displays information about open files on SVM vs1:

```
cluster1::> vserver cifs session file show -vserver vs1
Node:      node1
Vserver:   vs1
Connection: 3151274158
Session:   1
File      File      Open Hosting          Continuously
ID        Type      Mode Volume     Share      Available
-----  -----
41       Regular    r    data      data      Yes
Path: \mytest.rtf
```

The following example displays detailed information about open SMB files with file ID 82 on SVM vs1:

```

cluster1::> vserver cifs session file show -vserver vs1 -file-id 82
-instance

          Node: node1
          Vserver: vs1
          File ID: 82
          Connection ID: 104617
          Session ID: 1
          File Type: Regular
          Open Mode: rw
Aggregate Hosting File: aggr1
Volume Hosting File: data1
          CIFS Share: data1
Path from CIFS Share: windows\win8\test\test.txt
          Share Mode: rw
          Range Locks: 1
Continuously Available: Yes
          Reconnected: No

```

The topics in this section show you how to configure and manage SAN environments with System Manager in ONTAP 9.7 and later releases.

If you are using the classic System Manager (available only in ONTAP 9.7 and earlier), see these topics:

- [iSCSI protocol](#)
- [FC/FCoE protocol](#)

You can use the iSCSI and FC protocols to provide storage in a SAN environment.

With iSCSI and FC, storage targets are called LUNs (logical units) and are presented to hosts as standard block devices. You create LUNs and then map them to initiator groups (igroups). Initiator groups are tables of FC host WWPs and iSCSI host node names and control which initiators have access to which LUNs.

FC targets connect to the network through FC switches and host-side adapters and are identified by world-wide port names (WWPNs). iSCSI targets connect to the network through standard Ethernet network adapters (NICs), TCP offload engine (TOE) cards with software initiators, converged network adapters (CNAs) or dedicated host bus adapters (HBAs) and are identified by iSCSI qualified names (IQNs).

Create LUNs to provide storage for an ESXi host using the FC or iSCSI SAN protocol. LUNs appear as disks to the ESXi host.

This procedure creates new LUNs on an existing storage VM. Your FC or iSCSI protocol should already be set up.

Beginning with ONTAP 9.8, when you provision storage, QoS is enabled by default. You can disable QoS or choose a custom QoS policy during the provisioning process or at a later time.

Steps

1. In System Manager, click **Storage > LUNs** and then click **Add**.
 - a. Enter the required information to create the LUN.
 - b. You can click **More Options** to do the following, depending upon your version of ONTAP.

Option	Available beginning with
Assign QoS policy to LUNs instead of parent volume <ul style="list-style-type: none">• More Options > Storage and Optimization• Select Performance Service Level.• To apply the QoS policy to individual LUNs instead of the entire volume, select Apply these performance limits enforcements to each LUN. <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;">By default, performance limits are applied at the volume level.</div>	ONTAP 9.10.1
Create a new initiator group using existing initiator groups <ul style="list-style-type: none">• More Options > HOST INFORMATION• Select New initiator group using existing initiator groups. <p>NOTE: The OS type for an igroup containing other igroups cannot be changed after it has been created.</p>	ONTAP 9.9.1
Add a description to your igroup or host initiator <p>The description serves as an alias for the igroup or host initiator.</p> <ul style="list-style-type: none">• More Options > HOST INFORMATION	ONTAP 9.9.1

Create your LUN on an existing volume	ONTAP 9.9.1
<p>By default, a new LUN is created in a new volume.</p> <ul style="list-style-type: none"> • More Options > Add LUNs • Select Group related LUNs. <p>Disable QoS or choose a custom QoS policy</p> <ul style="list-style-type: none"> • More Options > Storage and Optimization • Select Performance Service Level. <p>NOTE: In ONTAP 9.9.1 and later, if you select a custom QoS policy, you can also select manual placement on a specified local tier.</p>	ONTAP 9.8

2. For FC, zone your FC switches by WWPN. Use one zone per initiator and include all target ports in each zone.
3. Use Virtual Storage Console (VSC) for VMware vSphere, to discover and initialize the LUN.
4. Verify that the ESXi hosts can write and read data on the LUN.

== Other ways to do this in ONTAP

To perform these tasks with...	Refer to...
System Manager Classic (available with ONTAP 9.7 and earlier)	FC configuration for Windows overview iSCSI configuration for ESXi using VSC overview

:relative_path: ../
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/
```

Create LUNs to provide storage for a Linux server using the FC or iSCSI SAN protocol with ONTAP System Manager, which is available with ONTAP 9.7 and later ONTAP 9 releases.

This procedure creates new LUNs on an existing storage VM. LUNs appear to Linux as SCSI disk devices.

Your FC or iSCSI protocol should already be set up. You need to know the initiator identifiers (FC WWPN or iSCSI iqn) for your Linux server.

Beginning with ONTAP 9.8, when you provision storage, QoS is enabled by default. You can disable QoS or choose a custom QoS policy during the provisioning process or at a later time.

Steps

1. On your Linux server, install the [NetApp Linux Host Utilities](#) package.
2. In System Manager, click **Storage > LUNs** and then click **Add**.
 - a. Enter the required information to create the LUN.
 - b. You can click **More Options** to do the following, depending upon your version of ONTAP.

Option	Available beginning with
Assign QoS policy to LUNs instead of parent volume <ul style="list-style-type: none"> • More Options > Storage and Optimization • Select Performance Service Level. • To apply the QoS policy to individual LUNs instead of the entire volume, select Apply these performance limits enforcements to each LUN. <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> By default, performance limits are applied at the volume level. </div>	ONTAP 9.10.1
Create a new initiator group using existing initiator groups <ul style="list-style-type: none"> • More Options > HOST INFORMATION • Select New initiator group using existing initiator groups. <p>NOTE: The OS type for an igroup containing other igroups cannot be changed after it has been created.</p>	ONTAP 9.9.1
Add a description to your igroup or host initiator <p>The description serves as an alias for the igroup or host initiator.</p> <ul style="list-style-type: none"> • More Options > HOST INFORMATION 	ONTAP 9.9.1

Create your LUN on an existing volume	ONTAP 9.9.1
<p>By default, a new LUN is created in a new volume.</p> <ul style="list-style-type: none"> • More Options > Add LUNs • Select Group related LUNs. <p>Disable QoS or choose a custom QoS policy</p> <ul style="list-style-type: none"> • More Options > Storage and Optimization • Select Performance Service Level. <p>NOTE: In ONTAP 9.9.1 and later, if you select a custom QoS policy, you can also select manual placement on a specified local tier.</p>	ONTAP 9.8

3. For FC, zone your FC switches by WWPN. Use one zone per initiator and include all target ports in each zone.

4. On your Linux server, discover the new LUNs:

```
/usr/bin/rescan-scsi-bus.sh
```

Optionally partition the LUNs and create file systems.

5. Verify the Linux server can write and read data on the LUN.

Create LUNs to provide storage for a Windows server using the FC or iSCSI SAN protocol. LUNs appear as disks to the Windows host.

This procedure creates new LUNs on an existing storage VM. Your FC or iSCSI protocol should already

be set up.

Beginning with ONTAP 9.8, when you provision storage, QoS is enabled by default. You can disable QoS or choose a custom QoS policy during the provisioning process or at a later time.

Steps

1. On your Windows server, install the native DSM for Windows MPIO.
2. In System Manager, click **Storage > LUNs** and then click **Add**.
 - a. Enter the required information to create the LUN.
 - b. You can click **More Options** to do the following, depending upon your version of ONTAP.

Option	Available beginning with
Assign QoS policy to LUNs instead of parent volume <ul style="list-style-type: none">• More Options > Storage and Optimization• Select Performance Service Level.• To apply the QoS policy to individual LUNs instead of the entire volume, select Apply these performance limits enforcements to each LUN. <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;">By default, performance limits are applied at the volume level.</div>	ONTAP 9.10.1
Create a new initiator group using existing initiator groups <ul style="list-style-type: none">• More Options > HOST INFORMATION• Select New initiator group using existing initiator groups. <p>NOTE: The OS type for an igroup containing other igroups cannot be changed after it has been created.</p>	ONTAP 9.9.1
Add a description to your igroup or host initiator <p>The description serves as an alias for the igroup or host initiator.</p> <ul style="list-style-type: none">• More Options > HOST INFORMATION	ONTAP 9.9.1

Create your LUN on an existing volume By default, a new LUN is created in a new volume. • More Options > Add LUNs • Select Group related LUNs .	ONTAP 9.9.1
Disable QoS or choose a custom QoS policy • More Options > Storage and Optimization • Select Performance Service Level . NOTE: In ONTAP 9.9.1 and later, if you select a custom QoS policy, you can also select manual placement on a specified local tier.	ONTAP 9.8

3. For FC, zone your FC switches by WWPN. Use one zone per initiator and include all target ports in each zone.
4. On your Windows server, discover the new LUN.
5. Initialize the LUN and optionally format it with a file system.
6. Verify the Windows server can write and read data on the LUN.

Related information

If you want additional details about SAN administration, consult the [SAN Administration overview](#).

== Other ways to do this in ONTAP

To complete this task using...	Refer to...
System Manager Classic (available with 9.7 and earlier)	iSCSI configuration for Windows overview
The ONTAP command line interface (CLI)	LUN setup workflow with the CLI

```
= Create nested igrup
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrs:
:relative_path: ../
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/
```

Beginning with ONTAP 9.9.1, you can create an igrup that consists of other existing igrups.

1. In System Manager, click **Host > SAN Initiator Groups**, and then click **Add**.
2. Enter the igrup **Name** and **Description**.

The description serves as the igrup alias.

3. Select the **Storage VM** and **Host Operating System**.

The OS type of a nested igroup cannot be changed after the igroup is created.

4. Under **Initiator Group Members** select **Existing initiator group**.

You can use **Search** to find and select the initiator groups you want to add.

= Map igroups to multiple LUNs

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/

Beginning with ONTAP 9.9.1, you can map igroups to two or more LUNs simultaneously.

1. In System Manager, click **Storage > LUNs**.

2. Select the LUNs you want to map.

3. Click **More**, then click **Map To Initiator Groups**.

The selected igroups are added to the selected LUNs. The pre-existing mappings are not overwritten.

= Create and manage portsets

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/

In addition to [Selective LUN Map \(SLM\)](#), you can use portsets to further limit which LIFs can be used by an initiator to access a LUN.

Beginning with ONTAP 9.10.1, you can use System Manager to create portsets and bind them to igroups. You can also use System Manager to change the network interfaces associated with portsets and to delete portsets.

== Create a portset and bind to an igroup

If you do not bind a port set to an igroup, then all of the initiators in the igroup can access mapped LUNs through all of the LIFs on the node owning the LUN and the owning node's HA partner.

If you need to create a portset and bind it to an igroup in an ONTAP release earlier than 9.10.1 you must use the [ONTAP CLI procedure](#).

1. In System Manager, click **Network > Overview > Portsets**, and click **Add**.

2. Enter the information for the new portset and click **Add**.

3. Click **Hosts > SAN Initiator Groups**.

4. To bind the portset to a new igroup, click **Add**.

To bind the portset to an existing igroup, select the igroup, click , and then click **Edit Initiator Group**.

== Change network interfaces associated with a portset

1. In System Manager, click **Network > Overview > Portsets**.
2. Select the portset you want to edit and click , then select **Edit Portset**.

== Delete a portset

1. In System Manager, click **Network > Overview > Portsets**.
2. To delete a single portset, select the portset, click  and then select **Delete Portsets**.

To delete multiple portsets, select the portsets, and click **Delete**.

= Edit LUN QoS policy group

:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Beginning with ONTAP 9.10.1, you can use System Manager to assign or remove Quality of Service (QoS) policies on multiple LUNs at the same time.

If the QoS policy is assigned at the volume level, it must be changed at the volume level. You can only edit the QoS policy at the LUN level if it was originally assigned at the LUN level.

Steps

1. In System Manager, click **Storage > LUNs**.
2. Select the LUN or LUNs you want to edit.

If you are editing more than one LUN at a time, the LUNs must belong to the same Storage Virtual Machine (SVM). If you select LUNs that do not belong to the same SVM, the option to edit the QoS Policy Group is not displayed.

3. Click **More** and select **Edit QoS Policy Group**.

= Take a LUN offline

:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Beginning with ONTAP 9.10.1 you can use System Manager to take LUNs offline. Prior to ONTAP 9.10.1, you must use the ONTAP CLI to take LUNs offline.

== System Manager Procedure

Steps

1. In System Manager, click **Storage>LUNs**.
2. Take a single LUN or multiple LUNs offline

If you want to...

Do this...

Take a single LUN offline

Next to the LUN name, click  and select **Take Offline**.

Take multiple LUNs offline

- a. Select the LUNs you want to take offline.
- b. Click **More** and select **Take Offline**.

== CLI Procedure

You can only take one LUN offline at a time when using the CLI.

Step

1. Take the LUN offline: `lun offline lun_name -vserver SVM_name`

= NVMe storage

= Provision NVMe storage

```
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ../
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/
```

You can use the non-volatile memory express (NVMe) protocol to provide storage in a SAN environment. The NVMe protocol is optimized for performance with solid state storage.

For NVMe, storage targets are called namespaces. An NVMe namespace is a quantity of non-volatile storage that can be formatted into logical blocks and presented to a host as a standard block device. You create namespaces and subsystems, and then map the namespaces to the subsystems, similar to the way LUNs are provisioned and mapped to igroups for FC and iSCSI.

NVMe targets are connected to the network through a standard FC infrastructure using FC switches or a standard TCP infrastructure using Ethernet switches and host-side adapters.

The following NVMe protocols are supported:

Protocol	Beginning with ...	Allowed by...
TCP	ONTAP 9.10.1	Default
FCP	ONTAP 9.4	Default

Related information

- Provision NVMe storage for SUSE Linux with System Manager
- Configure an SVM for NVMe with the CLI

= Provision NVMe storage for SUSE Linux

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkattrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/

Create namespaces to provide storage for a SUSE Linux server using the NVMe protocol. Namespaces appear to Linux as SCSI disk devices.

This procedure creates new namespaces on an existing storage VM. Your storage VM must be configured for NVME, and your FC or TCP transport should already be set up.

Beginning with ONTAP 9.8, when you provision storage, QoS is enabled by default. You can disable QoS or choose a custom QoS policy during the provisioning process or at a later time.

Steps

1. In System Manager, click **Storage > NVMe Namespaces** and then click **Add**.

If you need to create a new subsystem, click **More Options**.

- a. If you are running ONTAP 9.8 or later and you want to disable QoS or choose a custom QoS policy, click **More Options** and then, under **Storage and Optimization** select **Performance Service Level**.
1. Zone your FC switches by WWPN. Use one zone per initiator and include all target ports in each zone.
 2. On your Linux server, discover the new namespaces.
 3. Initialize the namespace and format it with a file system.
 4. Verify the Linux server can write and read data on the namespace.

= Resizing a namespace

:icons: font

:relative_path: ./nvme/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/

Beginning with ONTAP 9.10.1, you can use the ONTAP CLI to increase or decrease the size of a NVMe namespace. You can use System Manager to increase the size of a NVMe namespace.

== Increase the size of a namespace

Using System Manager	Using the CLI
<ol style="list-style-type: none">1. Click Storage > NVMe Namespaces.2. Hoover over the namespace you want to increase, click , and then click Edit.3. Under CAPACITY, change the size of the namespace.	<ol style="list-style-type: none">1. Enter the following command: <code>vserver nvme namespace modify -vserver SMV_name -path path -size new_size_of_namespace</code>

== Decrease the size of a namespace

You must use the ONTAP CLI to decrease the size of a NVMe namespace.

1. Change the privilege setting to advanced:

```
set - privilege advanced
```

2. Decrease the size of the namespace:

```
vserver nvme namespace modify -vserver SMV_name -path namespace_path -size new_size_of_namespace
```

= SAN management with the CLI

= SAN administration overview with the CLI

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Use the following procedures to perform basic SAN host provisioning. You can configure and manage LUNs, igroups, and targets using the iSCSI and FC protocols, and namespaces and subsystems using the NVMe/FC protocol.

You should use these procedures under the following circumstances:

- You want to understand the range of ONTAP SAN host provisioning capabilities.
- You want to perform less common configuration and maintenance tasks, not basic SAN configuration.
- You want to use the command-line interface (CLI), not System Manager or an automated scripting tool.

= Set up LUNs for FC and iSCSI

= LUN guidelines

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The FC protocol and iSCSI protocol both provision storage through the use of LUNs. After you have setup your LUNs, you can perform various management tasks, such

as increasing or decreasing the size of a LUN. After configuring your volume and setting the appropriate OS type, you must complete the steps that are necessary to setup your LUN.

== Guidelines for assigning LUN IDs

Typically, the default LUN ID begins with 0 and is assigned in increments of 1 for each additional mapped LUN. The host associates the LUN ID with the location and path name of the LUN. The range of valid LUN ID numbers depends on the host. For detailed information, see the documentation provided with your Host Utilities.

== Guidelines for mapping LUNs to igroups

- You can map a LUN to only one igroup.
- You can map a LUN to only one specific initiator through the igroup.
- You can add a single initiator to multiple igroups, but the initiator can be mapped to only one LUN.
- You cannot use the same LUN ID for two LUNs mapped to the same igroup.
- You should use the same protocol type for igroups and port sets.

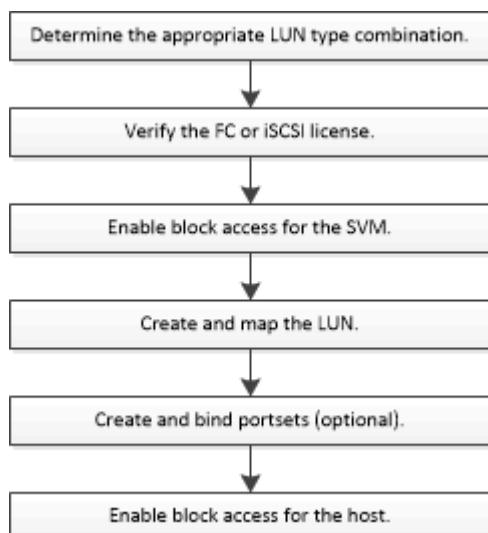

= LUN setup workflow

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

To set up your LUN, you must determine the best LUN type for your needs. Then you can follow a series of tasks to verify your protocol license, enable block access, create and map your LUN, and enable block access on your host. You can also optionally create and bind portsets as part of the LUN setup workflow.

== Other ways to do this in ONTAP

To complete this task using...	Refer to...
--------------------------------	-------------

The redesigned System Manager (available with 9.7 and later)	<ul style="list-style-type: none"> • Provision SAN storage for VMware datastores • Provision SAN storage for Linux servers • Provision SAN storage for Windows servers
System Manager Classic (available with 9.7 and earlier)	<ul style="list-style-type: none"> • FC configuration for ESXi using VSC • FC configuration for Red Hat Enterprise Linux • FC configuration for Windows • iSCSI configuration for ESXi using VSC • iSCSI configuration for Red Hat Enterprise Linux • iSCSI configuration for Windows

= Configure switches for FCoE

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You must configure your switches for FCoE before your FC service can run over the existing Ethernet infrastructure.

What you'll need

- Your SAN configuration must be supported.

For more information about supported configurations, see the Interoperability Matrix.

- A Unified Target Adapter (UTA) must be installed on your storage system.

If you are using a UTA2, it must be set to cna mode.

- A converged network adapter (CNA) must be installed on your host.

Steps

1. Use your switch documentation to configure your switches for FCoE.
2. Use the `dcb show` command to verify that the DCB settings for each node in the cluster have been correctly configured.

```
run -node node1 -command dcb show
```

DCB settings are configured on the switch. Consult your switch documentation if the settings are incorrect.

3. Use the `fcp adapter show` command to verify that the FCoE login is working when the FC target port online status is true.

```
cluster1::> fcp adapter show -fields
node,adapter,status,state,speed,fabric-established,physical-protocol
```

If the FC target port online status is false, consult your switch documentation.

Brocade products

= Prerequisites for setting up LUNs

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Setting up LUNs involves creating a LUN, creating an igroup, and mapping the LUN to the igroup. Your system must meet certain prerequisites before you can set up your LUNs.

- The Interoperability Matrix must list your SAN configuration as supported.
- Your SAN environment must meet the SAN host and controller configuration limits specified in [NetApp Hardware Universe](#) for your version of the ONTAP software.
- A supported version of Host Utilities must be installed.

The Host Utilities documentation provides more information.

- You must have SAN LIFs on the LUN owning node and the owning node's HA partner.

Related information

[NetApp Interoperability Matrix Tool](#)

[ONTAP SAN Host Configuration](#)

[NetApp Technical Report 4017: Fibre Channel SAN Best Practices](#)

= Verify the license for FC or iSCSI

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Before you can enable block access for a storage virtual machine (SVM) with FC or iSCSI, you must have a license.

Steps

1. Use the `system license show` command to verify that you have a license for FC or iSCSI.

```
system license show
```

Package	Type	Description	Expiration
<hr/>			
Base	site	Cluster Base License	-
NFS	site	NFS License	-
CIFS	site	CIFS License	-
iSCSI	site	iSCSI License	-
FCP	site	FCP License	-

2. If you do not have a license for FC or iSCSI, use the `license add` command.

```
license add -license-code your_license_code
```

= Configure an SVM for iSCSI

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

To configure a storage virtual machine (SVM) for iSCSI, you must create LIFs for the SVM and assign the iSCSI protocol to those LIFs.

About this task

You need a minimum of one iSCSI LIF per node for each SVM serving data with the iSCSI protocol. For redundancy, you should create at least two LIFs per node.

Steps

1. Enable the SVMs to listen for iSCSI traffic:

```
vserver iscsi create -vserver vserver_name -target-alias vserver_name
```

2. Create a LIF for the SVMs on each node to use for iSCSI:

```
network interface create -vserver vserver_name -lif lif_name -role data
-data-protocol iscsi -home-node node_name -home-port port_name -address
ip_address -netmask netmask
```

3. Verify that you set up your LIFs correctly:

```
network interface show -vserver vserver_name
```

4. Verify that iSCSI is up and running and the target IQN for that SVM:

```
vserver iscsi show -vserver vserver_name
```

5. From your host, create iSCSI sessions to your LIFs.

Related information

[NetApp Technical Report 4080: Best practices for modern SAN](#)

= Configure an SVM for FC
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

To configure a storage virtual machine (SVM) for FC, you must create LIFs for the SVM and assign the FC protocol to those LIFs.

What you'll need

You must have an FC license and it must be enabled. If the FC license is not enabled, the LIFs and SVMs appear to be online but the operational status is down. The FC service must be enabled for your LIFs and SVMs to be operational. You must use single initiator zoning for all of the FC LIFs in the SVM to host the initiators.

About this task

NetApp supports a minimum of one FC LIF per node for each SVM serving data with the FC protocol. You must use two LIFs per node and two fabrics, with one LIF per node attached. This provides for redundancy at the node layer and the fabric.

Steps

1. Enable FC service on the SVM:

```
vserver fcp create -vserver vserver_name -status-admin up
```

2. Create two LIFs for the SVMs on each node serving FC:

```
network interface create -vserver vserver_name -lif lif_name -role data  
-data-protocol fcp -home-node node_name -home-port port
```

The `-role` parameter should be `data` and the `data-protocol` parameter should be `fcp`.

3. Verify that your LIFs have been created and that their operational status is `online`:

```
network interface show -vserver vserver_name lif_name
```

[NetApp Support](#)

[NetApp Interoperability Matrix Tool](#)

[Considerations for LIFs in cluster SAN environments](#)

= Create LUNs and mapping to igroups
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

As part of configuring your SAN environment, you must create LUNs, create your initiator groups (igroups), and map your LUNs to your igroups.

What you'll need

- You must have created your aggregates, volumes, and storage virtual machines (SVMs).

- You must have enabled block access with FC or iSCSI.
- You must have created SAN LIFs on all of the nodes in the cluster.

About this task

When you create a LUN, you must specify the LUN OS type. The actual size of the LUN might vary slightly based on the OS type of the LUN. The LUN OS type cannot be modified after the LUN is created.

The metadata for each LUN requires approximately 64 KB of space in the containing aggregate. When you create a LUN, you must ensure that the containing aggregate has enough space for the LUN's metadata. If the aggregate does not contain enough space for the LUN's metadata, some hosts might not be able to access the LUN.

In ONTAP 9.4 and earlier, if necessary, you can grow your LUN up to 10 times its original size. For example, if you create a 100 GB LUN, you can grow that LUN to 1,000 GB. You cannot exceed 16 TB, which is the maximum LUN size. This limitation does not apply to ONTAP 9.5 and later.

The actual maximum size of the LUN might not be exactly 16 TB. ONTAP rounds down the limit to be slightly less.

Asymmetric logical unit access (ALUA) is always enabled during LUN creation. You cannot change the ALUA setting.

Steps

1. Create your LUNs:

```
lun create -vserver vserver_name -volume volume_name -lun lun_name -size
lun_size -ostype lun_ostype -space-reserve enabled|disabled
```

Your LUN name cannot exceed 255 characters and cannot contain spaces.

If your host operating system is Windows 2008 or later, use the windows_2008 ostype. The space-reserve option is enabled by default. If you want a non-space-reserved LUN, you must set the space-reserve option to disabled.

The NVFAIL option is automatically enabled when a LUN is created in a volume.

2. Create your igroups:

```
igroup create -vserver vserver_name -igroup igroup_name -protocol
fcp|iscsi|mixed -ostype lun_ostype -initiator initiator_name
```

If your host operating system is Windows 2008 or later, use the windows_2008 ostype.

3. Map your LUNs to igroups:

```
lun mapping create -vserver vserver_name -volume volume_name -lun lun_name
-igroup igroup_name
```

4. Verify that your LUNs are configured correctly:

```
lun show -vserver vserver_name
```

= Enable block access for a specific host

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You must enable block access on your specific host so that your initiators can access your targets.

What you'll need

- You must have network connectivity between the host and the LIFs on the SVM.
- Your FC or iSCSI service must be on and operational.
- You must have LUNs that are mapped to initiator groups (igroups).

Steps

1. Follow steps in your host documentation for enabling block access on your specific hosts.
2. Use the Host Utilities to complete the FC or iSCSI mapping and to discover your LUNs on the host.

Related information

[ONTAP SAN host configuration](#)

= Set up namespaces for NVMe

= NVMe namespaces considerations

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

To set up the NVMe protocol in your SAN environment, you must configure an SVM for NVMe, create namespaces and subsystems, configure an NVMe/FC LIF, and then map the namespaces to the subsystems. There are certain considerations you should be aware of when working with NVMe namespaces.

- If you lose data in a LUN, it cannot be restored from a namespace, or vice versa.
- The space guarantee for namespaces is the same as the space guarantee of the containing volume.
- Beginning with ONTAP 9.6, namespaces support 512 byte blocks and 4096 byte blocks.

4096 is the default value. 512 should only be used if the host operating system does not support 4096 byte blocks.

- Namespaces do not support the following:

- Renaming

You cannot rename a namespace.

- Resizing

You cannot increase or decrease the size of a namespace.

- Inter-volume move
- Inter-volume copy

= Configure an SVM for NVMe

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you want to use the NVMe protocol on a node, you must configure your SVM specifically for NVMe.

What you'll need

Your FC or Ethernet adapters must support NVMe. Supported adapters are listed in the [NetApp Hardware Universe](#).

Steps

1. If you do not want to use an existing SVM, create one:

```
vserver create -vserver SVM_name
```

- a. Verify that the SVM is created:

```
vserver show
```

2. Verify that you have NVMe or TCP capable adapters installed in your cluster:

For NVMe: network fcp adapter show -data-protocols-supported fc-nvme

For TCP: network port show

3. If you are running ONTAP 9.7 or earlier, remove all protocols from the SVM:

```
vserver remove-protocols -vserver SVM_name -protocols
iscsi,fcp,nfs,cifs,ndmp
```

Beginning with ONTAP 9.8, it is not necessary to remove other protocols when adding NVMe.

4. Add the NVMe protocol to the SVM:

```
vserver add-protocols -vserver SVM_name -protocols nvme
```

5. If you are running ONTAP 9.7 or earlier, verify that NVMe is the only protocol allowed on the SVM:

```
vserver show -vserver SVM_name -fields allowed-protocols
```

NVMe should be the only protocol displayed under the allowed protocols column.

6. Create the NVMe service:

```
vserver nvme create -vserver SVM_name
```

7. Verify that the NVMe service was created:

```
vserver nvme show -vserver SVM_name
```

The Administrative Status of the SVM should be listed as up.

8. Create an NVMe/FC LIF:

ONTAP version	Applicable protocols	Command
ONTAP 9.9.1 or earlier	FC	<pre>network interface create -vserver SVM_name -lif lif_name -role data -data-protocol fc-nvme -home-node home_node -home-port home_port</pre>
ONTAP 9.10.1	FC or TCP	<pre>network interface create -vserver SVM_name -lif lif_name -service-policy {default-data-nvme-tcp default-data-nvme-fc} -home-node home_node -home-port home_port -status admin up -failover-policy disabled -firewall -policy data -auto -revert false -failover -group failover_group -is-dns-update-enabled false</pre>

9. Create an NVMe/FC LIF on the HA partner node:

ONTAP version	Applicable protocols	Command
ONTAP 9.9.1 or earlier	FC	<pre>network interface create -vserver SVM_name -lif lif_name -role data -data-protocol fc-nvme -home-node home_node -home-port home_port</pre>

ONTAP version	Applicable protocols	Command
ONTAP 9.10.1 or later	FC or TCP	<pre>network interface create -vserver SVM_name -lif lif_name -service-policy {default-data-nvme-tcp default-data-nvme-fc} -home-node home_node -home-port home_port -status admin up -failover-policy disabled -firewall -policy data -auto -revert false -failover -group failover_group -is-dns-update-enabled false</pre>

10. Verify the NVMe/FC LIFs were created:

```
network interface show -vserver SVM_name
```

11. Create volume on the same node as the LIF:

```
vol create -vserver SVM_name -volume vol_name -aggregate aggregate_name
-size volume_size
```

If a warning message is displayed about the auto efficiency policy, it can be safely ignored.

= Create an NVMe namespace and subsystem
 :icons: font
 :relative_path: ./san-admin/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

For systems using the NVMe protocol, you must create one or more NVMe namespaces and subsystems. Each namespace can then be mapped to an NVMe subsystem to allow data access from your host system.

What you'll need

The SVM must already be configured for NVMe.

Steps

1. Verify that the SVM is configured for NVMe:

```
vserver show -vserver SVM_name -fields allowed-protocols
```

NVMe should be displayed under the allowed-protocols column.

2. Create the NVMe namespace:

```
vserver nvme namespace create -vserver SVM_name -path path -size
```

```
size_of_namespace -ostype OS_type
```

3. Create the NVMe subsystem:

```
vserver nvme subsystem create -vserver SVM_name -subsystem  
name_of_subsystem -ostype OS_type
```

4. Verify that the subsystem was created:

```
vserver nvme subsystem show -vserver SVM_name
```

The nvme subsystem should be displayed under the Subsystem column.

= Map an NVMe namespace to a subsystem

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You must map a namespace to a subsystem when using NVMe.

What you'll need

- You must have configured an SVM for NVMe.
- You must have created an NVMe namespace and subsystem.

About this task

A namespace can only be mapped to a single subsystem.

Steps

1. Obtain the NQN from the host.

2. Add the host NQN to the subsystem:

```
vserver nvme subsystem host add -vserver SVM_name -subsystem subsystem_name  
-host-nqn Host_NQN:subsystem.subsystem_name
```

3. Map the namespace to the subsystem:

```
vserver nvme subsystem map add -vserver SVM_name -subsystem subsystem_name  
-path path
```

4. Verify that the namespace is mapped to the subsystem:

```
vserver nvme namespace show -vserver SVM_name -instance
```

The subsystem should be listed as the Attached subsystem.

= Manage LUNs for FC and iSCSI

= Increase the size of a LUN

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The size to which you can increase your LUN varies depending upon your version of ONTAP.

ONTAP version	Maximum LUN size
ONTAP 9.8 and later	<ul style="list-style-type: none">• 128 TB for All SAN Arrays (ASAs)• 16 TB for non-ASAs
ONTAP 9.5, 9.6, 9.7	16TB
ONTAP 9.4 or earlier	10 times the original LUN size, but not greater than 16TB For example, if you create a 100 GB LUN, you can only grow it to 1,000 GB.

You do not need to take the LUN offline to increase the size. However, after you have increased the size, you must rescan the LUN on the host for the host to recognize the change in size.

See the Command Reference page for the `lun resize` command for more information about resizing a LUN.

Solaris LUNs cannot be resized.

Steps

1. Increase the size of the LUN:

```
lun resize -vserver vserver_name -volume volume_name -lun lun_name -size
lun_size
```

2. Verify the increased LUN size:

```
lun show -vserver vserver_name
```

ONTAP operations round down the actual maximum size of the LUN so it is slightly less than the expected value. Also, actual LUN size might vary slightly based on the OS type of the LUN. To obtain the exact resized value, run the following commands in advanced mode:

```
set -unit B
```

```
lun show -fields max-resize-size -volume volume_name -lun
lun_name
```

3. Rescan the LUN on the host.

4. Follow your host documentation to make the newly created LUN size visible to the host file system.

= Decrease the size of a LUN

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

Before you decrease the size of a LUN, the host needs to migrate the blocks containing the LUN data into the boundary of the smaller LUN size. You should use a tool such as SnapDrive for Windows to ensure that the LUN is properly decreased without truncating blocks containing LUN data. Manually decreasing the size of your LUN is not recommended.

About this task

After you decrease the size of your LUN, ONTAP automatically notifies the initiator that the LUN size has decreased. However, additional steps might be required on your host for the host to recognize the new LUN size. Check your host documentation for specific information about decreasing the size of the host file structure.

= Move a LUN

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can move a LUN across volumes within a storage virtual machine (SVM), but you cannot move a LUN across SVMs. LUNs moved across volumes within an SVM are moved immediately and without loss of connectivity.

What you'll need

If your LUN is using Selective LUN Map (SLM), the SLM reporting nodes must have been modified to include the destination node and its HA partner.

About this task

Storage efficiency features, such as deduplication, compression, and compaction are not preserved during a LUN move. They must be reapplied after the LUN move is completed.

Data protection through Snapshot copies occurs at the volume level. Therefore, when you move a LUN, it falls under the data protection scheme of the destination volume. If you do not have Snapshot copies established for the destination volume, Snapshot copies of the LUN are not created. Also, all of the Snapshot copies of the LUN stay in the original volume until those Snapshot copies are deleted.

You cannot move a LUN to the following volumes:

- A SnapMirror destination volume
- The SVM root volume

You cannot move the following types of LUNs:

- A LUN that has been created from a file
- A LUN that is in NVFail state
- A LUN that is in a load-sharing relationship
- A protocol-endpoint class LUN

For Solaris os_type LUNs that are 1 TB or larger, the host might experience a timeout during the LUN move. For this LUN type, you should unmount the LUN before initiating the move.

== System Manager procedure

Beginning with ONTAP 9.10.1, you can use System Manager to create a new volume when you move a single LUN. In ONTAP 9.8 and 9.9.1, the volume to which you are moving your LUN must exist before you begin the LUN move.

Steps

1. In System Manager, click **Storage>LUNs**.
2. Right click the LUN you want to move, then click  and select **Move LUN**.

In ONTAP 9.10.1, select to move the LUN to **An existing volume** or to a **New volume**.

If you select to create a new volume, provide the volume specifications.

3. Click **Move**.

== CLI procedure

Steps

1. Move the LUN:

```
lun move start.
```

During a very brief period, the LUN is visible on both the origin and destination volume. This is expected and is resolved upon completion of the move.

2. Track the status of the move and verify successful completion:

```
lun move show.
```

- [Selective LUN Map](#)
- [Modifying the SLM reporting-nodes list](#)

= Delete LUNs

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can delete a LUN from a storage virtual machine (SVM) if you no longer need the LUN.

What you'll need

The LUN must be unmapped from its igroup before you can delete it.

Steps

1. Verify that the application or host is not using the LUN.
2. Unmap the LUN from the igroup:

```
lun mapping delete
```

```
lun mapping delete -vserver vs5 -volume vo5 -lun lun5 -igroup igr5
```

3. Delete the LUN:

```
lun delete
```

```
lun delete -vserver vs5 -volume vol5 -lun lun5
```

4. Verify that you deleted the LUN:

```
lun show
```

```
lun show -vserver vs5
```

Vserver	Path	State	Mapped	Type	Size
vs5	/vol/vol16/lun8	online	mapped	windows	10.00GB

= Considerations for copying LUNs

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

There are considerations you should be aware of when copying a LUN.

Cluster administrators can copy a LUN across storage virtual machines (SVMs) within the cluster by using the `lun copy` command. Cluster administrators must establish the storage virtual machine (SVM) peering relationship using the `vserver peer create` command before an inter-SVM LUN copy operation is performed. There must be enough space in the source volume for a SIS clone.

LUNs in Snapshot copies can be used as source LUNs for the `lun copy` command. When you copy a LUN using the `lun copy` command, the LUN copy is immediately available for read and write access. The source LUN is unchanged by creation of a LUN copy. Both the source LUN and the LUN copy exist as unique LUNs with different LUN serial numbers. Changes made to the source LUN are not reflected in the LUN copy, and changes made to the LUN copy are not reflected in the source LUN. The LUN mapping of the source LUN is not copied to the new LUN; the LUN copy must be mapped.

Data protection through Snapshot copies occurs at the volume level. Therefore, if you copy a LUN to a volume different from the volume of the source LUN, the destination LUN falls under the data protection scheme of the destination volume. If you do not have Snapshot copies established for the destination volume, Snapshot copies are not created of the LUN copy.

Copying LUNs is a nondisruptive operation.

You cannot copy the following types of LUNs:

- A LUN that has been created from a file
- A LUN that is in NVFAIL state
- A LUN that is in a load-sharing relationship
- A protocol-endpoint class LUN

= Ways to limit LUN access with port sets and igroups

:icons: font

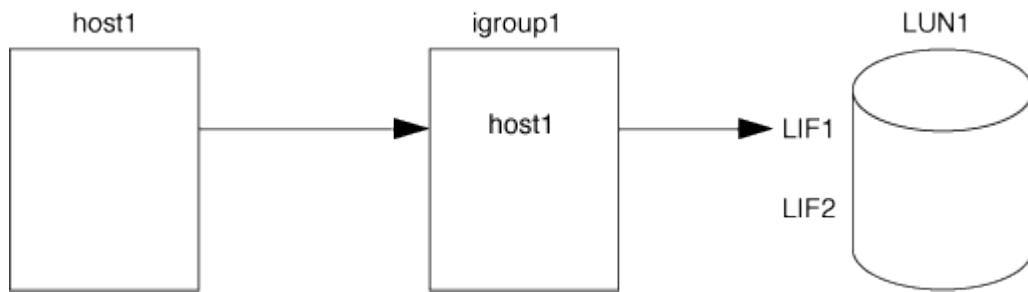

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

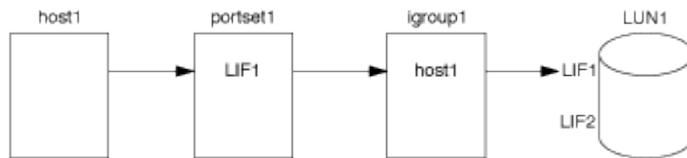

In addition to using Selective LUN Map (SLM), you can limit access to your LUNs through igroups and port sets.

Port sets can be used with SLM to further restrict access of certain targets to certain initiators. When using SLM with port sets, LUNs will be accessible on the set of LIFs in the port set on the node that owns the LUN and on that node's HA partner.

In the following example, initiator1 does not have a port set. Without a port set, initiator1 can access LUN1 through both LIF1 and LIF2.

You can limit access to LUN1 by using a port set. In the following example, initiator1 can access LUN1 only through LIF1. However, initiator1 cannot access LUN1 through LIF2 because LIF2 is not in port set1.

Related information

- [Selective LUN Map](#)
- [Create port sets and binding igroups to port sets](#)

= Examine configured and used space of a LUN

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Knowing the configured space and actual space used for your LUNs can help you determine the amount of space that can be reclaimed when doing space reclamation, the amount of reserved space that contains data, and the total configured size versus the actual size used for a LUN.

Step

1. View the configured space versus the actual space used for a LUN:

```
lun show
```

The following example show the configured space versus the actual space used by the LUNs in the vs3 storage virtual machine (SVM):

```
lun show -vserver vs3 -fields path, size, size-used, space-reserve
```

vserver	path	size	space-reserve	size-used
vs3	/vol/vol0/lun1	50.01GB	disabled	25.00GB
vs3	/vol/vol0/lun1_backup	50.01GB	disabled	32.15GB
vs3	/vol/vol0/lun2	75.00GB	disabled	0B
vs3	/vol/vospace/lun0	5.00GB	enabled	4.50GB
4 entries were displayed.				

= Control and monitor I/O performance to LUNs by using Storage QoS

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can control input/output (I/O) performance to LUNs by assigning LUNs to Storage QoS policy groups. You might control I/O performance to ensure that workloads achieve specific performance objectives or to throttle a workload that negatively impacts other workloads.

About this task

Policy groups enforce a maximum throughput limit (for example, 100 MB/s). You can create a policy group without specifying a maximum throughput, which enables you to monitor performance before you control the workload.

You can also assign storage virtual machines (SVMs) with FlexVol volumes and LUNs to policy groups.

Note the following requirements about assigning a LUN to a policy group:

- The LUN must be contained by the SVM to which the policy group belongs.
You specify the SVM when you create the policy group.
- If you assign a LUN to a policy group, then you cannot assign the LUN's containing volume or SVM to a policy group.

For more information about how to use Storage QoS, see the [System administration reference](#).

Steps

1. Use the `qos policy-group create` command to create a policy group.
2. Use the `lun create` command or the `lun modify` command with the `-qos-policy-group` parameter to assign a LUN to a policy group.
3. Use the `qos statistics` commands to view performance data.
4. If necessary, use the `qos policy-group modify` command to adjust the policy group's maximum throughput limit.

= Tools available to effectively monitor your LUNs

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Tools are available to help you effectively monitor your LUNs and avoid running out of space.

- Active IQ Unified Manager is a free tool that enables you to manage all storage across all clusters in your environment.
- System Manager is a graphical user interface built into ONTAP that enables you to manually manage storage needs at the cluster level.
- OnCommand Insight presents a single view of your storage infrastructure and enables you to set up automatic monitoring, alerts, and reporting when your LUNs, volumes, and aggregates are running out of storage space.

= Considerations for transitioning SAN configurations

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

In a SAN environment, a disruption in service is required during the transition of a 7-Mode volume to ONTAP. You need to shut down your hosts to complete the transition. After transition, you must update your host configurations before you can begin serving data in ONTAP

You need to schedule a maintenance window during which you can shut down your hosts and complete the transition.

== Capabilities and restrictions of transitioned LUNs

LUNs that have been transitioned from Data ONTAP operating in 7-Mode to ONTAP have certain capabilities and restrictions that affect the way the LUNs can be managed.

You can do the following with transitioned LUNs:

- View the LUN using the `lun show` command
- View the inventory of LUNs transitioned from the 7-Mode volume using the `transition 7-mode show` command
- Restore a volume from a 7-Mode Snapshot copy

Restoring the volume transitions all of the LUNs captured in the Snapshot copy

- Restore a single LUN from a 7-Mode Snapshot copy using the `snapshot restore-file` command
- Create a clone of a LUN in a 7-Mode Snapshot copy
- Restore a range of blocks from a LUN captured in a 7-Mode Snapshot copy
- Create a FlexClone of the volume using a 7-Mode Snapshot copy

You cannot do the following with transitioned LUNs:

- Access Snapshot copy-backed LUN clones captured in the volume

Related information

[Copy-based transition](#)

= I/O misalignments on properly aligned LUNs overview

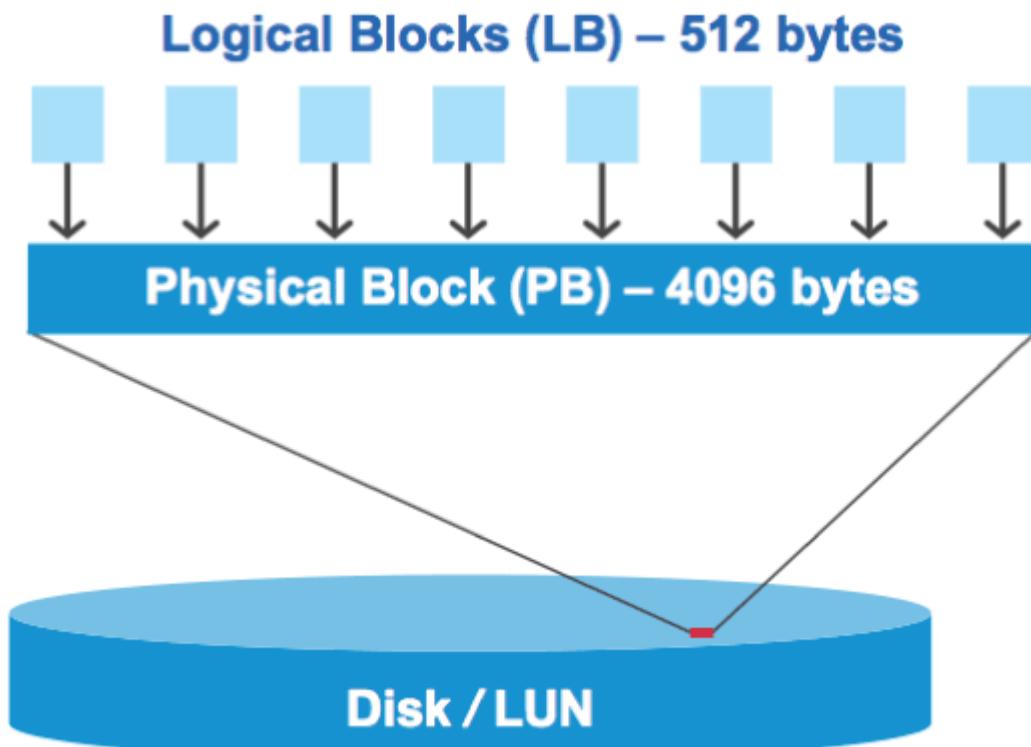

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ONTAP might report I/O misalignments on properly aligned LUNs. In general, these misalignment warnings can be disregarded as long as you are confident that your LUN is properly provisioned and your partitioning table is correct.

LUNs and hard disks both provide storage as blocks. Because the block size for disks on the host is 512 bytes, LUNs present blocks of that size to the host while actually using larger, 4-KB blocks to store data. The 512-byte data block used by the host is referred to as a logical block. The 4-KB data block used by the LUN to store data is referred to as a physical block. This means that there are eight 512-byte logical blocks in each 4-KB physical block.

The host operating system can begin a read or write I/O operation at any logical block. I/O operations are only considered aligned when they begin at the first logical block in the physical block. If an I/O operation begins at a logical block that is not also the start of a physical block, the I/O is considered misaligned. ONTAP automatically detects the misalignment and reports it on the LUN. However, the presence of misaligned I/O does not necessarily mean that the LUN is also misaligned. It is possible for misaligned I/O to be reported on properly aligned LUNs.

If further investigation is required, technical support can run diagnostic commands that show detailed I/O alignment data to confirm the presence or absence of true LUN misalignment.

For more information about tools for correcting alignment problems, see the following documentation: +

- [Windows Unified Host Utilities 7.1](#)
- [Virtual Storage Console for VMware vSphere Installation and Administration Guide](#)

== Achieve I/O alignment using LUN OS types

To achieve I/O alignment with your OS partitioning scheme, you should use the recommended ONTAP LUN `ostype` value that most closely matches your operating system.

The partition scheme employed by the host operating system is a major contributing factor to I/O misalignments. Some ONTAP LUN `ostype` values use a special offset known as a “prefix” to enable the default partitioning scheme used by the host operating system to be aligned.

In some circumstances, a custom partitioning table might be required to achieve I/O alignment. However, for `ostype` values with a “prefix” value greater than 0, a custom partition might create misaligned I/O.

The LUN `ostype` values in the following table should be used based on your operating system.

LUN <code>ostype</code>	Prefix (bytes)	Prefix (sectors)	Operating system
windows	32,256	63	Windows 2000, 2003 (MBR format)
windows_gpt	17,408	34	Windows 2003 (GPT format)
windows_2008	0	0	Windows 2008 and later
linux	0	0	All Linux distributions
xen	0	0	Citrix XenServer
vmware	0	0	VMware ESX
solaris	1MB	2,048	Solaris
solaris_efi	17,408	34	Solaris
hpux	0	0	HP-UX
aix	0	0	AIX

== Special I/O alignment considerations for Linux

Linux distributions offer a wide variety of ways to use a LUN including as raw devices for databases, various volume managers, and file systems. It is not necessary to create partitions on a LUN when used

as a raw device or as physical volume in a logical volume.

For RHEL 5 and earlier and SLES 10 and earlier, if the LUN will be used without a volume manager, you should partition the LUN to have one partition that begins at an aligned offset, which is a sector that is an even multiple of eight logical blocks.

== Special I/O alignment considerations for Solaris LUNs

You need to consider various factors when determining whether you should use the `solaris` `ostype` or the `solaris_efi` `ostype`.

See the [Solaris Host Utilities Installation and Administration Guide](#) for detailed information.

== ESX boot LUNs report as misaligned

LUNs used as ESX boot LUNs are typically reported by ONTAP as misaligned. ESX creates multiple partitions on the boot LUN, making it very difficult to align. Misaligned ESX boot LUNs are not typically a performance problem because the total amount of misaligned I/O is small. Assuming that the LUN was correctly provisioned with the VMware `ostype`, no action is needed.

Related information

[Guest VM file system partition/disk alignment for VMware vSphere, other virtual environments, and NetApp storage systems](#)

= Ways to address issues when LUNs go offline

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

When no space is available for writes, LUNs go offline to preserve data integrity. LUNs can run out of space and go offline for various reasons, and there are several ways you can address the issue.

If the...	You can...
Aggregate is full	<ul style="list-style-type: none">Add more disks.Use the <code>volume modify</code> command to shrink a volume that has available space.If you have space-guarantee volumes that have available space, change the volume space guarantee to <code>none</code> with the <code>volume modify</code> command.

If the...	You can...
Volume is full but there is space available in the containing aggregate	<ul style="list-style-type: none"> For space guarantee volumes, use the <code>volume modify</code> command to increase the size of your volume. For thinly provisioned volumes, use the <code>volume modify</code> command to increase the maximum size of your volume. <p>If volume autogrow is not enabled, use <code>volume modify -autogrow-mode</code> to enable it.</p> <ul style="list-style-type: none"> Delete Snapshot copies manually with the <code>volume snapshot delete</code> command, or use the <code>volume snapshot autodelete</code> command to automatically delete Snapshot copies.

[Logical storage management](#)

= Recommended volume and file or LUN configuration combinations

= Recommended volume and file or LUN configuration combinations overview

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

There are specific combinations of FlexVol volume and file or LUN configurations you can use, depending on your application and administration requirements.

Understanding the benefits and costs of these combinations can help you determine the right volume and LUN configuration combination for your environment.

The following volume and LUN configuration combinations are recommended:

- Space-reserved files or LUNs with thick volume provisioning
- Non-space-reserved files or LUNs with thin volume provisioning
- Space-reserved files or LUNs with semi-thick volume provisioning

You can use SCSI thin provisioning on your LUNs in conjunction with any of these configuration combinations.

-- Space-reserved files or LUNs with thick volume provisioning

Benefits:

- All write operations within space-reserved files are guaranteed; they will not fail due to insufficient space.

- There are no restrictions on storage efficiency and data protection technologies on the volume.

Costs and limitations:

- Enough space must be set aside from the aggregate up front to support the thickly provisioned volume.
- Space equal to twice the size of the LUN is allocated from the volume at LUN creation time.

== Non-space-reserved files or LUNs with thin volume provisioning

Benefits:

- There are no restrictions on storage efficiency and data protection technologies on the volume.
- Space is allocated only as it is used.

Costs and restrictions:

- Write operations are not guaranteed; they can fail if the volume runs out of free space.
- You must manage the free space in the aggregate effectively to prevent the aggregate from running out of free space.

== Space-reserved files or LUNs with semi-thick volume provisioning

Benefits:

Less space is reserved up front than for thick volume provisioning, and a best-effort write guarantee is still provided.

Costs and restrictions:

- Write operations can fail with this option.

You can mitigate this risk by properly balancing free space in the volume against data volatility.

- You cannot rely on retention of data protection objects such as Snapshot copies and FlexClone files and LUNs.
- You cannot use ONTAP block-sharing storage efficiency capabilities that cannot be automatically deleted, including deduplication, compression, and ODX/Copy Offload.

= Determine the correct volume and LUN configuration combination for your environment

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

Answering a few basic questions about your environment can help you determine the best FlexVol volume and LUN configuration for your environment.

About this task

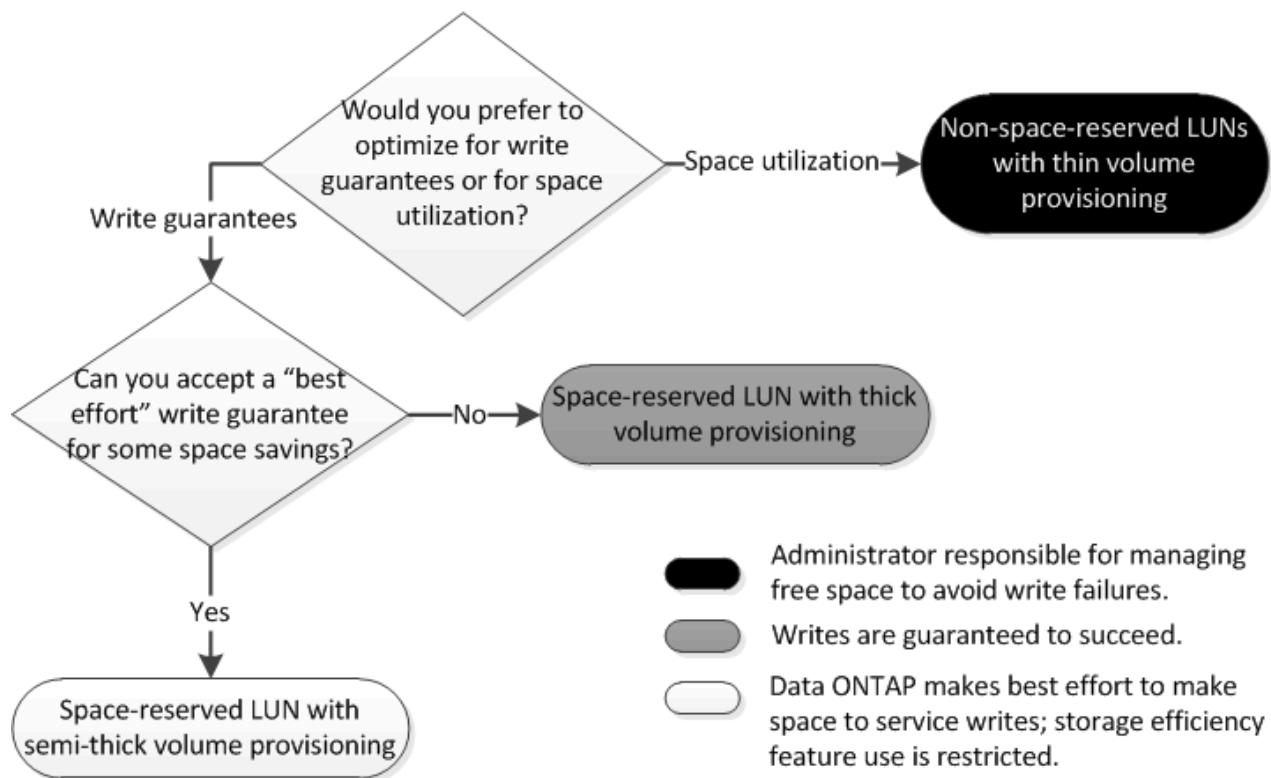

You can optimize your LUN and volume configurations for maximum storage utilization or for the security of write guarantees. Based on your requirements for storage utilization and your ability to monitor and replenish free space quickly, you must determine the FlexVol volume and LUN volumes appropriate for your installation.

You do not need a separate volume for each LUN.

Step

1. Use the following decision tree to determine the best volume and LUN configuration combination for your environment:

= Calculate rate of data growth for LUNs

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

You need to know the rate at which your LUN data is growing over time to determine whether you should use space-reserved LUNs or non-space-reserved LUNs.

About this task

If you have a consistently high rate of data growth, then space-reserved LUNs might be a better option for you. If you have a low rate of data growth, then you should consider non-space-reserved LUNs.

You can use tools such as OnCommand Insight to calculate your rate of data growth or you can calculate it manually. The following steps are for manual calculation.

Steps

1. Set up a space-reserved LUN.
2. Monitor the data on the LUN for a set period of time, such as one week.

Make sure that your monitoring period is long enough to form a representative sample of regularly occurring increases in data growth. For instance, you might consistently have a large amount of data growth at the end of each month.

3. Each day, record in GB how much your data grows.
4. At the end of your monitoring period, add the totals for each day together, and then divide by the number of days in your monitoring period.

This calculation yields your average rate of growth.

Example

In this example, you need a 200 GB LUN. You decide to monitor the LUN for a week and record the following daily data changes:

- Sunday: 20 GB
- Monday: 18 GB
- Tuesday: 17 GB
- Wednesday: 20 GB
- Thursday: 20 GB
- Friday: 23 GB
- Saturday: 22 GB

In this example, your rate of growth is $(20+18+17+20+20+23+22) / 7 = 20$ GB per day.

= Configuration settings for space-reserved files or LUNs with thick-provisioned volumes

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

This FlexVol volume and file or LUN configuration combination provides the ability to use storage efficiency technologies and does not require you to actively monitor your free space, because sufficient space is allocated up front.

The following settings are required to configure a space-reserved file or LUN in a volume using thick provisioning:

Volume setting	Value
Guarantee	Volume
Fractional reserve	100
Snapshot reserve	Any
Snapshot autodelete	Optional
Autogrow	Optional; if enabled, aggregate free space must be actively monitored.

File or LUN setting	Value
Space reservation	Enabled

= Configuration settings for non-space-reserved files or LUNs with thin-provisioned volumes

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

This FlexVol volume and file or LUN configuration combination requires the smallest amount of storage to be allocated up front, but requires active free space management to prevent errors due to lack of space.

The following settings are required to configure a non-space-reserved files or LUN in a thin-provisioned volume:

Volume setting	Value
Guarantee	None
Fractional reserve	0
Snapshot reserve	Any
Snapshot autodelete	Optional
Autogrow	Optional

File or LUN setting	Value
Space reservation	Disabled

== Additional considerations

When the volume or aggregate runs out of space, write operations to the file or LUN can fail.

If you do not want to actively monitor free space for both the volume and the aggregate, you should enable Autogrow for the volume and set the maximum size for the volume to the size of the aggregate. In this configuration, you must monitor aggregate free space actively, but you do not need to monitor the free space in the volume.

= Configuration settings for space-reserved files or LUNs with semi-thick volume provisioning

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

This FlexVol volume and file or LUN configuration combination requires less storage to be allocated up front than the fully provisioned combination, but places restrictions on the efficiency technologies you can use for the volume. Overwrites are fulfilled on

a best-effort basis for this configuration combination.

The following settings are required to configure a space-reserved LUN in a volume using semi-thick provisioning:

Volume setting	Value
Guarantee	Volume
Fractional reserve	0
Snapshot reserve	0
Snapshot autodelete	On, with a commitment level of destroy, a destroy list that includes all objects, the trigger set to volume, and all FlexClone LUNs and FlexClone files enabled for automatic deletion.
Autogrow	Optional; if enabled, aggregate free space must be actively monitored.

File or LUN setting	Value
Space reservation	Enabled

== Technology restrictions

You cannot use the following volume storage efficiency technologies for this configuration combination:

- Compression
- Deduplication
- ODX and FlexClone Copy Offload
- FlexClone LUNs and FlexClone files not marked for automatic deletion (active clones)
- FlexClone subfiles
- ODX/Copy Offload

== Additional considerations

The following facts must be considered when employing this configuration combination:

- When the volume that supports that LUN runs low on space, protection data (FlexClone LUNs and files, Snapshot copies) is destroyed.
- Write operations can time out and fail when the volume runs out of free space.

Compression is enabled by default for AFF platforms. You must explicitly disable compression for any volume for which you want to use semi-thick provisioning on an AFF platform.

= Selective LUN Map

= Selective LUN Map overview

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Selective LUN Map (SLM) reduces the number of paths from the host to the LUN. With SLM, when a new LUN map is created, the LUN is accessible only through paths on the node owning the LUN and its HA partner.

SLM enables management of a single igroup per host and also supports nondisruptive LUN move operations that do not require portset manipulation or LUN remapping.

Portsets can be used with SLM just as in previous versions of ONTAP to further restrict access of certain targets to certain initiators. When using SLM with portsets, LUNs will be accessible on the set of LIFs in the portset on the node that owns the LUN and on that node's HA partner.

SLM is enabled by default on all new LUN maps.

= Determine whether SLM is enabled on a LUN map

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If your environment has a combination of LUNs created in ONTAP and LUNs transitioned from previous versions, you might need to determine whether Selective LUN Map (SLM) is enabled on a specific LUN.

You can use the information displayed in the output of the `lun mapping show -fields reporting-nodes, node` command to determine whether SLM is enabled on your LUN map. If SLM is not enabled, "-" is displayed in the cells under the `reporting-nodes` column of the command output. If SLM is enabled, the list of nodes displayed under the `nodes` column is duplicated in the `reporting-nodes` column.

= Create port sets and binding igroups to port sets

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

In addition to using Selective LUN Map (SLM), you can create a port set and bind the port set to an igroup to further limit which LIFs can be used by an initiator to access a LUN. If you do not bind a port set to an igroup, then all of the initiators in the igroup can access mapped LUNs through all of the LIFs on the node owning the LUN and the owning node's HA partner.

What you'll need

You must have at least one LIF and one igroup.

Unless you are using interface groups, two LIFs are recommended for redundancy for both iSCSI and FC. Only one LIF is recommended for interface groups.

About this task

It is advantageous to use ports sets with SLM when you have more than two LIFs on a node and you

want to restrict a certain initiator to a subset of LIFs. Without port sets, all targets on the node will be accessible by all of the initiators with access to the LUN through the node owning the LUN and the owning node's HA partner.

Steps

1. Create a port set containing the appropriate LIFs:

```
portset create -vserver vserver_name -portset portset_name -protocol protocol -port-name port_name
```

If you are using FC, specify the `protocol` parameter as `fcp`. If you are using iSCSI, specify the `protocol` parameter as `iscsi`.

2. Bind the igroup to the port set:

```
lun igrup bind -vserver vserver_name -igroup igroup_name -portset portset_name
```

3. Verify that your port sets and LIFs are correct:

```
portset show -vserver vserver_name
```

Vserver	Portset	Protocol	Port Names	Igroups
vs3	portset0	iscsi	lif0,lif1	igroup1

= Modify the SLM reporting-nodes list

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

If you are moving a LUN or a volume containing LUNs to another high availability (HA) pair within the same cluster, you should modify the Selective LUN Map (SLM) reporting-nodes list before initiating the move to ensure that active, optimized LUN paths are maintained.

Steps

1. Add the destination node and its partner node to the reporting-nodes list of the aggregate or volume:

```
lun mapping add-reporting-nodes -vserver vserver_name -path lun_path -igroup igroup_name [-destination-aggregate aggregate_name|-destination-volume volume_name]
```

If you have a consistent naming convention, you can modify multiple LUN mappings at the same time by using `-igroup` instead of `igroup`.

2. Rescan the host to discover the newly added paths.
3. If your OS requires it, add the new paths to your multipath network I/O (MPIO) configuration.
4. Run the command for the needed move operation and wait for the operation to finish.

5. Verify that I/O is being serviced through the Active/Optimized path:

```
lun mapping show -fields reporting-nodes
```

6. Remove the previous LUN owner and its partner node from the reporting-nodes list:

```
lun mapping remove-reporting-nodes -vserver vserver_name -path lun_path  
-igroup igrup_name -remote-nodes
```

7. Verify that the LUN has been removed from the existing LUN map:

```
lun mapping show -fields reporting-nodes
```

8. Remove any stale device entries for the host OS.

9. Change any multipathing configuration files if required.

10. Rescan the host to verify removal of old paths.

See your host documentation for specific steps to rescan your hosts.

= Manage iSCSI protocol

= Configure your network for best performance

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Ethernet networks vary greatly in performance. You can maximize the performance of the network used for iSCSI by selecting specific configuration values.

Steps

1. Connect the host and storage ports to the same network.

It is best to connect to the same switches. Routing should never be used.

2. Select the highest speed ports available, and dedicate them to iSCSI.

10 GbE ports are best. 1 GbE ports are the minimum.

3. Disable Ethernet flow control for all ports.

You should see the *ONTAP 9 Network Management Guide* for using the CLI to configure Ethernet port flow control.

Network management

4. Enable jumbo frames (typically MTU of 9000).

All devices in the data path, including initiators, targets, and switches, must support jumbo frames. Otherwise, enabling jumbo frames actually reduces network performance substantially.

= Define a security policy method for an initiator

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can define a list of initiators and their authentication methods. You can also modify the default authentication method that applies to initiators that do not have a user-defined authentication method.

About this task

You can generate unique passwords using security policy algorithms in the product or you can manually specify the passwords that you want to use.

Not all initiators support hexadecimal CHAP secret passwords.

Steps

1. Use the `vserver iscsi security create` command to create a security policy method for an initiator.

```
vserver iscsi security create -vserver vs2 -initiator iqn.1991-05.com.microsoft:host1 -auth-type CHAP -user-name bob1 -outbound-user-name bob2
```

2. Follow the screen commands to add the passwords.

Creates a security policy method for initiator iqn.1991-05.com.microsoft:host1 with inbound and outbound CHAP user names and passwords.

- [Guidelines for using CHAP authentication](#)
- [What CHAP authentication is](#)

= Delete an iSCSI service for an SVM

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can delete an iSCSI service for a storage virtual machine (SVM) if it is no longer required.

What you'll need

The administration status of the iSCSI service must be in the “down” state before you can delete an iSCSI service. You can move the administration status to down with the `vserver iscsi modify` command.

Steps

1. Use the `vserver iscsi modify` command to stop the I/O to the LUN.

```
vserver iscsi modify -vserver vs1 -status-admin down
```

2. Use the `vserver iscsi delete` command to remove the iscsi service from the SVM.

```
vserver iscsi delete -vserver vs_1
```

3. Use the vserver iscsi show command to verify that you deleted the iSCSI service from the SVM.

```
vserver iscsi show -vserver vs1
```

= Get more details in iSCSI session error recoveries

```
:icons: font  
:relative_path: ./san-admin/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

Increasing the iSCSI session error recovery level enables you to receive more detailed information about iSCSI error recoveries. Using a higher error recovery level might cause a minor reduction in iSCSI session performance.

About this task

By default, ONTAP is configured to use error recovery level 0 for iSCSI sessions. If you are using an initiator that has been qualified for error recovery level 1 or 2, you can choose to increase the error recovery level. The modified session error recovery level affects only the newly created sessions and does not affect existing sessions.

Beginning with ONTAP 9.4, the max-error-recovery-level option is not supported in the iscsi show and iscsi modify commands.

Steps

1. Enter advanced mode:

```
set -privilege advanced
```

2. Verify the current setting by using the iscsi show command.

```
iscsi show -vserver vs3 -fields max-error-recovery-level
```

```
vserver max-error-recovery-level  
-----  
vs3      0
```

3. Change the error recovery level by using the iscsi modify command.

```
iscsi modify -vserver vs3 -max-error-recovery-level 2
```

= Register the SVM with an iSNS server

```
:icons: font  
:relative_path: ./san-admin/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

You can use the vserver iscsi isns command to configure the storage virtual machine (SVM) to register with an iSNS server.

About this task

The vserver iscsi isns create command configures the SVM to register with the iSNS server. The SVM does not provide commands that enable you to configure or manage the iSNS server. To manage the iSNS server, you can use the server administration tools or the interface provided by the vendor for the iSNS server.

Steps

1. On your iSNS server, ensure that your iSNS service is up and available for service.
2. Create the SVM management LIF on a data port:

```
network interface create -vserver SVM_name -lif lif_name -role data -data  
-protocol none -home-node home_node_name -home-port home_port -address  
IP_address -netmask network_mask
```

3. Create an iSCSI service on your SVM if one does not already exist:

```
vserver iscsi create -vserver SVM_name
```

4. Verify that the iSCSI service was created successfully:

```
iscsi show -vserver SVM_name
```

5. Verify that a default route exists for the SVM:

```
network route show -vserver SVM_name
```

6. If a default route does not exist for the SVM, create a default route:

```
network route create -vserver SVM_name -destination destination -gateway  
gateway
```

7. Configure the SVM to register with the iSNS service:

```
vserver iscsi isns create -vserver SVM_name -address IP_address
```

Both IPv4 and IPv6 address families are supported. The address family of the iSNS server must be the same as that of the SVM management LIF.

For example, you cannot connect an SVM management LIF with an IPv4 address to an iSNS server with an IPv6 address.

8. Verify that the iSNS service is running:

```
vserver iscsi isns show -vserver SVM_name
```

9. If the iSNS service is not running, start it:

```
vserver iscsi isns start -vserver SVM_name
```

= Resolve iSCSI error messages on the storage system

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

There are a number of common iSCSI-related error messages that you can view with the `event log show` command. You need to know what these messages mean and what you can do to resolve the issues they identify.

The following table contains the most common error messages, and instructions for resolving them:

Message	Explanation	What to do
iSCSI: network interface identifier disabled for use; incoming connection discarded	The iSCSI service is not enabled on the interface.	You can use the <code>iscsi interface enable</code> command to enable the iSCSI service on the interface. For example: <code>iscsi interface enable -vserver vs1 -lif lif1</code>
iSCSI: Authentication failed for initiator nodename	CHAP is not configured correctly for the specified initiator.	You should check the CHAP settings; you cannot use the same user name and password for inbound and outbound settings on the storage system: <ul style="list-style-type: none"> Inbound credentials on the storage system must match outbound credentials on the initiator. Outbound credentials on the storage system must match inbound credentials on the initiator.

= Troubleshoot iSCSI LUNs not visible on the host

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The iSCSI LUNs appear as local disks to the host. If the storage system LUNs are not available as disks on the host, you should verify the configuration settings.

Configuration setting	What to do
Cabling	Verify that the cables between the host and storage system are properly connected.

Configuration setting	What to do
Network connectivity	<p>Verify that there is TCP/IP connectivity between the host and storage system.</p> <ul style="list-style-type: none"> From the storage system command line, ping the host interfaces that are being used for iSCSI: <pre>ping -node <i>node_name</i> -destination <i>host_ip_address_for_iSCSI</i></pre> <ul style="list-style-type: none"> From the host command line, ping the storage system interfaces that are being used for iSCSI: <pre>ping -node <i>node_name</i> -destination <i>host_ip_address_for_iSCSI</i></pre>
System requirements	Verify that the components of your configuration are qualified. Also, verify that you have the correct host operating system (OS) service pack level, initiator version, ONTAP version, and other system requirements. The Interoperability Matrix contains the most up-to-date system requirements.
Jumbo frames	If you are using jumbo frames in your configuration, verify that jumbo frames are enabled on all devices in the network path: the host Ethernet NIC, the storage system, and any switches.
iSCSI service status	Verify that the iSCSI service is licensed and started on the storage system.
Initiator login	Verify that the initiator is logged in to the storage system. If the <code>iscsi initiator show</code> command output shows no initiators are logged in, check the initiator configuration on the host. Also verify that the storage system is configured as a target of the initiator.
iSCSI node names (IQNs)	Verify that you are using the correct initiator node names in the igroup configuration. On the host, you can use the initiator tools and commands to display the initiator node name. The initiator node names configured in the igroup and on the host must match.
LUN mappings	<p>Verify that the LUNs are mapped to an igroup. On the storage system console, you can use one of the following commands:</p> <ul style="list-style-type: none"> <code>lun mapping show</code> displays all LUNs and the igroups to which they are mapped. <code>lun mapping show -igroup</code> displays the LUNs mapped to a specific igroup.
iSCSI LIFs enable	Verify that the iSCSI logical interfaces are enabled.

= Manage FC protocol

= Delete an FC service for an SVM

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can delete an FC service for a storage virtual machine (SVM) if it is no longer required.

What you'll need

The administration status must be “down” before you can delete a FC service for an SVM. You can set the administration status to down with either the `vserver fcp modify` command or the `vserver fcp stop` command.

Steps

1. Use the `vserver fcp stop` command to stop the I/O to the LUN.

```
vserver fcp stop -vserver vs_1
```

2. Use the `vserver fcp delete` command to remove the service from the SVM.

```
vserver fcp delete -vserver vs_1
```

3. Use the `vserver fcp show` to verify that you deleted the FC service from your SVM:

```
vserver fcp show -vserver vs_1
```

= Recommended MTU configurations for FCoE jumbo frames

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

For Fibre Channel over Ethernet (FCoE), jumbo frames for the Ethernet adapter portion of the CNA should be configured at 9000 MTU. Jumbo frames for the FCoE adapter portion of the CNA should be configured at greater than 1500 MTU. Only configure jumbo frames if the initiator, target, and all intervening switches support and are configured for jumbo frames.

= Manage systems with FC adapters

= Manage systems with FC adapters

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Commands are available to manage onboard FC adapters and FC adapter cards. These commands can be used to configure the adapter mode, display adapter information, and change the speed.

Most storage systems have onboard FC adapters that can be configured as initiators or targets. You can

also use FC adapter cards configured as initiators or targets. Initiators connect to back-end disk shelves, and possibly foreign storage arrays (FlexArray). Targets connect only to FC switches. Both the FC target HBA ports and the switch port speed should be set to the same value and should not be set to auto.

= Commands for managing FC adapters

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can use FC commands to manage FC target adapters, FC initiator adapters, and onboard FC adapters for your storage controller. The same commands are used to manage FC adapters for the FC protocol and the FC-NVMe protocol.

FC initiator adapter commands work only at the node level. You must use the `run -node node_name` command before you can use the FC initiator adapter commands.

== Commands for managing FC target adapters

If you want to...	Use this command...
Display FC adapter information on a node	<code>network fcp adapter show</code>
Modify FC target adapter parameters	<code>network fcp adapter modify</code>
Display FC protocol traffic information	<code>run -node node_name sysstat -f</code>
Display how long the FC protocol has been running	<code>run -node node_name uptime</code>
Display adapter configuration and status	<code>run -node node_name sysconfig -v adapter</code>
Verify which expansion cards are installed and whether there are any configuration errors	<code>run -node node_name sysconfig -ac</code>
View a man page for a command	<code>man command_name</code>

== Commands for managing FC initiator adapters

If you want to...	Use this command...
Display information for all initiators and their adapters in a node	<code>run -node node_name storage show adapter</code>
Display adapter configuration and status	<code>run -node node_name sysconfig -v adapter</code>

If you want to...	Use this command...
Verify which expansion cards are installed and whether there are any configuration errors	run -node <i>node_name</i> sysconfig -ac

== Commands for managing onboard FC adapters

If you want to...	Use this command...
Display the status of the onboard FC ports	run -node <i>node_name</i> system hardware unified-connect show

= Configure FC adapters for initiator mode

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can configure individual FC ports of onboard adapters and certain FC adapter cards for initiator mode. Initiator mode is used to connect the ports to tape drives, tape libraries, or third-party storage with FlexArray Virtualization or Foreign LUN Import (FLI).

What you'll need

- LIFs on the adapter must be removed from any port sets of which they are members.
- All LIF's from every storage virtual machine (SVM) using the physical port to be modified must be migrated or destroyed before changing the personality of the physical port from target to initiator.

About this task

Each onboard FC port can be individually configured as an initiator or a target. Ports on certain FC adapters can also be individually configured as either a target port or an initiator port, just like the onboard FC ports. A list of adapters that can be configured for target mode is available in the *Hardware Universe*.

NVMe/FC does support initiator mode.

Steps

1. Remove all LIFs from the adapter:

```
network interface delete -vserver SVM_name -lif LIF_name,LIF_name
```

2. Take your adapter offline:

```
network fcp adapter modify -node node_name -adapter adapter_port -status -admin down
```

If the adapter does not go offline, you can also remove the cable from the appropriate adapter port on the system.

3. Change the adapter from target to initiator:

```
system hardware unified-connect modify -t initiator adapter_port
```

4. Reboot the node hosting the adapter you changed.
5. Verify that the FC ports are configured in the correct state for your configuration:

```
system hardware unified-connect show
```

6. Bring the adapter back online:

```
node run -node node_name storage enable adapter adapter_port
```

Related information

[NetApp Hardware Universe](#)

= Configure FC adapters for target mode
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can configure individual FC ports of onboard adapters and certain FC adapter cards for target mode. Target mode is used to connect the ports to FC initiators.

About this task

Each onboard FC port can be individually configured as an initiator or a target. Ports on certain FC adapters can also be individually configured as either a target port or an initiator port, just like the onboard FC ports. A list of adapters that can be configured for target mode is available in the [NetApp Hardware Universe](#).

The same steps are used when configuring FC adapters for the FC protocol and the FC-NVMe protocol. However, only certain FC adapters support FC-NVMe. See the [NetApp Hardware Universe](#) for a list of adapters that support the FC-NVMe protocol.

Steps

1. Take the adapter offline:

```
node run -node node_name storage disable adapter adapter_name
```

If the adapter does not go offline, you can also remove the cable from the appropriate adapter port on the system.

2. Change the adapter from initiator to target:

```
system hardware unified-connect modify -t target -node node_name adapter adapter_name
```

3. Reboot the node hosting the adapter you changed.
4. Verify that the target port has the correct configuration:

```
network fcp adapter show -node node_name
```

5. Bring your adapter online:

```
network fcp adapter modify -node node_name -adapter adapter_port -state up
```

= Display information about an FC target adapter
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can use the `network fcp adapter show` command to display system configuration and adapter information for any FC adapter in the system.

Step

1. Display information about the FC adapter by using the `network fcp adapter show` command.

The output displays system configuration information and adapter information for each slot that is used.

```
network fcp adapter show -instance -node node1 -adapter 0a
```

= Change the UTA2 port from CNA mode to FC mode
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You should change the UTA2 port from Converged Network Adapter (CNA) mode to Fibre Channel (FC) mode to support the FC initiator and FC target mode. You should change the personality from CNA mode to FC mode when you need to change the physical medium that connects the port to its network.

Steps

1. Take the adapter offline:

```
network fcp adapter modify -node node_name -adapter adapter_name -status  
-admin down
```

2. Change the port mode:

```
ucadmin modify -node node_name -adapter adapter_name -mode fcp
```

3. Reboot the node, and then bring the adapter online:

```
network fcp adapter modify -node node_name -adapter adapter_name -status  
-admin up
```

4. Notify your admin or VIF manager to delete or remove the port, as applicable:

- If the port is used as a home port of a LIF, is a member of an interface group (ifgrp), or hosts VLANs, then an admin should do the following:

- i. Move the LIFs, remove the port from the ifgrp, or delete the VLANs, respectively.
- ii. Manually delete the port by running the `network port delete` command.

If the `network port delete` command fails, the admin should address the errors, and then run the command again.

- If the port is not used as the home port of a LIF, is not a member of an ifgrp, and does not host VLANs, then the VIF manager should remove the port from its records at the time of reboot.

If the VIF manager does not remove the port, then the admin must remove it manually after the reboot by using the `network port delete` command.

```

Warning: Mode on adapter 0e and also adapter 0f will be changed to fc.

Do you want to continue? {y|n}: y

Any changes will take effect after rebooting the system. Use the "system node reboot" command to reboot.

```
net-f8040-34::> reboot local
    (system node reboot)
```

Warning: Are you sure you want to reboot node "net-f8040-34-01"?
{y|n}: y

5. Verify that you have the correct SFP+ installed:

```
network fcp adapter show -instance -node -adapter
```

For CNA, you should use a 10Gb Ethernet SFP. For FC, you should either use an 8 Gb SFP or a 16 Gb SFP, before changing the configuration on the node.

= Change the CNA/UTA2 target adapter optical modules
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You should change the optical modules on the unified target adapter (CNA/UTA2) to support the personality mode you have selected for the adapter.

Steps

1. Verify the current SFP+ used in the card. Then, replace the current SFP+ with the appropriate SFP+ for the preferred personality (FC or CNA).
2. Remove the current optical modules from the X1143A-R6 adapter.
3. Insert the correct modules for your preferred personality mode (FC or CNA) optics.
4. Verify that you have the correct SFP+ installed:

```
network fcp adapter show -instance -node -adapter
```

Supported SFP+ modules and Cisco-branded Copper (Twinax) cables are listed in the *Hardware Universe*.

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

To view the settings for your unified target adapter (X1143A-R6), you must run the system hardware unified-connect show command to display all modules on your controller.

Steps

1. Boot your controller without the cables attached.
2. Run the system hardware unified-connect show command to see the port configuration and modules.
3. View the port information before configuring the CNA and ports.

= Supported port configurations for X1143A-R6 adapters

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The FC target mode is the default configuration for X1143A-R6 adapter ports. However, ports on this adapter can be configured as either 10-Gb Ethernet and FCoE ports or as 16-Gb FC ports.

When configured for Ethernet and FCoE, X1143A-R6 adapters support concurrent NIC and FCoE target traffic on the same 10-GBE port. When configured for FC, each two-port pair that shares the same ASIC can be individually configured for FC target or FC initiator mode. This means that a single X1143A-R6 adapter can support FC target mode on one two-port pair and FC initiator mode on another two-port pair.

[NetApp Hardware Universe](#)

[SAN configuration](#)

= Configure the ports

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

To configure the unified target adapter (X1143A-R6), you must configure the two adjacent ports on the same chip in the same personality mode.

Steps

1. Configure the ports as needed for Fibre Channel (FC) or Converged Network Adapter (CNA) using

the system node hardware unified-connect modify command.

2. Attach the appropriate cables for FC or 10 Gb Ethernet.
3. Verify that you have the correct SFP+ installed:

```
network fcp adapter show -instance -node -adapter
```

For CNA, you should use a 10Gb Ethernet SFP. For FC, you should either use an 8 Gb SFP or a 16 Gb SFP, based on the FC fabric being connected to.

= Prevent loss of connectivity when using the X1133A-R6 adapter
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can prevent loss of connectivity during a port failure by configuring your system with redundant paths to separate X1133A-R6 HBAs.

The X1133A-R6 HBA is a 4-port, 16 Gb FC adapter consisting of two 2-port pairs. The X1133A-R6 adapter can be configured as target mode or initiator mode. Each 2-port pair is supported by a single ASIC (for example, Port 1 and Port 2 on ASIC 1 and Port 3 and Port 4 on ASIC 2). Both ports on a single ASIC must be configured to operate in the same mode, either target mode or initiator mode. If an error occurs with the ASIC supporting a pair, both ports in the pair go offline.

To prevent this loss of connectivity, you configure your system with redundant paths to separate X1133A-R6 HBAs, or with redundant paths to ports supported by different ASICs on the HBA.

= Manage NVMe protocol

= Manage NVMe
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Beginning with ONTAP 9.4, NVMe/FC is supported. Beginning with ONTAP 9.5 a license is required to support NVMe. If NVMe is enabled in ONTAP 9.4, a 90 day grace period is given to acquire the license after upgrading to ONTAP 9.5.

You can enable the license using the following command:

```
system license add -license-code NVMe_license_key
```

= Start the NVMe service for an SVM
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Before you can use the NVMe protocol on your storage virtual machine (SVM), you must start the NVMe service on the SVM.

What you'll need

NVMe must be allowed as a protocol on your system.

The following NVMe protocols are supported:

Protocol	Beginning with...	Allowed by...
TCP	ONTAP 9.10.1	Default
FCP	ONTAP 9.4	Default

Steps

1. Change the privilege setting to advanced:

```
set -privilege advanced
```

2. Verify that NVMe is allowed as a protocol:

```
vserver nvme show
```

3. Create the NVMe protocol service:

```
vserver nvme create
```

4. Start the NVMe protocol service on the SVM:

```
vserver nvme modify -status -admin up
```

= Delete NVMe service from an SVM

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If needed, you can delete the NVMe service from your storage virtual machine (SVM).

Steps

1. Change the privilege setting to advanced:

```
set -privilege advanced
```

2. Stop the NVMe service on the SVM:

```
vserver nvme modify -status -admin down
```

3. Delete the NVMe service:

```
vserver nvme delete
```

= Manage LIFs for all SAN protocols

= Manage LIFs for all SAN protocols

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

LIFs are connected to the SAN hosts. They can be removed from port sets, moved to different nodes within a storage virtual machine (SVM), and deleted.

Related information

[Network management](#)

= Configure an NVMe LIF

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Certain requirements must be met when configuring NVMe LIFs.

What you'll need

NVMe must be supported by the FC adapter on which you create the LIF. Supported adapters are listed in the *Hardware Universe*.

[NetApp Hardware Universe](#)

About this task

The following rules apply when creating an NVMe LIF:

- NVMe can be the only data protocol on data LIFs.
- You should configure one management LIF for every SVM that supports SAN.
- For ONTAP 9.5 and later:
 - You can only configure two NVMe LIFs per node on a maximum of four nodes.
 - You must configure an NVMe LIF on the node containing the namespace and on node's HA partner.
- For ONTAP 9.4 only:
 - NVMe LIFs and namespaces must be hosted on the same node.
 - Only one NVMe data LIF can be configured per SVM.

Steps

1. Create the LIF:

```
network interface create -vserver SVM_name -lif LIF_name -role LIF_role  
-data-protocol fc-nvme -home-node home_node -home-port  
home_port
```

2. Verify that the LIF was created:

```
network interface show -vserver SVM_name
```

= Considerations for SAN LIF movement

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You only need to perform a LIF movement if you are changing the contents of your cluster, for example, adding nodes to the cluster or deleting nodes from the cluster. If you perform a LIF movement, you do not have to re-zone your FC fabric or create new iSCSI sessions between the attached hosts of your cluster and the new target interface.

You cannot move a SAN LIF using the `network interface move` command. SAN LIF movement must be performed by taking the LIF offline, moving the LIF to a different home node or port, and then bringing it back online in its new location. Asymmetric Logical Unit Access (ALUA) provides redundant paths and automatic path selection as part of any ONTAP SAN solution. Therefore, there is no I/O interruption when the LIF is taken offline for the movement. The host simply retries and then moves I/O to another LIF.

Using LIF movement, you can nondisruptively do the following:

- Replace one HA pair of a cluster with an upgraded HA pair in a way that is transparent to hosts accessing LUN data
- Upgrade a target interface card
- Shift the resources of a storage virtual machine (SVM) from one set of nodes in a cluster to another set of nodes in the cluster

= Remove a SAN LIF from a port set

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If the LIF you want to delete or move is in a port set, you must remove the LIF from the port set before you can delete or move the LIF.

About this task

You need to do Step 1 in the following procedure only if one LIF is in the port set. You cannot remove the last LIF in a port set if the port set is bound to an initiator group. Otherwise, you can start with Step 2 if multiple LIFs are in the port set.

Steps

1. If only one LIF is in the port set, use the `lun igrup unbind` command to unbind the port set from the initiator group.

When you unbind an initiator group from a port set, all of the initiators in the initiator group have access to all target LUNs mapped to the initiator group on all network interfaces.

```
cluster1::>lun igrup unbind -vserver vs1 -igroup ig1
```

2. Use the `lun portset remove` command to remove the LIF from the port set.

```
cluster1::> port set remove -vserver vs1 -portset ps1 -port-name lif1
```

= Move a SAN LIF

:icons: font

:relative_path: ./san-admin/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

If a node needs to be taken offline, you can move a SAN LIF to preserve its configuration information, such as its WWPN, and avoid rezoning the switch fabric. Because a SAN LIF must be taken offline before it is moved, host traffic must rely on host multipathing software to provide nondisruptive access to the LUN. You can move SAN LIFs to any node in a cluster, but you cannot move the SAN LIFs between storage virtual machines (SVMs).

What you'll need

If the LIF is a member of a port set, the LIF must have been removed from the port set before the LIF can be moved to a different node.

About this task

The destination node and physical port for a LIF that you want to move must be on the same FC fabric or Ethernet network. If you move a LIF to a different fabric that has not been properly zoned, or if you move a LIF to an Ethernet network that does not have connectivity between iSCSI initiator and target, the LUN will be inaccessible when you bring it back online.

Steps

1. View the administrative and operational status of the LIF:

```
network interface show -vserver vserver_name
```

2. Change the status of the LIF to down (offline):

```
network interface modify -vserver vserver_name -lif LIF_name -status-admin  
down
```

3. Assign the LIF a new node and port:

```
network interface modify -vserver vserver_name -lif LIF_name -home-node  
node_name -home-port port_name
```

4. Change the status of the LIF to up (online):

```
network interface modify -vserver vserver_name -lif LIF_name -status-admin  
up
```

5. Verify your changes:

```
network interface show -vserver vserver_name
```

= Delete a LIF in a SAN environment

:icons: font

:relative_path: ./san-admin/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

Before you delete a LIF, you should ensure that the host connected to the LIF can access the LUNs through another path.

What you'll need

If the LIF you want to delete is a member of a port set, you must first remove the LIF from the port set before you can delete the LIF.

Steps

1. Verify the name of the LIF and current port to be deleted:

```
network interface show -vserver vserver_name
```

2. Delete the LIF:

```
network interface delete
```

```
network interface delete -vserver vs1 -lif lif1
```

3. Verify that you deleted the LIF:

```
network interface show
```

```
network interface show -vserver vs1
```

Logical Vserver	Status Interface	Network Admin/Oper	Address/Mask	Current Node	Current Port	Is
Home						
-----	-----	-----	-----	-----	-----	-----

vs1						
-----	-----	-----	-----	-----	-----	-----
true	lif2	up/up	192.168.2.72/24	node-01	e0b	
true	lif3	up/up	192.168.2.73/24	node-01	e0b	

= Considerations for adding nodes to a cluster

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You need to be aware of certain considerations when adding nodes to a cluster.

- You must create LIFs on the new nodes as appropriate before you create LUNs on those new nodes.
- You must discover those LIFs from the hosts as dictated by the host stack and protocol.
- You must create LIFs on the new nodes so that the LUN and volume movements are possible without using the cluster interconnect network.

= Configure iSCSI LIFs to return FQDN to host iSCSI SendTargets Discovery Operation

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Beginning with ONTAP 9, iSCSI LIFs can be configured to return a Fully Qualified Domain Name (FQDN) when a host OS sends an iSCSI SendTargets Discovery Operation. Returning a FQDN is useful when there is a Network Address Translation (NAT) device between the host OS and the storage service.

About this task

IP addresses on one side of the NAT device are meaningless on the other side, but FQDNs can have meaning on both sides.

The FQDN value interoperability limit is 128 characters on all host OS.

Steps

1. Change the privilege setting to advanced:

```
set -privilege advanced
```

2. Configure iSCSI LIFs to return FQDN:

```
vserver iscsi interface modify -vserver SVM_name -lif iscsi_LIF_name  
-sendtargets_fqdn FQDN
```

In the following example, the iSCSI LIFs are configured to return storagehost-005.example.com as the FQDN.

```
vserver iscsi interface modify -vserver vs1 -lif vs1_iscsil -sendtargets  
-fqdn storagehost-005.example.com
```

3. Verify that sendtargets is the FQDN:

```
vserver iscsi interface show -vserver SVM_name -fields sendtargets-fqdn
```

In this example, storagehost-005.example.com is displayed in the sendtargets-fqdn output field.

```
cluster::vserver*> vserver iscsi interface show -vserver vs1 -fields  
sendtargets-fqdn  
vserver lif          sendtargets-fqdn  
-----  
vs1      vs1_iscsil storagehost-005.example.com  
vs1      vs1_iscsi2 storagehost-006.example.com
```

ONTAP 9 commands

= Data protection methods in SAN environments

= Data protection methods in SAN environments overview

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can protect your data by making copies of it so that it is available for restoration in the event of accidental deletion, application crashes, data corruption, or disaster. Depending on your data protection and backup needs, ONTAP offers a variety of methods that enable you to protect your data.

== SnapMirror Business Continuity (SM-BC)

Beginning with general availability in ONTAP 9.9.1, provides Zero Recovery Time Objective (Zero RTO) or Transparent Application Failover (TAF) to enable automatic failover of business-critical applications in SAN environments. SM-BC requires the installation of ONTAP Mediator 1.2 in a configuration with either two AFF clusters or two All SAN Array (ASA) clusters.

[NetApp Documentation: SnapMirror Business Continuity](#)

== Snapshot copy

Enables you to manually or automatically create, schedule, and maintain multiple backups of your LUNs. Snapshot copies use only a minimal amount of additional volume space and do not have a performance cost. If your LUN data is accidentally modified or deleted, that data can easily and quickly be restored from one of the latest Snapshot copies.

== FlexClone LUNs (FlexClone license required)

Provides point-in-time, writable copies of another LUN in an active volume or in a Snapshot copy. A clone and its parent can be modified independently without affecting each other.

== SnapRestore (license required)

Enables you to perform fast, space-efficient, on-request data recovery from Snapshot copies on an entire volume. You can use SnapRestore to restore a LUN to an earlier preserved state without rebooting the storage system.

== Data protection mirror copies (SnapMirror license required)

Provides asynchronous disaster recovery by enabling you to periodically create Snapshot copies of data on your volume; copy those Snapshot copies over a local or wide area network to a partner volume, usually on another cluster; and retain those Snapshot copies. The mirror copy on the partner volume provides quick availability and restoration of data from the time of the last Snapshot copy, if the data on the source volume is corrupted or lost.

== SnapVault backups (SnapMirror license required)

Provides storage efficient and long-term retention of backups. SnapVault relationships enable you to back up selected Snapshot copies of volumes to a destination volume and retain the backups.

If you conduct tape backups and archival operations, you can perform them on the data that is already backed up on the SnapVault secondary volume.

== SnapDrive for Windows or UNIX (SnapDrive license required)

Configures access to LUNs, manages LUNs, and manages storage system Snapshot copies directly from a Windows or UNIX hosts.

== Native tape backup and recovery

Support for most existing tape drives are included in ONTAP, as well as a method for tape vendors to dynamically add support for new devices. ONTAP also supports the Remote Magnetic Tape (RMT) protocol, enabling backup and recovery to any capable system.

[Data protection using tape backup](#)

= Effect of moving or copying a LUN on Snapshot copies

= Effect of moving or copying a LUN on Snapshot copies overview

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Snapshot copies are created at the volume level. If you copy or move a LUN to a different volume, the Snapshot copy policy of the destination volume is applied to the copied or moved volume. If Snapshot copies are not established for the destination volume, Snapshot copies will not be created of the moved or copied LUN.

= Restore a single LUN from a Snapshot copy

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can restore a single LUN from a Snapshot copy without restoring the entire volume that contains the single LUN. You can restore the LUN in place or to a new path in the volume. The operation restores only the single LUN without impacting other files or LUNs in the volume. You can also restore files with streams.

What you'll need

- You must have enough space on your volume to complete the restore operation:
 - If you are restoring a space-reserved LUN where the fractional reserve is 0%, you require one times the size of the restored LUN.
 - If you are restoring a space-reserved LUN where the fractional reserve is 100%, you require two times the size of the restored LUN.
 - If you are restoring a non-space-reserved LUN, you only require the actual space used for the restored LUN.
- A Snapshot copy of the destination LUN must have been created.

If the restore operation fails, the destination LUN might be truncated. In such cases, you can use the Snapshot copy to prevent data loss.

- A Snapshot copy of the source LUN must have been created.

In rare cases, the LUN restore can fail, leaving the source LUN unusable. If this occurs, you can use the Snapshot copy to return the LUN to the state just before the restore attempt.

- The destination LUN and source LUN must have the same OS type.

If your destination LUN has a different OS type from your source LUN, your host can lose data access to the destination LUN after the restore operation.

Steps

1. From the host, stop all host access to the LUN.
2. Unmount the LUN on its host so that the host cannot access the LUN.
3. Unmap the LUN:

```
lun mapping delete -vserver vserver_name -volume volume_name -lun lun_name
-igroup igrup_name
```

4. Determine the Snapshot copy you want to restore your LUN to:

```
volume snapshot show -vserver vserver_name -volume volume_name
```

5. Create a Snapshot copy of the LUN prior to restoring the LUN:

```
volume snapshot create -vserver vserver_name -volume volume_name -snapshot
snapshot_name
```

6. Restore the specified LUN in a volume:

```
volume snapshot restore-file -vserver vserver_name -volume volume_name
-snapshot snapshot_name -path lun_path
```

7. Follow the steps on the screen.

8. If necessary, bring the LUN online:

```
lun modify -vserver vserver_name -path lun_path -state online
```

9. If necessary, remap the LUN:

```
lun mapping create -vserver vserver_name -volume volume_name -lun lun_name
-igroup igrup_name
```

10. From the host, remount the LUN.

11. From the host, restart access to the LUN.

= Restore all LUNs in a volume from a Snapshot copy

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

You can use `volume snapshot restore` command to restore all the LUNs in a specified volume from a Snapshot copy.

Steps

1. From the host, stop all host access to the LUNs.

Using SnapRestore without stopping all host access to LUNs in the volume can cause data corruption and system errors.

2. Unmount the LUNs on that host so that the host cannot access the LUNs.

3. Unmap your LUNs:

```
lun mapping delete -vserver vserver_name -volume volume_name -lun lun_name  
-igroup igrup_name
```

4. Determine the Snapshot copy to which you want to restore your volume:

```
volume snapshot show -vserver vserver_name -volume volume_name
```

5. Change your privilege setting to advanced:

```
set -privilege advanced
```

6. Restore your data:

```
volume snapshot restore -vserver vserver_name -volume volume_name -snapshot  
snapshot_name
```

7. Follow the instructions on the screen.

8. Remap your LUNs:

```
lun mapping create -vserver vserver_name -volume volume_name -lun lun_name  
-igroup igrup_name
```

9. Verify that your LUNs are online:

```
lun show -vserver vserver_name -path lun_path -fields state
```

10. If your LUNs are not online, bring them online:

```
lun modify -vserver vserver_name -path lun_path -state online
```

11. Change your privilege setting to admin:

```
set -privilege admin
```

12. From the host, remount your LUNs.

13. From the host, restart access to your LUNs.

= Delete one or more existing Snapshot copies from a volume

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can manually delete one or more existing Snapshot copies from the volume. You might want to do this if you need more space on your volume.

Steps

1. Use the `volume snapshot show` command to verify which Snapshot copies you want to delete.

```
cluster::> volume snapshot show -vserver vs3 -volume vol3

                                         ---Blocks---
Vserver   Volume   Snapshot           Size   Total% Used%
-----  -----  -----
vs3       vol3
          snap1.2013-05-01_0015    100KB   0%   38%
          snap1.2013-05-08_0015    76KB    0%   32%
          snap2.2013-05-09_0010    76KB    0%   32%
          snap2.2013-05-10_0010    76KB    0%   32%
          snap3.2013-05-10_1005    72KB    0%   31%
          snap3.2013-05-10_1105    72KB    0%   31%
          snap3.2013-05-10_1205    72KB    0%   31%
          snap3.2013-05-10_1305    72KB    0%   31%
          snap3.2013-05-10_1405    72KB    0%   31%
          snap3.2013-05-10_1505    72KB    0%   31%
10 entries were displayed.
```

2. Use the `volume snapshot delete` command to delete all of the Snapshot copies.

```
cluster::> volume snapshot delete -vserver vs3 -volume vol3 *

10 entries were acted on.
```

= Use FlexClone LUNs to protect your data

= Use FlexClone LUNs to protect your data overview

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

A FlexClone LUN is a point-in-time, writeable copy of another LUN in an active volume or in a Snapshot copy. The clone and its parent can be modified independently without affecting each other.

A FlexClone LUN shares space initially with its parent LUN. By default, the FlexClone LUN inherits the space-reserved attribute of the parent LUN. For example, if the parent LUN is non-space-reserved, the FlexClone LUN is also non-space-reserved by default. However, you can create a non-space-reserved FlexClone LUN from a parent that is a space-reserved LUN.

When you clone a LUN, block sharing occurs in the background and you cannot create a volume Snapshot copy until the block sharing is finished.

You must configure the volume to enable the FlexClone LUN automatic deletion function with the `volume`

`snapshot autodelete modify` command. Otherwise, if you want FlexClone LUNs to be deleted automatically but the volume is not configured for FlexClone auto delete, none of the FlexClone LUNs are deleted.

When you create a FlexClone LUN, the FlexClone LUN automatic deletion function is disabled by default. You must manually enable it on every FlexClone LUN before that FlexClone LUN can be automatically deleted. If you are using semi-thick volume provisioning and you want the “best effort” write guarantee provided by this option, you must make *all* FlexClone LUNs available for automatic deletion.

 When you create a FlexClone LUN from a Snapshot copy, the LUN is automatically split from the Snapshot copy by using a space-efficient background process so that the LUN does not continue to depend on the Snapshot copy or consume any additional space. If this background split has not been completed and this Snapshot copy is automatically deleted, that FlexClone LUN is deleted even if you have disabled the FlexClone auto delete function for that FlexClone LUN. After the background split is complete, the FlexClone LUN is not deleted even if that Snapshot copy is deleted.

Related information

[Logical storage management](#)

= Reasons for using FlexClone LUNs

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can use FlexClone LUNs to create multiple read/write copies of a LUN.

You might want to do this for the following reasons:

- You need to create a temporary copy of a LUN for testing purposes.
- You need to make a copy of your data available to additional users without giving them access to the production data.
- You want to create a clone of a database for manipulation and projection operations, while preserving the original data in an unaltered form.
- You want to access a specific subset of a LUN’s data (a specific logical volume or file system in a volume group, or a specific file or set of files in a file system) and copy it to the original LUN, without restoring the rest of the data in the original LUN. This works on operating systems that support mounting a LUN and a clone of the LUN at the same time. SnapDrive for UNIX supports this with the `snap connect` command.
- You need multiple SAN boot hosts with the same operating system.

= How a FlexVol volume can reclaim free space with autodelete setting

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can enable the autodelete setting of a FlexVol volume to automatically delete FlexClone files and FlexClone LUNs. By enabling autodelete, you can reclaim a target amount of free space in the volume when a volume is nearly full.

You can configure a volume to automatically start deleting FlexClone files and FlexClone LUNs when the

free space in the volume decreases below a particular threshold value, and automatically stop deleting clones when a target amount of free space in the volume is reclaimed. Although, you cannot specify the threshold value that starts the automatic deletion of clones, you can specify whether a clone is eligible for deletion, and you can specify the target amount of free space for a volume.

A volume automatically deletes FlexClone files and FlexClone LUNs when the free space in the volume decreases below a particular threshold and when *both* of the following requirements are met:

- The autodelete capability is enabled for the volume that contains the FlexClone files and FlexClone LUNs.

You can enable the autodelete capability for a FlexVol volume by using the `volume snapshot autodelete modify` command. You must set the `-trigger` parameter to `volume` or `snap_reserve` for a volume to automatically delete FlexClone files and FlexClone LUNs.

- The autodelete capability is enabled for the FlexClone files and FlexClone LUNs.

You can enable autodelete for a FlexClone file or FlexClone LUN by using the `file clone create` command with the `-autodelete` parameter. As a result, you can preserve certain FlexClone files and FlexClone LUNs by disabling autodelete for the clones and ensuring that other volume settings do not override the clone setting.

= Configure a FlexVol volume to automatically delete FlexClone files and FlexClone LUNs

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can enable a FlexVol volume to automatically delete FlexClone files and FlexClone LUNs with autodelete enabled when the free space in the volume decreases below a particular threshold.

What you'll need

- The FlexVol volume must contain FlexClone files and FlexClone LUNs and be online.
- The FlexVol volume must not be a read-only volume.

Steps

1. Enable automatic deletion of FlexClone files and FlexClone LUNs in the FlexVol volume by using the `volume snapshot autodelete modify` command.
 - For the `-trigger` parameter, you can specify `volume` or `snap_reserve`.
 - For the `-destroy-list` parameter, you must always specify `lun_clone, file_clone` regardless of whether you want to delete only one type of clone.

The following example shows how you can enable volume `vol1` to trigger the automatic deletion of FlexClone files and FlexClone LUNs for space reclamation until 25% of the volume consists of free space:

```
cluster1::> volume snapshot autodelete modify -vserver vs1  
-volume vol1 -enabled true -commitment disrupt -trigger volume  
-target-free-space 25 -destroy-list lun_clone,file_clone
```

```
Volume modify successful on volume:vol1
```

While enabling FlexVol volumes for automatic deletion, if you set the value of the `-commitment` parameter to `destroy`, all the FlexClone files and FlexClone LUNs with the `-autodelete` parameter set to `true` might be deleted when the free space in the volume decreases below the specified threshold value. However, FlexClone files and FlexClone LUNs with the `-autodelete` parameter set to `false` will not be deleted.

2. Verify that automatic deletion of FlexClone files and FlexClone LUNs is enabled in the FlexVol volume by using the `volume snapshot autodelete show` command.

The following example shows that volume `vol1` is enabled for automatic deletion of FlexClone files and FlexClone LUNs:

```
cluster1::> volume snapshot autodelete show -vserver vs1 -volume  
vol1
```

```
Vserver Name: vs1  
Volume Name: vol1  
Enabled: true  
Commitment: disrupt  
Defer Delete: user_created  
Delete Order: oldest_first  
Defer Delete Prefix: (not specified)*  
Target Free Space: 25%  
Trigger: volume  
Destroy List: lun_clone,file_clone  
Is Constituent Volume: false
```

3. Ensure that autodelete is enabled for the FlexClone files and FlexClone LUNs in the volume that you want to delete by performing the following steps:

- a. Enable automatic deletion of a particular FlexClone file or FlexClone LUN by using the `volume file clone autodelete` command.

You can force a specific FlexClone file or FlexClone LUN to be automatically deleted by using the `volume file clone autodelete` command with the `-force` parameter.

The following example shows that automatic deletion of the FlexClone LUN `lun1_clone` contained in volume `vol1` is enabled:

```
cluster1::> volume file clone autodelete -vserver vs1 -clone-path  
/vol/vol1/lun1_clone -enabled true
```

You can enable autodelete when you create FlexClone files and FlexClone LUNs.

- b. Verify that the FlexClone file or FlexClone LUN is enabled for automatic deletion by using the `volume file clone show-autodelete` command.

The following example shows that the FlexClone LUN `lun1_clone` is enabled for automatic deletion:

```
cluster1::> volume file clone show-autodelete -vserver vs1 -clone  
-path vol/vol1/lun1_clone  
  
Vserver Name: vs1  
Path: vol/vol1/lun1_clone  
  
**Autodelete Enabled: true**
```

For more information about using the commands, see the respective man pages.

= Clone LUNs from an active volume

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can create copies of your LUNs by cloning the LUNs in the active volume. These FlexClone LUNs are readable and writeable copies of the original LUNs in the active volume.

What you'll need

A FlexClone license must be installed.

About this task

A space-reserved FlexClone LUN requires as much space as the space-reserved parent LUN. If the FlexClone LUN is not space-reserved, you must ensure that the volume has enough space to accommodate changes to the FlexClone LUN.

Steps

1. You must have verified that the LUNs are not mapped to an igroup or are written to before making the clone.
2. Use the `lun show` command to verify that the LUN exists.

```
lun show -vserver vs1
```

Vserver	Path	State	Mapped	Type	Size
vs1	/vol/vol1/lun1	online	unmapped	windows	47.07MB

3. Use the `volume file clone create` command to create the FlexClone LUN.

```
volume file clone create -vserver vs1 -volume vol1 -source-path lun1
-destination-path/lun1_clone
```

If you need the FlexClone LUN to be available for automatic deletion, you include `-autodelete true`. If you are creating this FlexClone LUN in a volume using semi-thick provisioning, you must enable automatic deletion for all FlexClone LUNs.

4. Use the `lun show` command to verify that you created a LUN.

```
lun show -vserver vs1
```

Vserver	Path	State	Mapped	Type	Size
vs1	/vol/volX/lun1	online	unmapped	windows	47.07MB
vs1	/vol/volX/lun1_clone	online	unmapped	windows	47.07MB

= Create FlexClone LUNs from a Snapshot copy in a volume

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can use a Snapshot copy in your volume to create FlexClone copies of your LUNs. FlexClone copies of LUNs are both readable and writeable.

What you'll need

A FlexClone license must be installed.

About this task

The FlexClone LUN inherits the space reservations attribute of the parent LUN. A space-reserved FlexClone LUN requires as much space as the space-reserved parent LUN. If the FlexClone LUN is not space-reserved, the volume must have enough space to accommodate changes to the clone.

Steps

1. Verify that the LUN is not mapped or being written to.
2. Create a Snapshot copy of the volume that contains the LUNs:

```
volume snapshot create -vserver vserver_name -volume volume_name -snapshot
snapshot_name
```

You must create a Snapshot copy (the backing Snapshot copy) of the LUN you want to clone.

3. Create the FlexClone LUN from the Snapshot copy:

```
file clone create -vserver vserver_name -volume volume_name -source-path source_path -snapshot-name snapshot_name -destination-path destination_path
```

If you need the FlexClone LUN to be available for automatic deletion, you include `-autodelete true`. If you are creating this FlexClone LUN in a volume using semi-thick provisioning, you must enable automatic deletion for all FlexClone LUNs.

4. Verify that the FlexClone LUN is correct:

```
lun show -vserver vserver_name
```

Vserver	Path	State	Mapped	Type	Size
vs1	/vol/vol1/lun1_clone	online	unmapped	windows	47.07MB
vs1	/vol/vol1/lun1_snap_clone	online	unmapped	windows	47.07MB

= Prevent a specific FlexClone file or FlexClone LUN from being automatically deleted

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you configure a FlexVol volume to automatically delete FlexClone files and FlexClone LUNs, any clone that fits the criteria you specify might be deleted. If you have specific FlexClone files or FlexClone LUNs that you want to preserve, you can exclude them from the automatic FlexClone deletion process.

What you'll need

A FlexClone license must be installed.

About this task

When you create a FlexClone file or FlexClone LUN, by default the autodelete setting for the clone is disabled. FlexClone files and FlexClone LUNs with autodelete disabled are preserved when you configure a FlexVol volume to automatically delete clones to reclaim space on the volume.

 If you set the commitment level on the volume to `try` or `disrupt`, you can individually preserve specific FlexClone files or FlexClone LUNs by disabling autodelete for those clones. However, if you set the commitment level on the volume to `destroy` and the destroy lists include `lun_clone`, `file_clone`, the volume setting overrides the clone setting, and all FlexClone files and FlexClone LUNs can be deleted regardless of the autodelete setting for the clones.

Steps

1. Prevent a specific FlexClone file or FlexClone LUN from being automatically deleted by using the `volume file clone autodelete` command.

The following example shows how you can disable autodelete for FlexClone LUN lun1_clone contained in vol1:

```
cluster1::> volume file clone autodelete -vserver vs1 -volume vol1  
-clone-path lun1_clone -enable false
```

A FlexClone file or FlexClone LUN with autodelete disabled cannot be deleted automatically to reclaim space on the volume.

2. Verify that autodelete is disabled for the FlexClone file or FlexClone LUN by using the `volume file clone show-autodelete` command.

The following example shows that autodelete is false for the FlexClone LUN lun1_clone:

```
cluster1::> volume file clone show-autodelete -vserver vs1 -clone  
-path vol/vol1/lun1_clone  
Vserver  
Name: vs1  
Clone  
Path: vol/vol1/lun1_clone  
Autodelete Enabled: false
```

= Configure and use SnapVault backups in a SAN environment

= Configure and use SnapVault backups in a SAN environment overview

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

SnapVault configuration and use in a SAN environment is very similar to configuration and use in a NAS environment, but restoring LUNs in a SAN environment requires some special procedures.

SnapVault backups contain a set of read-only copies of a source volume. In a SAN environment you always back up entire volumes to the SnapVault secondary volume, not individual LUNs.

The procedure for creating and initializing the SnapVault relationship between a primary volume containing LUNs and a secondary volume acting as a SnapVault backup is identical to the procedure used with FlexVol volumes used for file protocols. This procedure is described in detail in [Data Protection](#).

Data protection

It is important to ensure that LUNs being backed up are in a consistent state before the Snapshot copies are created and copied to the SnapVault secondary volume. Automating the Snapshot copy creation with a product like SnapManager for Microsoft SQL Server ensures that backed up LUNs are complete and usable by the original application.

There are three basic choices for restoring LUNs from a SnapVault secondary volume:

- You can map a LUN directly from the SnapVault secondary volume and connect a host to the LUN to access the contents of the LUN.

The LUN is read-only and you can map only from the most recent Snapshot copy in the SnapVault backup. Persistent reservations and other LUN metadata are lost. If desired, you can use a copy program on the host to copy the LUN contents back to the original LUN if it is still accessible.

The LUN has a different serial number from the source LUN.

- You can clone any Snapshot copy in the SnapVault secondary volume to a new read-write volume.

You can then map any of the LUNs in the volume and connect a host to the LUN to access the contents of the LUN. If desired, you can use a copy program on the host to copy the LUN contents back to the original LUN if it is still accessible.

- You can restore the entire volume containing the LUN from any Snapshot copy in the SnapVault secondary volume.

Restoring the entire volume replaces all of the LUNs, and any files, in the volume. Any new LUNs created since the Snapshot copy was created are lost.

The LUNs retain their mapping, serial numbers, UUIDs, and persistent reservations.

= Access a read-only LUN copy from a SnapVault backup

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can access a read-only copy of a LUN from the latest Snapshot copy in a SnapVault backup. The LUN ID, path, and serial number are different from the source LUN and must first be mapped. Persistent reservations, LUN mappings, and igroups are not replicated to the SnapVault secondary volume.

What you'll need

- The SnapVault relationship must be initialized and the latest Snapshot copy in the SnapVault secondary volume must contain the desired LUN.
- The storage virtual machine (SVM) containing the SnapVault backup must have one or more LIFs with the desired SAN protocol accessible from the host used to access the LUN copy.
- If you plan to access LUN copies directly from the SnapVault secondary volume, you must create your igroups on the SnapVault SVM in advance.

You can access a LUN directly from the SnapVault secondary volume without having to first restore or clone the volume containing the LUN.

About this task

If a new Snapshot copy is added to the SnapVault secondary volume while you have a LUN mapped from a previous Snapshot copy, the contents of the mapped LUN changes. The LUN is still mapped with the same identifiers, but the data is taken from the new Snapshot copy. If the LUN size changes, some hosts automatically detect the size change; Windows hosts require a disk rescan to pick up any size change.

Steps

1. Run the `lun show` command to list the available LUNs in the SnapVault secondary volume.

In this example, you can see both the original LUNs in the primary volume `srcvolA` and the copies in the SnapVault secondary volume `dstvolB`:

```
cluster::> lun show
```

Vserver	Path	State	Mapped	Type	Size
vserverA	/vol/srcvolA/lun_A	online	mapped	windows	300.0GB
vserverA	/vol/srcvolA/lun_B	online	mapped	windows	300.0GB
vserverA	/vol/srcvolA/lun_C	online	mapped	windows	300.0GB
vserverB	/vol/dstvolB/lun_A	online	unmapped	windows	300.0GB
vserverB	/vol/dstvolB/lun_B	online	unmapped	windows	300.0GB
vserverB	/vol/dstvolB/lun_C	online	unmapped	windows	300.0GB

```
6 entries were displayed.
```

2. If the igroup for the desired host does not already exist on the SVM containing the SnapVault secondary volume, run the `igroup create` command to create an igroup.

This command creates an igroup for a Windows host that uses the iSCSI protocol:

```
cluster::> igrup create -vserver vserverB -igroup temp_igroup  
-protocol iscsi -ostype windows  
-initiator iqn.1991-05.com.microsoft:hostA
```

3. Run the `lun mapping create` command to map the desired LUN copy to the igroup.

```
cluster::> lun mapping create -vserver vserverB -path  
/vol/dstvolB/lun_A  
-igroup temp_igroup
```

4. Connect the host to the LUN and access the contents of the LUN as desired.

= Restore a single LUN from a SnapVault backup

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can restore a single LUN to a new location or to the original location. You can restore from any Snapshot copy in the SnapVault secondary volume. To restore the LUN to the original location, you first restore it to a new location and then copy it.

What you'll need

- The SnapVault relationship must be initialized and the SnapVault secondary volume must contain an appropriate Snapshot copy to restore.
- The storage virtual machine (SVM) containing the SnapVault secondary volume must have one or more LIFs with the desired SAN protocol that are accessible from the host used to access the LUN copy.
- The igroups must already exist on the SnapVault SVM.

About this task

The process includes creating a read-write volume clone from a Snapshot copy in the SnapVault secondary volume. You can use the LUN directly from the clone, or you can optionally copy the LUN contents back to the original LUN location.

The LUN in the clone has a different path and serial number from the original LUN. Persistent reservations are not retained.

Steps

1. Run the `snapmirror show` command to verify the secondary volume that contains the SnapVault backup.

```
cluster::> snapmirror show

Source          Dest      Mirror   Relation  Total           Last
Path           Type     Path      State    Status  Progress  Healthy Updated
-----  -----  -----  -----  -----  -----  -----  -----
vserverA:srcvolA
                  XDP  vserverB:dstvolB
                               Snapmirrored
                               Idle      -        true     -

```

2. Run the `volume snapshot show` command to identify the Snapshot copy that you want to restore the LUN from.

```
cluster::> volume snapshot show

Vserver  Volume  Snapshot          State  Size  Total%  Used%
-----  -----  -----  -----  -----  -----  -----  -----
vserverB
          dstvolB
          snap2.2013-02-10_0010  valid  124KB    0%    0%
          snap1.2013-02-10_0015  valid  112KB    0%    0%
          snap2.2013-02-11_0010  valid  164KB    0%    0%
```

3. Run the `volume clone create` command to create a read-write clone from the desired Snapshot copy.

The volume clone is created in the same aggregate as the SnapVault backup. There must be enough space in the aggregate to store the clone.

```
cluster::> volume clone create -vserver vserverB  
-flexclone dstvolB_clone -type RW -parent-volume dstvolB  
-parent-snapshot daily.2013-02-10_0010  
[Job 108] Job succeeded: Successful
```

4. Run the lun show command to list the LUNs in the volume clone.

```
cluster::> lun show -vserver vserverB -volume dstvolB_clone  
  
Vserver      Path          State   Mapped   Type  
-----  
vserverB    /vol/dstvolB_clone/lun_A  online  unmapped windows  
vserverB    /vol/dstvolB_clone/lun_B  online  unmapped windows  
vserverB    /vol/dstvolB_clone/lun_C  online  unmapped windows  
  
3 entries were displayed.
```

5. If the igroup for the desired host does not already exist on the SVM containing the SnapVault backup, run the igrup create command to create an igroup.

This example creates an igroup for a Windows host that uses the iSCSI protocol:

```
cluster::> igrup create -vserver vserverB -igroup temp_igroup  
-protocol iscsi -ostype windows  
-initiator iqn.1991-05.com.microsoft:hostA
```

6. Run the lun mapping create command to map the desired LUN copy to the igroup.

```
cluster::> lun mapping create -vserver vserverB  
-path /vol/dstvolB_clone/lun_C -igroup temp_igroup
```

7. Connect the host to the LUN and access the contents of the LUN, as desired.

The LUN is read-write and can be used in place of the original LUN. Because the LUN serial number is different, the host interprets it as a different LUN from the original.

8. Use a copy program on the host to copy the LUN contents back to the original LUN.

= Restore all LUNs in a volume from a SnapVault backup
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If one or more LUNs in a volume need to be restored from a SnapVault backup, you

can restore the entire volume. Restoring the volume affects all LUNs in the volume.

What you'll need

The SnapVault relationship must be initialized and the SnapVault secondary volume must contain an appropriate Snapshot copy to restore.

About this task

Restoring an entire volume returns the volume to the state it was in when the Snapshot copy was made. If a LUN was added to the volume after the Snapshot copy, that LUN is removed during the restore process.

After restoring the volume, the LUNs remain mapped to the igroups they were mapped to just before the restore. The LUN mapping might be different from the mapping at the time of the Snapshot copy. Persistent reservations on the LUNs from host clusters are retained.

Steps

1. Stop I/O to all LUNs in the volume.
2. Run the `snapmirror show` command to verify the secondary volume that contains the SnapVault secondary volume.

```
cluster::> snapmirror show

Source          Dest          Mirror  Relation  Total          Last
Path           Type   Path      State    Status  Progress  Healthy Updated
-----  -----
vserverA:srcvolA
          XDP  vserverB:dstvolB
                           Snapmirrored
                           Idle      -        true      -

```

3. Run the `volume snapshot show` command to identify the Snapshot copy that you want to restore from.

```
cluster::> volume snapshot show

Vserver  Volume  Snapshot          State  Size  Total%  Used%
-----  -----
vserverB
          dstvolB
          snap2.2013-02-10_0010  valid  124KB    0%    0%
          snap1.2013-02-10_0015  valid  112KB    0%    0%
          snap2.2013-02-11_0010  valid  164KB    0%    0%
```

4. Run the `snapmirror restore` command and specify the `-source-snapshot` option to specify the Snapshot copy to use.

The destination you specify for the restore is the original volume you are restoring to.

```
cluster::> snapmirror restore -destination-path vserverA:srcvolA  
-source-path vserverB:dstvolB -source-snapshot daily.2013-02-  
10_0010
```

Warning: All data newer than Snapshot copy hourly.2013-02-11_1205 on
volume vserverA:src_volA will be deleted.

Do you want to continue? {y|n}: y
[Job 98] Job is queued: snapmirror restore from source
"vserverB:dstvolB" for the snapshot daily.2013-02-10_0010.

5. If you are sharing LUNs across a host cluster, restore the persistent reservations on the LUNs from the affected hosts.

== Restoring a volume from a SnapVault backup

In the following example, the LUN named lun_D was added to the volume after the Snapshot copy was created. After restoring the entire volume from the Snapshot copy, lun_D no longer appears.

In the lun show command output, you can see the LUNs in the primary volume srcvolA and the read-only copies of those LUNs in the SnapVault secondary volume dstvolB. There is no copy of lun_D in the SnapVault backup.

```

cluster::> lun show
Vserver    Path          State   Mapped   Type      Size
-----  -----
vserverA  /vol/srcvolA/lun_A  online  mapped   windows  300.0GB
vserverA  /vol/srcvolA/lun_B  online  mapped   windows  300.0GB
vserverA  /vol/srcvolA/lun_C  online  mapped   windows  300.0GB
vserverA  /vol/srcvolA/lun_D  online  mapped   windows  250.0GB
vserverB  /vol/dstvolB/lun_A  online  unmapped windows  300.0GB
vserverB  /vol/dstvolB/lun_B  online  unmapped windows  300.0GB
vserverB  /vol/dstvolB/lun_C  online  unmapped windows  300.0GB

```

7 entries were displayed.

```

cluster::> snapmirror restore -destination-path vserverA:srcvolA
           -source-path vserverB:dstvolB
           -source-snapshot daily.2013-02-10_0010

```

Warning: All data newer than Snapshot copy hourly.2013-02-11_1205
on volume vserverA:src_volA will be deleted.

Do you want to continue? {y|n}: y
[Job 98] Job is queued: snapmirror restore from source
"vserverB:dstvolB" for the snapshot daily.2013-02-10_0010.

```

cluster::> lun show
Vserver    Path          State   Mapped   Type      Size
-----  -----
vserverA  /vol/srcvolA/lun_A  online  mapped   windows  300.0GB
vserverA  /vol/srcvolA/lun_B  online  mapped   windows  300.0GB
vserverA  /vol/srcvolA/lun_C  online  mapped   windows  300.0GB
vserverB  /vol/dstvolB/lun_A  online  unmapped windows  300.0GB
vserverB  /vol/dstvolB/lun_B  online  unmapped windows  300.0GB
vserverB  /vol/dstvolB/lun_C  online  unmapped windows  300.0GB

```

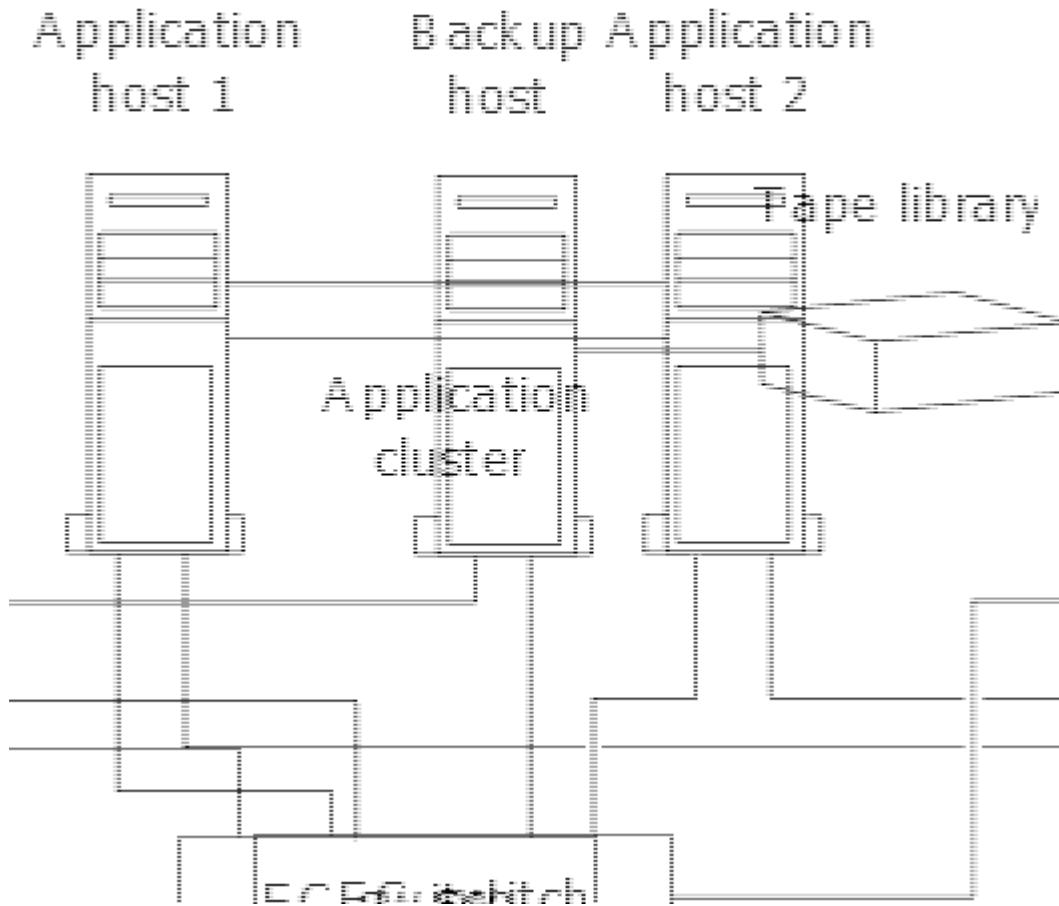

6 entries were displayed.

After the volume is restored from the SnapVault secondary volume, the source volume no longer contains lun_D. You do not need to remap the LUNs in the source volume after the restore because they are still mapped.

= How you can connect a host backup system to the primary storage system
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can back up SAN systems to tape through a separate backup host to avoid performance degradation on the application host.

It is imperative that you keep SAN and NAS data separated for backup purposes. The figure below shows the recommended physical configuration for a host backup system to the primary storage system. You must configure volumes as SAN-only. LUNs can be confined to a single volume or the LUNs can be spread across multiple volumes or storage systems.

Volumes on a host can consist of a single LUN mapped from the storage system or multiple LUNs using a volume manager, such as VxVM on HP-UX systems.

= Back up a LUN through a host backup system

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can use a cloned LUN from a Snapshot copy as source data for the host backup system.

What you'll need

A production LUN must exist and be mapped to an igroup that includes the WWPN or initiator node name of the application server. The LUN must also be formatted and accessible to the host

Steps

1. Save the contents of the host file system buffers to disk.

You can use the command provided by your host operating system, or you can use SnapDrive for Windows or SnapDrive for UNIX. You can also opt to make this step part of your SAN backup pre-processing script.

2. Use the volume snapshot create command to create a Snapshot copy of the production LUN.

```
volume snapshot create -vserver vs0 -volume vol3 -snapshot vol3_snapshot  
-comment "Single snapshot" -foreground false
```

3. Use the volume file clone create command to create a clone of the production LUN.

```
volume file clone create -vserver vs3 -volume vol3 -source-path lun1  
-snapshot-name snap_vol3 -destination-path lun1_backup
```

4. Use the lun igrup create command to create an igrup that includes the WWPN of the backup server.

```
lun igrup create -vserver vs3 -igroup igrup3 -protocol fc -ostype windows  
-initiator 10:00:00:00:c9:73:5b:91
```

5. Use the lun mapping create command to map the LUN clone you created in Step 3 to the backup host.

```
lun mapping create -vserver vs3 -volume vol3 -lun lun1_backup -igroup  
igroup3
```

You can opt to make this step part of your SAN backup application's post-processing script.

6. From the host, discover the new LUN and make the file system available to the host.

You can opt to make this step part of your SAN backup application's post-processing script.

7. Back up the data in the LUN clone from the backup host to tape by using your SAN backup application.

8. Use the lun modify command to take the LUN clone offline.

```
lun modify -vserver vs3 -path /vol/vol3/lun1_backup -state offline
```

9. Use the lun delete to remove the LUN clone.

```
lun delete -vserver vs3 -volume vol3 -lun lun1_backup
```

10. Use the volume snapshot delete command to remove the Snapshot copy.

```
volume snapshot delete -vserver vs3 -volume vol3 -snapshot vol3_snapshot
```

= Considerations for SAN configurations in a MetroCluster environment

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You must be aware of certain considerations when using SAN configurations in a MetroCluster environment.

- Two-node, four-node, and eight-node MetroCluster configurations do not support front-end FC fabric "routed" vSAN configurations.

- Two-node, four-node, and eight-node MetroCluster configurations support SAN protocols.
- When using SAN client configurations, you must check whether any special considerations for MetroCluster configurations are included in the notes that are provided in the Interoperability Matrix Tool (IMT).
- The MetroCluster is using the same WWPNs on both sides of the front-end SAN.

To avoid overlap when the old port goes offline and the new port comes online, use the following steps to configure the front-end switches:

For a...	Use these steps:
Cisco switch	<p>1. Connect to the switch and log in.</p> <p>2. Enter configuration mode:</p> <pre data-bbox="540 650 829 720">switch# config t switch(config) #</pre> <p>3. Overwrite the first device entry in the name server database with the new device:</p> <pre data-bbox="540 920 1432 990">switch(config)# no fcns reject-duplicate-pwwn vsan 1</pre> <p>4. In switches that are running NX-OS 8.x, confirm that the flogi quiesce timeout is set to zero:</p> <p>a. Display the quiesce timerval:</p> <pre data-bbox="564 1220 1442 1269">switch(config)# show flogi interval info i quiesce</pre> <pre data-bbox="605 1311 1263 1343">Stats: fs flogi quiesce timerval: 0</pre> <p>b. If the output in the previous step does not indicate that the timerval is zero, then set it to zero:</p> <pre data-bbox="564 1522 1139 1550">switch(config)# flogi scale enable</pre> <pre data-bbox="564 1592 1224 1619">switch(config)\$ flogi quiesce timeout 0</pre>

Brocade switch

1. Connect to the switch and log in.
2. Enter the `switchDisable` command.
3. Enter the `configure` command, and press **y** at the prompt.

```
F-Port login parameters (yes, y, no, n): [no] y
```

4. Choose setting 1:

```
- 0: First login take precedence over the second  
login (default)  
- 1: Second login overrides first login.  
- 2: the port type determines the behavior  
Enforce FLOGI/FDISC login: (0..2) [0] 1
```

5. Respond to the remaining prompts, or press **Ctrl + D**.
6. Enter the `switchEnable` command.

For further MetroCluster-specific host information, refer to the following NetApp Knowledgebase articles:

= SAN Concepts

= About SAN host provisioning

= SAN provisioning with iSCSI

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

In SAN environments, storage systems are targets that have storage target devices. For iSCSI and FC, the storage target devices are referred to as LUNs (logical units). For Non-Volatile Memory Express (NVMe) over Fibre Channel, the storage target devices are referred to as namespaces.

You configure storage by creating LUNs for iSCSI and FC or by creating namespaces for NVMe. The LUNs or namespaces are then accessed by hosts using Internet Small Computer Systems Interface (iSCSI) or Fibre Channel (FC) protocol networks.

To connect to iSCSI networks, hosts can use standard Ethernet network adapters (NICs), TCP offload engine (TOE) cards with software initiators, converged network adapters (CNAs), or dedicated iSCSI host

bus adapters (HBAs).

To connect to FC networks, hosts require FC HBAs or CNAs.

Supported FC protocols include:

- FC
- FCoE
- NVMe

== iSCSI target node network connections and names

iSCSI target nodes can connect to the network in several ways:

- Over Ethernet interfaces using software that is integrated into ONTAP.
- Over multiple system interfaces, with an interface used for iSCSI that can also transmit traffic for other protocols, such as SMB and NFS.
- Using a unified target adapter (UTA) or a converged network adapter (CNA).

Every iSCSI node must have a node name.

The two formats, or type designators, for iSCSI node names are *iqn* and *eui*. The SVM iSCSI target always uses the iqn-type designator. The initiator can use either the iqn-type or eui-type designator.

== Storage system node name

Each SVM running iSCSI has a default node name based on a reverse domain name and a unique encoding number.

The node name is displayed in the following format:

iqn.1992-08.com.netapp:sn.unique-encoding-number

The following example shows the default node name for a storage system with a unique encoding number:

iqn.1992-08.com.netapp:sn.812921059e6c11e097b3123478563412:vs.6

== TCP port for iSCSI

The iSCSI protocol is configured in ONTAP to use TCP port number 3260.

ONTAP does not support changing the port number for iSCSI. Port number 3260 is registered as part of the iSCSI specification and cannot be used by any other application or service.

Related information

[NetApp Documentation: ONTAP SAN Host Configuration](#)

= iSCSI service management

= iSCSI service management

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can manage the availability of the iSCSI service on the iSCSI logical interfaces of the storage virtual machine (SVM) by using the vserver iscsi interface enable or vserver iscsi interface disable commands.

By default, the iSCSI service is enabled on all iSCSI logical interfaces.

== How iSCSI is implemented on the host

iSCSI can be implemented on the host using hardware or software.

You can implement iSCSI in one of the following ways:

- Using Initiator software that uses the host's standard Ethernet interfaces.
- Through an iSCSI host bus adapter (HBA): An iSCSI HBA appears to the host operating system as a SCSI disk adapter with local disks.
- Using a TCP Offload Engine (TOE) adapter that offloads TCP/IP processing.

The iSCSI protocol processing is still performed by host software.

= How iSCSI authentication works

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

During the initial stage of an iSCSI session, the initiator sends a login request to the storage system to begin an iSCSI session. The storage system then either permits or denies the login request, or determine that a login is not required.

iSCSI authentication methods are:

- Challenge Handshake Authentication Protocol (CHAP)--The initiator logs in using a CHAP user name and password.

You can specify a CHAP password or generate a hexadecimal secret password. There are two types of CHAP user names and passwords:

- Inbound—The storage system authenticates the initiator.

Inbound settings are required if you are using CHAP authentication.

- Outbound—This is an optional setting to enable the initiator to authenticate the storage system.

You can use outbound settings only if you define an inbound user name and password on the storage system.

- deny—The initiator is denied access to the storage system.
- none—The storage system does not require authentication for the initiator.

You can define the list of initiators and their authentication methods. You can also define a default authentication method that applies to initiators that are not on this list.

Related information

= iSCSI initiator security management
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ONTAP provides a number of features for managing security for iSCSI initiators. You can define a list of iSCSI initiators and the authentication method for each, display the initiators and their associated authentication methods in the authentication list, add and remove initiators from the authentication list, and define the default iSCSI initiator authentication method for initiators not in the list.

= iSCSI endpoint isolation
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Beginning with ONTAP 9.1 existing iSCSI security commands were enhanced to accept an IP address range, or multiple IP addresses.

All iSCSI initiators must provide origination IP addresses when establishing a session or connection with a target. This new functionality prevents an initiator from logging into the cluster if the origination IP address is unsupported or unknown, providing a unique identification scheme. Any initiator originating from an unsupported or unknown IP address will have their login rejected at the iSCSI session layer, preventing the initiator from accessing any LUN or volume within the cluster.

Implement this new functionality with two new commands to help manage pre-existing entries.

== Add initiator address range

Improve iSCSI initiator security management by adding an IP address range, or multiple IP addresses with the vserver iscsi security add-initiator-address-range command.

```
cluster1::> vserver iscsi security add-initiator-address-range
```

== Remove initiator address range

Remove an IP address range, or multiple IP addresses, with the vserver iscsi security remove-initiator-address-range command.

```
cluster1::> vserver iscsi security remove-initiator-address-range
```

= What CHAP authentication is
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The Challenge Handshake Authentication Protocol (CHAP) enables authenticated communication between iSCSI initiators and targets. When you use CHAP authentication, you define CHAP user names and passwords on both the initiator and the storage system.

During the initial stage of an iSCSI session, the initiator sends a login request to the storage system to begin the session. The login request includes the initiator's CHAP user name and CHAP algorithm. The storage system responds with a CHAP challenge. The initiator provides a CHAP response. The storage system verifies the response and authenticates the initiator. The CHAP password is used to compute the response.

== Guidelines for using CHAP authentication

You should follow certain guidelines when using CHAP authentication.

- If you define an inbound user name and password on the storage system, you must use the same user name and password for outbound CHAP settings on the initiator. If you also define an outbound user name and password on the storage system to enable bidirectional authentication, you must use the same user name and password for inbound CHAP settings on the initiator.
- You cannot use the same user name and password for inbound and outbound settings on the storage system.
- CHAP user names can be 1 to 128 bytes.

A null user name is not allowed.

- CHAP passwords (secrets) can be 1 to 512 bytes.

Passwords can be hexadecimal values or strings. For hexadecimal values, you should enter the value with a prefix of "0x" or "0X". A null password is not allowed.

- For additional restrictions, you should see the initiator's documentation.

For example, the Microsoft iSCSI software initiator requires both the initiator and target CHAP passwords to be at least 12 bytes if IPsec encryption is not being used. The maximum password length is 16 bytes regardless of whether IPsec is used.

= How using iSCSI interface access lists to limit initiator interfaces can increase performance and security
:icons: font

:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

iSCSI interface access lists can be used to limit the number of LIFs in an SVM that an initiator can access, thereby increasing performance and security.

When an initiator begins a discovery session using an iSCSI `SendTargets` command, it receives the IP addresses associated with the LIF (network interface) that is in the access list. By default, all initiators have access to all iSCSI LIFs in the SVM. You can use the access list to restrict the number of LIFs in an SVM that an initiator has access to.

= iSNS server registration requirement

= What iSNS is
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The Internet Storage Name Service (iSNS) is a protocol that enables automated discovery and management of iSCSI devices on a TCP/IP storage network. An iSNS

server maintains information about active iSCSI devices on the network, including their IP addresses, iSCSI node names IQN's, and portal groups.

You can obtain an iSNS server from a third-party vendor. If you have an iSNS server on your network configured and enabled for use by the initiator and target, you can use the management LIF for a storage virtual machine (SVM) to register all the iSCSI LIFs for that SVM on the iSNS server. After the registration is complete, the iSCSI initiator can query the iSNS server to discover all the LIFs for that particular SVM.

If you decide to use an iSNS service, you must ensure that your storage virtual machines (SVMs) are properly registered with an Internet Storage Name Service (iSNS) server.

If you do not have an iSNS server on your network, you must manually configure each target to be visible to the host.

== What an iSNS server does

An iSNS server uses the Internet Storage Name Service (iSNS) protocol to maintain information about active iSCSI devices on the network, including their IP addresses, iSCSI node names (IQNs), and portal groups.

The iSNS protocol enables automated discovery and management of iSCSI devices on an IP storage network. An iSCSI initiator can query the iSNS server to discover iSCSI target devices.

NetApp does not supply or resell iSNS servers. You can obtain these servers from a vendor supported by NetApp.

= How SVMs interact with an iSNS server

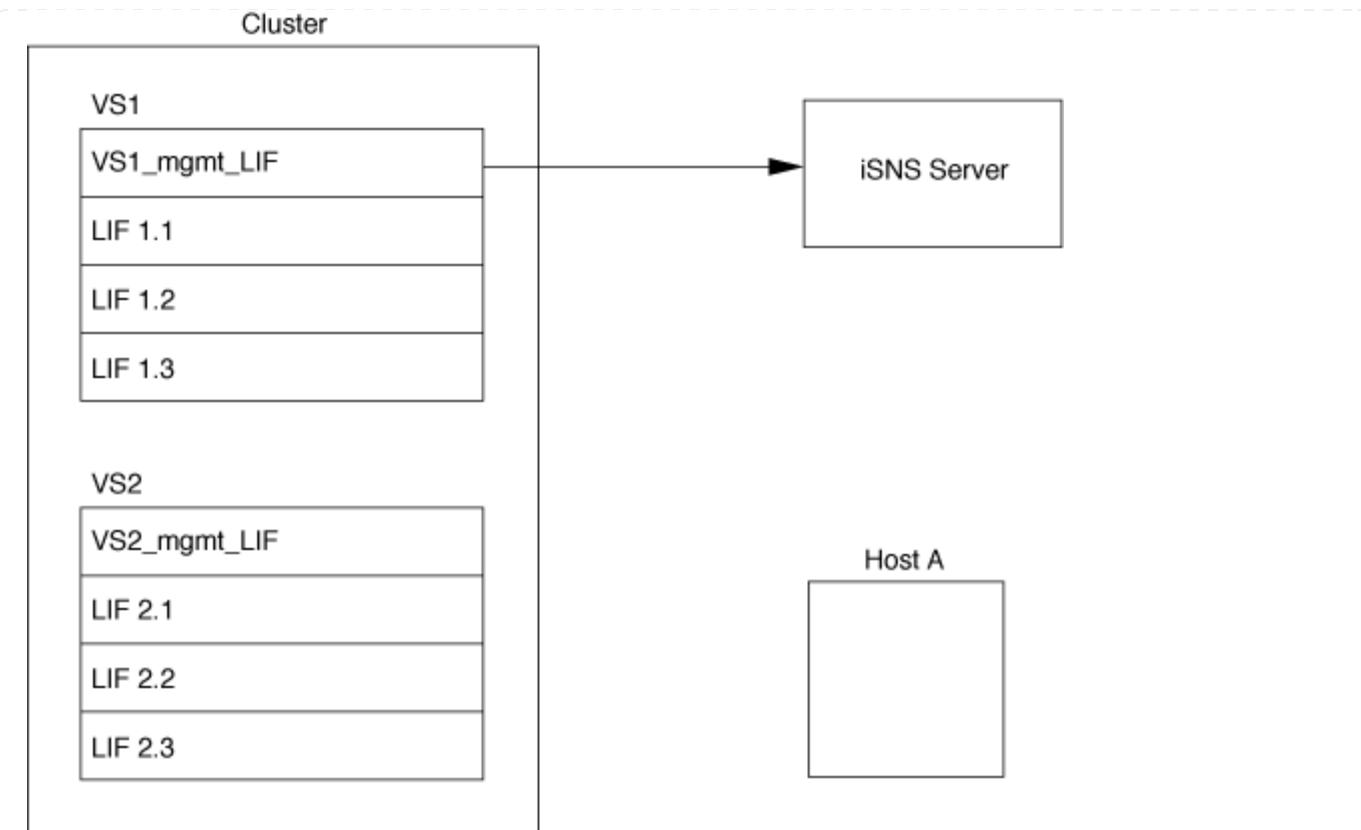

:icons: font

:relative_path: ./san-admin/

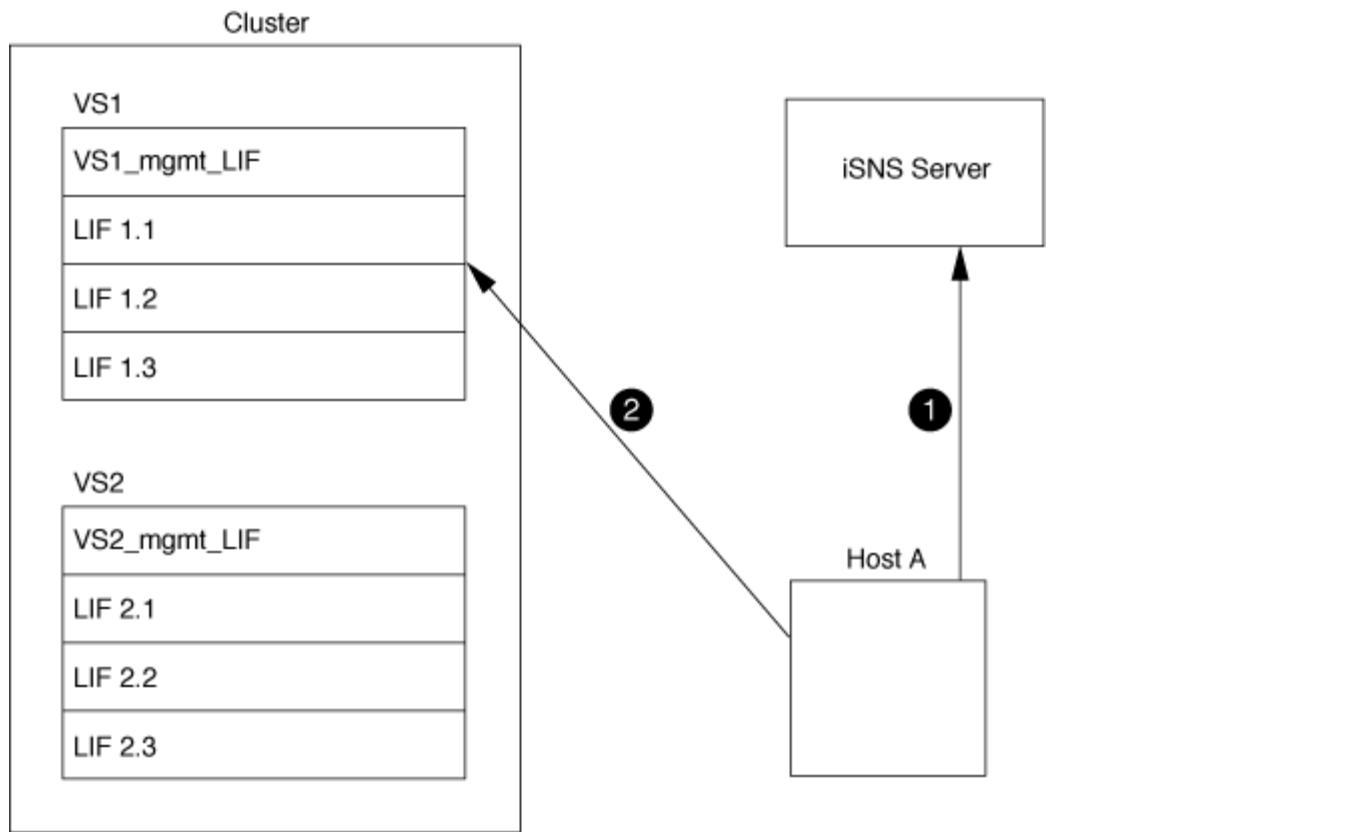

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

The iSNS server communicates with each storage virtual machine (SVM) through the SVM management LIF. The management LIF registers all iSCSI target node name, alias, and portal information with the iSNS service for a specific SVM.

In the following example, SVM VS1 uses the SVM management LIF vs1_mgmt_lif to register with the iSNS server. During iSNS registration, an SVM sends all the iSCSI LIFs through the SVM management LIF to the iSNS Server. After the iSNS registration is complete, the iSNS server has a list of all the LIFs serving iSCSI in VS1. If a cluster contains multiple SVMs, each SVM must register individually with the iSNS server to use the iSNS service.

In the next example, after the iSNS server completes the registration with the target, Host A can discover all the LIFs for VS1 through the iSNS server as indicated in step 1. After Host A completes the discovery of the LIFs for VS1, Host A can establish a connection with any of the LIFs in VS1 as shown in step 2. Host A is not aware of any of the LIFs in VS2 until the management LIF VS2_mgmt_LIF for VS2 registers with the iSNS server.

However, if you define the interface access lists, the host can only use the defined LIFs in the interface access list to access the target.

After iSNS is initially configured, ONTAP automatically updates the iSNS server when the SVM configuration settings change.

A delay of a few minutes can occur between the time you make the configuration changes and when ONTAP sends the update to the iSNS server. Force an immediate update of the iSNS information on the iSNS server: `vserver iscsi isns update`

= Commands for managing iSNS

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ONTAP provides commands to manage your iSNS service.

If you want to...	Use this command...
Configure an iSNS service	<code>vserver iscsi isns create</code>
Start an iSNS service	<code>vserver iscsi isns start</code>
Modify an iSNS service	<code>vserver iscsi isns modify</code>
Display iSNS service configuration	<code>vserver iscsi isns show</code>

If you want to...	Use this command...
Force an update of registered iSNS information	vserver iscsi isns update
Stop an iSNS service	vserver iscsi isns stop
Remove an iSNS service	vserver iscsi isns delete
View the man page for a command	man <i>command name</i>

See the man page for each command for more information.

= SAN provisioning with FC

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You should be aware of the important concepts that are required to understand how ONTAP implements an FC SAN.

== How FC target nodes connect to the network

Storage systems and hosts have adapters so that they can be connected to FC switches with cables.

When a node is connected to the FC SAN, each SVM registers the World Wide Port Name (WWPN) of its LIF with the switch Fabric Name Service. The WWNN of the SVM and the WWPN of each LIF is automatically assigned by ONTAP..

Direct-connection to nodes from hosts with FC is not supported, NPIV is required and this requires a switch to be used. With iSCSI sessions, communication works with connections that are either network routed or direct-connect. However, both of these methods are supported with ONTAP.

== How FC nodes are identified

Each SVM configured with FC is identified by a worldwide node name (WWNN).

== How WWPNs are used

WWPNs identify each LIF in an SVM configured to support FC. These LIFs utilize the physical FC ports in each node in the cluster, which can be FC target cards, UTA or UTA2 configured as FC or FCoE in the nodes.

- Creating an initiator group

The WWPNs of the host's HBAs are used to create an initiator group (igroup). An igroup is used to control host access to specific LUNs. You can create an igroup by specifying a collection of WWPNs of initiators in an FC network. When you map a LUN on a storage system to an igroup, you can grant all the initiators in that group access to that LUN. If a host's WWPN is not in an igroup that is mapped to a LUN, that host does not have access to the LUN. This means that the LUNs do not appear as disks on that host.

You can also create port sets to make a LUN visible only on specific target ports. A port set consists of a group of FC target ports. You can bind an igroup to a port set. Any host in the igroup can access the LUNs only by connecting to the target ports in the port set.

- Uniquely identifying FC LIFs

WWPNs uniquely identify each FC logical interface. The host operating system uses the combination of the WWNN and WWPN to identify SVMs and FC LIFs. Some operating systems require persistent binding to ensure that the LUN appears at the same target ID on the host.

== How worldwide name assignments work

Worldwide names are created sequentially in ONTAP. However, because of the way ONTAP assigns them, they might appear to be assigned in a non-sequential order.

Each adapter has a pre-configured WWPN and WWNN, but ONTAP does not use these pre-configured values. Instead, ONTAP assigns its own WWPNs or WWNNs, based on the MAC addresses of the onboard Ethernet ports.

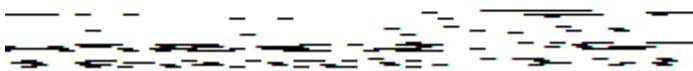

The worldwide names might appear to be non-sequential when assigned for the following reasons:

- Worldwide names are assigned across all the nodes and storage virtual machines (SVMs) in the cluster.
- Freed worldwide names are recycled and added back to the pool of available names.

== How FC switches are identified

Fibre Channel switches have one worldwide node name (WWNN) for the device itself, and one worldwide port name (WWPN) for each of its ports.

For example, the following diagram shows how the WWPNs are assigned to each of the ports on a 16-port Brocade switch. For details about how the ports are numbered for a particular switch, see the vendor-supplied documentation for that switch.

Port 0, WWPN 20:00:00:60:69:51:06:b4

Port 1, WWPN 20:01:00:60:69:51:06:b4

Port 14, WWPN 20:0e:00:60:69:51:06:b4

Port 15, WWPN 20:0f:00:60:69:51:06:b4

= SAN provisioning with NVMe

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

Beginning with ONTAP 9.4, NVMe/FC is supported in SAN environment. NVMe/FC enables storage administrators to provision namespaces and subsystems and then map the namespaces to subsystems, similar to the way LUNs are provisioned and mapped to igroups for FC and iSCSI.

An NVMe namespace is a quantity of non-volatile memory that can be formatted into logical blocks. Namespaces are the equivalent of LUNs for FC and iSCSI protocols, and an NVMe subsystem is analogous to an igroup. An NVMe subsystem can be associated with initiators so that namespaces within the subsystem can be accessed by the associated initiators.

Although analogous in function, NVMe namespaces do not support all features supported by LUNs.

Beginning with ONTAP 9.5 a license is required to support host-facing data access with NVMe. If NVMe is enabled in ONTAP 9.4, a 90 day grace period is given to acquire the license after upgrading to ONTAP 9.5. You can enable the license using the following command:

```
system license add -license-code NVMe_license_key
```

Related information

[NetApp Technical Report 4684: Implementing and Configuring Modern SANs with NVMe/FC](#)

= About SAN volumes

= About SAN volumes overview

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ONTAP provides three basic volume provisioning options: thick provisioning, thin provisioning, and semi-thick provisioning. Each option uses different ways to manage the volume space and the space requirements for ONTAP block sharing technologies. Understanding how the options work enables you to choose the best option for your environment.

Putting SAN LUNs and NAS shares in the same FlexVol volume is not recommended. You should provision separate FlexVol volumes specifically for your SAN LUNs and you should provision separate FlexVol volumes specifically to your NAS shares. This simplifies management and replication deployments and parallels the way FlexVol volumes are supported in Active IQ Unified Manager (formerly OnCommand Unified Manager).

-- Thin provisioning for volumes

When a thinly provisioned volume is created, ONTAP does not reserve any extra space when the volume is created. As data is written to the volume, the volume requests the storage it needs from the aggregate to accommodate the write operation. Using thin-provisioned volumes enables you to overcommit your aggregate, which introduces the possibility of the volume not being able to secure the space it needs when the aggregate runs out of free space.

You create a thin-provisioned FlexVol volume by setting its `-space-guarantee` option to `none`.

== Thick provisioning for volumes

When a thick-provisioned volume is created, ONTAP sets aside enough storage from the aggregate to ensure that any block in the volume can be written to at any time. When you configure a volume to use thick provisioning, you can employ any of the ONTAP storage efficiency capabilities, such as compression and deduplication, to offset the larger upfront storage requirements.

You create a thick-provisioned FlexVol volume by setting its `-space-slo` (service level objective) option to `thick`.

== Semi-thick provisioning for volumes

When a volume using semi-thick provisioning is created, ONTAP sets aside storage space from the aggregate to account for the volume size. If the volume is running out of free space because blocks are in use by block-sharing technologies, ONTAP makes an effort to delete protection data objects (Snapshot copies and FlexClone files and LUNs) to free up the space they are holding. As long as ONTAP can delete the protection data objects fast enough to keep pace with the space required for overwrites, the write operations continue to succeed. This is called a “best effort” write guarantee.

You cannot employ storage efficiency technologies such as deduplication, compression, and compaction on a volume that is using semi-thick provisioning.

You create a semi-thick-provisioned FlexVol volume by setting its `-space-slo` (service level objective) option to `semi-thick`.

== Use with space-reserved files and LUNs

A space-reserved file or LUN is one for which storage is allocated when it is created. Historically, NetApp has used the term “thin-provisioned LUN” to mean a LUN for which space reservation is disabled (a non-space-reserved LUN).

Non-space-reserved files are not generally referred to as “thin-provisioned files”.

The following table summarizes the major differences in how the three volume provisioning options can be used with space-reserved files and LUNs:

Volume provisioning	LUN/file space reservation	Overwrites	Protection data ²	Storage efficiency ³
Thick	Supported	Guaranteed ¹	Guaranteed	Supported
Thin	No effect	None	Guaranteed	Supported
Semi-thick	Supported	Best effort ¹	Best effort	Not supported

Notes

1. The ability to guarantee overwrites or provide a best-effort overwrite assurance requires that space reservation is enabled on the LUN or file.
2. Protection data includes Snapshot copies, and FlexClone files and LUNs marked for automatic deletion (backup clones).

3. Storage efficiency includes deduplication, compression, any FlexClone files and LUNs not marked for automatic deletion (active clones), and FlexClone subfiles (used for Copy Offload).

== Support for SCSI thin-provisioned LUNs

ONTAP supports T10 SCSI thin-provisioned LUNs as well as NetApp thin-provisioned LUNs. T10 SCSI thin provisioning enables host applications to support SCSI features including LUN space reclamation and LUN space monitoring capabilities for blocks environments. T10 SCSI thin provisioning must be supported by your SCSI host software.

You use the ONTAP space-allocation setting to enable/disable support for the T10 thin provisioning on a LUN. You use the ONTAP space-allocation enable setting to enable T10 SCSI thin provisioning on a LUN.

The [-space-allocation {enabled|disabled}] command in the ONTAP Command Reference Manual has more information to enable/disable support for the T10 thin provisioning and to enable T10 SCSI thin provisioning on a LUN.

ONTAP 9 commands

= Configure volume provisioning options
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can configure a volume for thin provisioning, thick provisioning, or semi-thick provisioning.

About this task

Setting the -space-slo option to thick ensures the following:

- The entire volume is preallocated in the aggregate. You cannot use the volume create or volume modify command to configure the volume's -space-guarantee option.
- 100% of the space required for overwrites is reserved. You cannot use the volume modify command to configure the volume's -fractional-reserve option

Setting the -space-slo option to semi-thick ensures the following:

- The entire volume is preallocated in the aggregate. You cannot use the volume create or volume modify command to configure the volume's -space-guarantee option.
- No space is reserved for overwrites. You can use the volume modify command to configure the volume's -fractional-reserve option.
- Automatic deletion of Snapshot copies is enabled.

Step

1. Configure volume provisioning options:

```
volume create -vserver vserver_name -volume volume_name -aggregate
aggregate_name -space-slo none|thick|semi-thick -space-guarantee
none|volume
```

The `-space-guarantee` option defaults to `none` for AFF systems and for non-AFF DP volumes. Otherwise, it defaults to `volume`. For existing FlexVol volumes, use the `volume modify` command to configure provisioning options.

The following command configures `vol1` on SVM `vs1` for thin provisioning:

```
cluster1::> volume create -vserver vs1 -volume vol1 -space-guarantee none
```

The following command configures `vol1` on SVM `vs1` for thick provisioning:

```
cluster1::> volume create -vserver vs1 -volume vol1 -space-slo thick
```

The following command configures `vol1` on SVM `vs1` for semi-thick provisioning:

```
cluster1::> volume create -vserver vs1 -volume vol1 -space-slo semi-thick
```

= SAN volume configuration options

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You must set various options on the volume containing your LUN. The way you set the volume options determines the amount of space available to LUNs in the volume.

== Autogrow

You can enable or disable Autogrow. If you enable it, autogrow allows ONTAP to automatically increase the size of the volume up to a maximum size that you predetermine. There must be space available in the containing aggregate to support the automatic growth of the volume. Therefore, if you enable autogrow, you must monitor the free space in the containing aggregate and add more when needed.

Autogrow cannot be triggered to support Snapshot creation. If you attempt to create a Snapshot copy and there is insufficient space on the volume, the Snapshot creation fails, even with autogrow enabled.

If autogrow is disabled, the size of your volume will remain the same.

== Autoshrink

You can enable or disable Autoshrink. If you enable it, autoshrink allows ONTAP to automatically decrease the overall size of a volume when the amount of space consumed in the volume decreases a predetermined threshold. This increases storage efficiency by triggering volumes to automatically release unused free space.

== Snapshot autodelete

Snapshot autodelete automatically deletes Snapshot copies when one of the following occurs:

- The volume is nearly full.
- The Snapshot reserve space is nearly full.
- The overwrite reserve space is full.

You can configure Snapshot autodelete to delete Snapshot copies from oldest to newest or from newest to oldest. Snapshot autodelete does not delete Snapshot copies that are linked to Snapshot copies in cloned volumes or LUNs.

If your volume needs additional space and you have enabled both autogrow and Snapshot autodelete, by default, ONTAP attempts to acquire the needed space by triggering autogrow first. If enough space is not acquired through autogrow, then Snapshot autodelete is triggered.

== Snapshot reserve

Snapshot reserve defines the amount of space in the volume reserved for Snapshot copies. Space allocated to Snapshot reserve cannot be used for any other purpose. If all of the space allocated for Snapshot reserve is used, then Snapshot copies begin to consume additional space on the volume.

= Requirement for moving volumes in SAN environments

:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Before you move a volume that contains LUNs or namespaces, you must meet certain requirements.

- For volumes containing one or more LUNs, you should have a minimum of two paths per LUN (LIFs) connecting to each node in the cluster.

This eliminates single points of failure and enables the system to survive component failures.

- For volumes containing namespaces, the cluster must be running ONTAP 9.6 or later.

Volume move is not supported for NVMe configurations running ONTAP 9.5.

= Considerations for setting fractional reserve

:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Fractional reserve, also called *LUN overwrite reserve*, enables you to turn off overwrite reserve for space-reserved LUNs and files in a FlexVol volume. This can help you maximize your storage utilization, but if your environment is negatively affected by write operations failing due to lack of space, you must understand the requirements that this configuration imposes.

The fractional reserve setting is expressed as a percentage; the only valid values are 0 and 100 percent. The fractional reserve setting is an attribute of the volume.

Setting fractional reserve to 0 increases your storage utilization. However, an application accessing data residing in the volume could experience a data outage if the volume is out of free space, even with the volume guarantee set to volume. With proper volume configuration and use, however, you can minimize

the chance of writes failing. ONTAP provides a “best effort” write guarantee for volumes with fractional reserve set to 0 when *all* of the following requirements are met:

- Deduplication is not in use
- Compression is not in use
- FlexClone sub-files are not in use
- All FlexClone files and FlexClone LUNs are enabled for automatic deletion

This is not the default setting. You must explicitly enable automatic deletion, either at creation time or by modifying the FlexClone file or FlexClone LUN after it is created.

- ODX and FlexClone copy offload are not in use
- Volume guarantee is set to `volume`
- File or LUN space reservation is enabled
- Volume Snapshot reserve is set to 0
- Volume Snapshot copy automatic deletion is enabled with a commitment level of `destroy`, a `destroy` list of `lun_clone`, `vol_clone`, `cifs_share`, `file_clone`, `sfsr`, and a trigger of `volume`

This setting also ensures that FlexClone files and FlexClone LUNs are deleted when necessary.

Note that if your rate of change is high, in rare cases the Snapshot copy automatic deletion could fall behind, resulting in the volume running out of space, even with all of the above required configuration settings in use.

In addition, you can optionally use the volume autogrow capability to decrease the likelihood of volume Snapshot copies needing to be deleted automatically. If you enable the autogrow capability, you must monitor the free space in the associated aggregate. If the aggregate becomes full enough that the volume is prevented from growing, more Snapshot copies will probably be deleted as the free space in the volume is depleted.

If you cannot meet all of the above configuration requirements and you need to ensure that the volume does not run out of space, you must set the volume’s fractional reserve setting to 100. This requires more free space up front, but guarantees that data modification operations will succeed even when the technologies listed above are in use.

The default value and allowed values for the fractional reserve setting depend on the guarantee of the volume:

Volume guarantee	Default fractional reserve	Allowed values
Volume	100	0, 100
None	0	0, 100

= About host-side space management

= Host-side space management overview

:icons: font

:relative_path: ./san-admin/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/ ./smb-admin/..media/
```

In a thinly provisioned environment, host side space management completes the process of managing space from the storage system that has been freed in the host file system.

A host file system contains metadata to keep track of which blocks are available to store new data and which blocks contain valid data that must not be overwritten. This metadata is stored within the LUN. When a file is deleted in the host file system, the file system metadata is updated to mark that file's blocks as free space. Total file system free space is then recalculated to include the newly freed blocks. To the storage system, these metadata updates appear no different from any other writes being performed by the host. Therefore, the storage system is unaware that any deletions have occurred.

This creates a discrepancy between the amount of free space reported by the host and the amount of free space reported by the underlying storage system. For example, suppose you have a newly provisioned 200-GB LUN assigned to your host by your storage system. Both the host and the storage system report 200 GB of free space. Your host then writes 100 GB of data. At this point, both the host and storage system report 100 GB of used space and 100 GB of unused space.

Then you delete 50 GB of data from your host. At this point, your host will report 50 GB of used space and 150 GB of unused space. However, your storage system will report 100 GB of used space and 100 GB of unused space.

Host-side space management uses various methods to reconcile the space differential between the host and the storage system.

= Automatic host-side space management with SCSI thinly provisioned LUNs

:icons: font

:relative_path: ./san-admin/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/ ./smb-admin/..media/
```

If your host supports SCSI thin provisioning, you can enable the space-allocation option in ONTAP to turn on automatic host-side space management.

Enabling SCSI thin provisioning enables you to do the following.

- Automatic host-side space management

When data is deleted on a host that supports SCSI thin provisioning, host-side space management identifies the blocks of deleted data on the host file system and automatically issues one or more SCSI UNMAP commands to free corresponding blocks on the storage system.

- Notify the host when a LUN runs out of space while keeping the LUN online

On hosts that do not support SCSI thin provisioning, when the volume containing LUN runs out of space and cannot automatically grow, ONTAP takes the LUN offline. However, on hosts that support SCSI thin provisioning, ONTAP does not take the LUN offline when it runs out of space. The LUN remains online in read-only mode and the host is notified that the LUN can no longer accept writes.

Related information

[ONTAP SAN host configuration](#)

= Enable space allocation for SCSI thinly provisioned LUNs

```
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

If you set the `space-allocation` option to `enabled`, ONTAP notifies the host when the volume has run out of space and the LUN in the volume cannot accept writes. This option also enables ONTAP to reclaim space automatically when your host deletes data.

About this task

The `space-allocation` option is set to `disabled` by default, and you must take the LUN offline to enable space allocation. After you enable space allocation, you must perform discovery on the host before the host will recognize that space allocation has been enabled.

Steps

1. Set the `-space-allocation` parameter to `enabled`:

```
lun modify -vserver vserver_name -volume volume_name -lun lun_name -space
-allocation enabled
```

2. Verify that space allocation is enabled:

```
lun show -vserver vserver_name -volume volume_name -lun lun_name -fields
space-allocation
```

3. Bring the LUN online:

```
lun modify -vserver vserver_name -volume volume_name -lun lun_name -state
online
```

4. On the host, rescan all disks to ensure that the change to the `-space-allocation` option is correctly discovered.

= Host support for SCSI thin provisioning

```
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

To leverage the benefits of SCSI thin provisioning, it must be supported by your host. SCSI thin provisioning uses the Logical Block Provisioning feature as defined in the SCSI SBC-3 standard. Only hosts that support this standard can use SCSI thin provisioning in ONTAP.

The following hosts currently support SCSI thin provisioning when you enable space allocation:

- VMware ESX 5.0 and later
- Red Hat Enterprise Linux 6.2 and later
- Citrix XenServer 6.5 and later
- Microsoft Windows 2012
- Microsoft Windows 2016

When you enable the space allocation functionality in ONTAP, you turn on the following SCSI thin provisioning features:

- Unmapping and reporting space usage for space reclamation
- Reporting resource exhaustion errors

= Simplified host management with SnapCenter

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can use SnapCenter software to simplify some of the management and data protection tasks associated with iSCSI and FC storage. SnapCenter is an optional management package for Windows and UNIX hosts.

You can use SnapCenter Software to easily create virtual disks from pools of storage that can be distributed among several storage systems and to automate storage provisioning tasks and simplify the process of creating Snapshot copies and clones from Snapshot copies consistent with host data.

See NetApp product documentation for more information on SnapCenter.

= About igroups

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Initiator groups (igroups) are tables of FC protocol host WWPNs or iSCSI host node names. You can define igroups and map them to LUNs to control which initiators have access to LUNs.

Typically, you want all of the host's initiator ports or software initiators to have access to a LUN. If you are using multipathing software or have clustered hosts, each initiator port or software initiator of each clustered host needs redundant paths to the same LUN.

You can create igroups that specify which initiators have access to the LUNs either before or after you create LUNs, but you must create igroups before you can map a LUN to an igroup.

Initiator groups can have multiple initiators, and multiple igroups can have the same initiator. However, you cannot map a LUN to multiple igroups that have the same initiator. An initiator cannot be a member of igroups of differing ostypes.

= Example of how igroups give LUN access

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can create multiple igroups to define which LUNs are available to your hosts. For example, if you have a host cluster, you can use igroups to ensure that specific LUNs are visible to only one host in the cluster or to all of the hosts in the cluster.

The following table illustrates how four igroups give access to the LUNs for four different hosts that are accessing the storage system. The clustered hosts (Host3 and Host4) are both members of the same

igroup (group3) and can access the LUNs mapped to this igroup. The igroup named group4 contains the WWPNs of Host4 to store local information that is not intended to be seen by its partner.

Hosts with HBA WWPNs, IQNs, or EUIs	igroups	WWPNs, IQNs, EUIs added to igroups	LUNs mapped to igroups
Host1, single-path (iSCSI software initiator) iqn.1991- 05.com.microsoft:host1	group1	iqn.1991- 05.com.microsoft:host1	/vol/vol2/lun1
Host2, multipath (two HBAs) 10:00:00:00:c9:2b:6b:3c 10:00:00:00:c9:2b:02:3c	group2	10:00:00:00:c9:2b:6b:3c 10:00:00:00:c9:2b:02:3c	/vol/vol2/lun2
Host3, multipath, clustered with host 4 10:00:00:00:c9:2b:32:1b 10:00:00:00:c9:2b:41:02	group3	10:00:00:00:c9:2b:32:1b 10:00:00:00:c9:2b:41:02 10:00:00:00:c9:2b:51:2c 10:00:00:00:c9:2b:47:a2	/vol/vol2/qtree1/l un3
Host4, multipath, clustered (not visible to Host3) 10:00:00:00:c9:2b:51:2c 10:00:00:00:c9:2b:47:a2	group4	10:00:00:00:c9:2b:51:2c 10:00:00:00:c9:2b:47:a2	/vol/vol2/qtree2/l un4 /vol/vol2/qtree1/l un5

= Specify initiator WWPNs and iSCSI node names for an igroup

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You can specify the iSCSI node names and WWPNs of the initiators when you create an igroup or you can add them later. If you choose to specify the initiator iSCSI node names and WWPNs when you create the LUN, they can be removed later, if needed.

Follow the instructions in your Host Utilities documentation to obtain WWPNs and to find the iSCSI node names associated with a specific host. For hosts running ESX software, use Virtual Storage Console.

= Storage virtualization with VMware and Microsoft copy offload

= Storage virtualization with VMware and Microsoft copy offload overview

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

VMware and Microsoft support copy offload operations to increase performance and network throughput. You must configure your system to meet the requirements of the VMware and Windows operating system environments to use their respective copy offload functions.

When using VMware and Microsoft copy offload in virtualized environments, your LUNs must be aligned. Unaligned LUNs can degrade performance.

== Advantages of using a virtualized SAN environment

Creating a virtualized environment by using storage virtual machines (SVMs) and LIFs enables you to expand your SAN environment to all of the nodes in your cluster.

- Distributed management

You can log in to any node in the SVM to administer all of the nodes in a cluster.

- Increased data access

With MPIO and ALUA, you have access to your data through any active iSCSI or FC LIFs for the SVM.

- Controlled LUN access

If you use SLM and portsets, you can limit which LIFs an initiator can use to access LUNs.

= How LUN access works in a virtualized environment

:icons: font

:relative_path: ./san-admin/

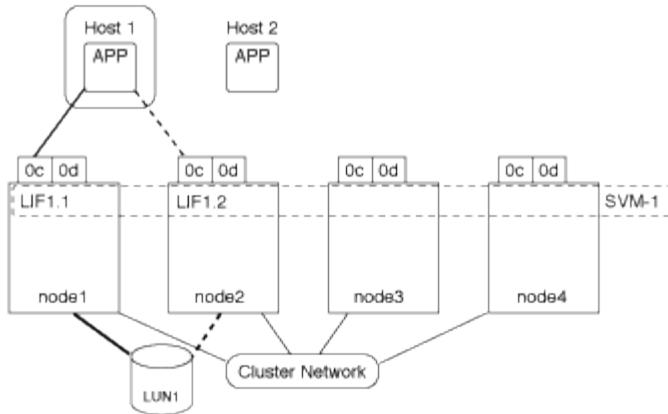

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

In a virtualized environment, LIFs enable hosts (clients) to access LUNs through optimized and unoptimized paths.

A LIF is a logical interface that connects the SVM to a physical port. Although multiple SVMs can have multiple LIFs on the same port, a LIF belongs to one SVM. You can access LUNs through the SVMs LIFs.

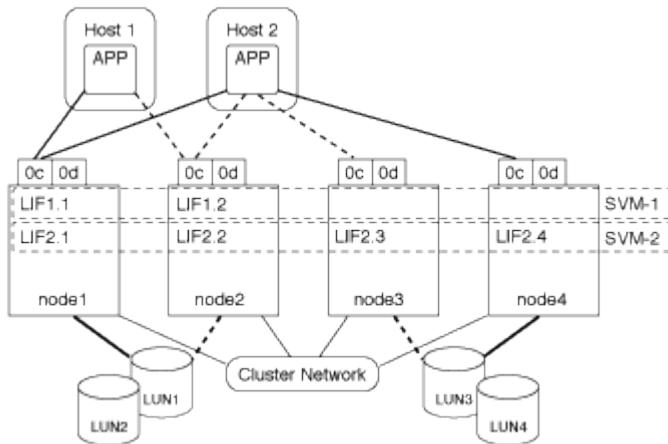

Example of LUN access with a single SVM in a cluster

In the following example, Host 1 connects to LIF1.1 and LIF1.2 in SVM-1 to access LUN1. LIF1.1 uses the physical port node1:0c and LIF1.2 uses the node2:0c. LIF1.1 and LIF1.2 belongs only to SVM-1. If a new LUN is created on node 1 or node 2, for SVM-1, then it can use these same LIFs. If a new SVM is created, then new LIFs can be created using physical ports 0c or 0d on both the nodes.

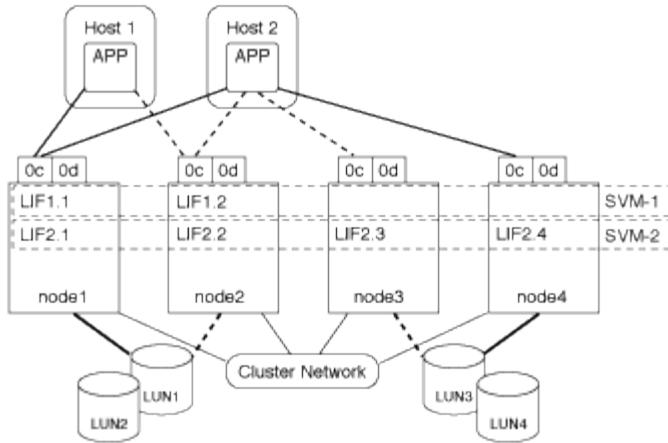

Example of LUN access with multiple SVMs in a cluster

A physical port can support multiple LIFs serving different SVMs. Because LIFs are associated with a particular SVM, the cluster nodes can send the incoming data traffic to the correct SVM. In the following example, each node from 1 through 4 has a LIF for SVM-2 using the physical port 0c on each node. Host 1 connects to LIF1.1 and LIF1.2 in SVM-1 to access LUN1. Host 2 connects to LIF2.1 and LIF2.2 in SVM-2 to access LUN2. Both SVMs are sharing the physical port 0c on the nodes 1 and 2. SVM-2 has additional LIFs that Host 2 is using to access LUNs 3 and 4. These LIFs are using physical port 0c on nodes 3 and 4. Multiple SVMs can share the physical ports on the nodes.

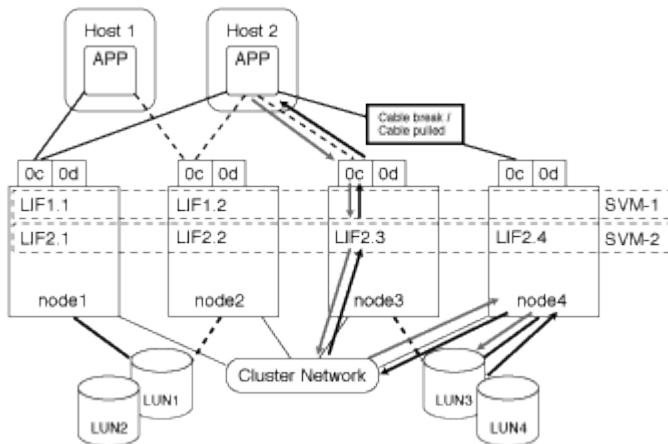

Example of an active or optimized path to a LUN from a host system

In an active or optimized path, the data traffic does not travel over the cluster network; it travels the most direct route to the LUN. The active or optimized path to LUN1 is through LIF1.1 in node1, using physical port 0c. Host 2 has two active or optimized paths, one path to node1, LIF2.1, which is sharing physical port 0c and the other path to node4, LIF2.4, which is using physical port 0c.

Example of an active or unoptimized path (indirect) path to a LUN from a host system

In an active or unoptimized path (indirect) path, the data traffic travels over the cluster network. This issue occurs only if all the active or optimized paths from a host are unavailable to handle traffic. If the path from Host 2 to SVM-2 LIF2.4 is lost, then access to LUN3 and LUN4 traverses the cluster network. Access from Host 2 uses LIF2.3 on node3. Then the traffic enters the cluster network switch and backs up to node4 for access to the LUN3 and LUN4. It will then traverse back over the cluster network switch and then back out through LIF2.3 to Host 2. This active or unoptimized path is used until the path to LIF2.4 is restored or a new LIF is established for SVM-2 on another physical port on node 4.

= Considerations for LIFs in cluster SAN environments

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

You must be aware of certain LIF considerations in a SAN environment.

- Initiators must use Multipath I/O (MPIO) and asymmetric logical unit access(ALUA) for failover capability for clusters in a SAN iSCSI or FC environment because SAN does not support automatic failover for LIFs.
- At least one SAN LIF of the appropriate protocol must be configured on each node that hosts a mapped LUN and the node's HA partner.

You can configure two LIFs per node, one for each fabric being used with FC and to separate Ethernet networks for iSCSI.

- Some options are not applicable for iSCSI or FC.

For example, you cannot use IP addresses with FC.

= Improve VMware VAAI performance for ESX hosts

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ONTAP supports certain VMware vStorage APIs for Array Integration (VAAI) features when the ESX host is running ESX 4.1 or later. These features help offload operations from the ESX host to the storage system and increase the network throughput. The ESX host enables the features automatically in the correct environment.

The VAAI feature supports the following SCSI commands:

- EXTENDED_COPY

This feature enables the host to initiate the transfer of data between the LUNs or within a LUN without involving the host in the data transfer. This results in saving ESX CPU cycles and increasing the network throughput. The extended copy feature, also known as "copy offload," is used in scenarios such as cloning a virtual machine. When invoked by the ESX host, the copy offload feature copies the data within the storage system rather than going through the host network. Copy offload transfers data in the following ways:

- Within a LUN
 - Between LUNs within a volume
 - Between LUNs on different volumes within a storage virtual machine (SVM)
 - Between LUNs on different SVMs within a cluster
- If this feature cannot be invoked, the ESX host automatically uses the standard READ and WRITE commands for the copy operation.

- WRITE_SAME

This feature offloads the work of writing a repeated pattern, such as all zeros, to a storage array. The ESX host uses this feature in operations such as zero-filling a file.

- COMPARE_AND_WRITE

This feature bypasses certain file access concurrency limits, which speeds up operations such as booting up virtual machines.

== Requirements for using the VAAI environment

The VAAI features are part of the ESX operating system and are automatically invoked by the ESX host when you have set up the correct environment.

The environment requirements are as follows:

- The ESX host must be running ESX 4.1 or later.

- The NetApp storage system that is hosting the VMware datastore must be running ONTAP.
- (Copy offload only) The source and the destination of the VMware copy operation must be hosted on the same storage system within the same cluster.

The copy offload feature currently does not support copying data between VMware datastores that are hosted on different storage systems.

== Determine if VAAI features are supported by ESX

To confirm whether the ESX operating system supports the VAAI features, you can check the vSphere Client or use any other means of accessing the host. ONTAP supports the SCSI commands by default.

You can check your ESX host advanced settings to determine whether VAAI features are enabled. The table indicates which SCSI commands correspond to ESX control names.

SCSI command	ESX control name (VAAI feature)
EXTENDED_COPY	HardwareAcceleratedMove
WRITE_SAME	HardwareAcceleratedInit
COMPARE_AND_WRITE	HardwareAcceleratedLocking

= Microsoft Offloaded Data Transfer (ODX)

= Microsoft Offloaded Data Transfer (ODX) overview

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

Microsoft Offloaded Data Transfer (ODX), also known as *copy offload*, enables direct data transfers within a storage device or between compatible storage devices without transferring the data through the host computer.

ONTAP supports ODX for both the SMB and SAN protocols.

In non-ODX file transfers, the data is read from the source and is transferred across the network to the host. The host transfers the data back over the network to the destination. In ODX file transfer, the data is copied directly from the source to the destination without passing through the host.

Because ODX offloaded copies are performed directly between the source and destination, significant performance benefits are realized, including faster copy time, reduced utilization of CPU and memory on the client, and reduced network I/O bandwidth utilization.

For SAN environments, ODX is only available when it is supported by both the host and the storage system. Client computers that support ODX and have ODX enabled automatically and transparently use offloaded file transfer when moving or copying files. ODX is used regardless of whether you drag-and-drop files through Windows Explorer or use command-line file copy commands, or whether a client application initiates file copy requests.

= Requirements for using ODX

```
:icons: font
:relative_path: ./san-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin../media/
```

If you plan to use ODX for copy offloads, you need to be familiar with volume support considerations, system requirements, and software capability requirements.

To use ODX, your system must have the following:

- ONTAP

ODX is automatically enabled in supported versions of ONTAP.

- Minimum source volume of 2 GB

For optimal performance, the source volume should be greater than 260 GB.

- Deduplication

ODX uses deduplication as part of the copy process. If you do not want deduplication on your SVM, you should disable ODX on that SVM.

- ODX support on the Windows client

ODX is supported in Windows Server 2012 or later and in Windows 8 or later. The Interoperability Matrix contains the latest information about supported Windows clients.

[NetApp Interoperability Matrix Tool](#)

- Copy application support for ODX

The application that performs the data transfer must support ODX. Application operations that support ODX include the following:

- Hyper-V management operations, such as creating and converting virtual hard disks (VHDs), managing Snapshot copies, and copying files between virtual machines
- Windows Explorer operations
- Windows PowerShell copy commands
- Windows command prompt copy commands

The Microsoft TechNet Library contains more information about supported ODX applications on Windows servers and clients.

- If you use compressed volumes, the compression group size must be 8K.

32K compression group size is not supported.

ODX does not work with the following volume types:

- Source volumes with capacities of less than 2 GB
- Sparse volumes
- Read-only volumes
- Semi-thick provisioned volumes

= Use cases for ODX

:icons: font

:relative_path: ./san-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You should be aware of the use cases for using ODX on SVMs so that you can determine under what circumstances ODX provides you with performance benefits.

Windows servers and clients that support ODX use copy offload as the default way of copying data across remote servers. If the Windows server or client does not support ODX or the ODX copy offload fails at any point, the copy or move operation falls back to traditional reads and writes for the copy or move operation.

The following use cases support using ODX copies and moves:

- Intra-volume

The source and destination files or LUNs are within the same volume.

- Inter-volume, same node, same SVM

The source and destination files or LUNs are on different volumes that are located on the same node. The data is owned by the same SVM.

- Inter-volume, different nodes, same SVM

The source and destination files or LUNs are on different volumes that are located on different nodes. The data is owned by the same SVM.

- Inter-SVM, same node

The source and destination file or LUNs are on different volumes that are located on the same node. The data is owned by different SVMs.

- Inter-SVM, different nodes

The source and destination file or LUNs are on different volumes that are located on different nodes. The data is owned by different SVMs.

- Inter-cluster

The source and destination LUNs are on different volumes that are located on different nodes across clusters. This is only supported for SAN and does not work for SMB.

There are some additional special use cases:

- With the ONTAP ODX implementation, you can use ODX to copy files between SMB shares and FC or iSCSI attached virtual drives.

You can use Windows Explorer, the Windows CLI or PowerShell, Hyper-V, or other applications that support ODX to copy or move files seamlessly using ODX copy offload between SMB shares and connected LUNs, provided that the SMB shares and LUNs are on the same cluster.

- Hyper-V provides some additional use cases for ODX copy offload:

- You can use ODX copy offload pass-through with Hyper-V to copy data within or across virtual hard disk (VHD) files or to copy data between mapped SMB shares and connected iSCSI LUNs within the same cluster.

This allows copies from guest operating systems to pass through to the underlying storage.

- When creating fixed-sized VHDs, ODX is used for initializing the disk with zeros, using a well-known zeroed token.
- ODX copy offload is used for virtual machine storage migration if the source and destination storage is on the same cluster.

To take advantage of the use cases for ODX copy offload pass-through with Hyper-V, the guest operating system must support ODX and the guest operating system's disks must be SCSI disks backed by storage (either SMB or SAN) that supports ODX. IDE disks on the guest operating system do not support ODX pass-through.

== Special system file requirements

You can delete ODX files found in qtrees. You must not remove or modify any other ODX system files unless you are told by technical support to do so.

When using the ODX feature, there are ODX system files that exist in every volume of the system. These files enable point-in-time representation of data used during the ODX transfer. The following system files are in the root level of each volume that contains LUNs or files to which data was offloaded:

- `.copy-offload` (a hidden directory)
- `.tokens` (file under the hidden `.copy-offload` directory)

You can use the `copy-offload delete-tokens -path dir_path -node node_name` command to delete a qtree containing an ODX file.

= SAN configuration reference

= SAN configuration reference

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The following sections describe supported FC-NVMe, FC, iSCSI, and FCoE topologies for connecting host computers to nodes, and list supported limits for SAN components.

You should use this information in conjunction with basic SAN configuration documentation:

- [SAN administration overview](#)

= Considerations for iSCSI configurations

= Considerations for iSCSI configurations overview

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You should consider several things when setting up your iSCSI configuration.

- You can set up your iSCSI configuration with single nodes or with HA pairs.

Direct connect or the use of Ethernet switches is supported for connectivity. You must create LIFs for both types of connectivity

- You should configure one management LIF for every storage virtual machine (SVM) supporting SAN.
- Selective LUN mapping (SLM) limits the paths that are being utilized in accessing the LUNs owned by an HA pair.

This is the default behavior for LUNs created with ONTAP releases.

- HA pairs are defined as the reporting nodes for the Active/Optimized and the Active/Unoptimized paths that will be used by the host in accessing the LUNs through ALUA.
- It is recommended that all SVMs in ISCSI configurations have a minimum of two LIF's per node in separate Ethernet networks for redundancy and MPIO across multiple paths.
- You need to create one or more iSCSI paths from each node in an HA pair, using logical interfaces (LIFs) to allow access to LUNs that are serviced by the HA pair.

If a node fails, LIFs do not migrate or assume the IP addresses of the failed partner node. Instead, the MPIO software, using ALUA on the host, is responsible for selecting the appropriate paths for LUN access through LIFs.

- VLANs offer specific benefits, such as increased security and improved network reliability that you might want to leverage in iSCSI.

= Ways to configure iSCSI SAN hosts with single nodes

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can configure the iSCSI SAN hosts to connect directly to a single node or by using either one or multiple IP switches. You should determine whether you want a single-switch configuration that is not completely redundant or a multi-switch configuration that is completely redundant.

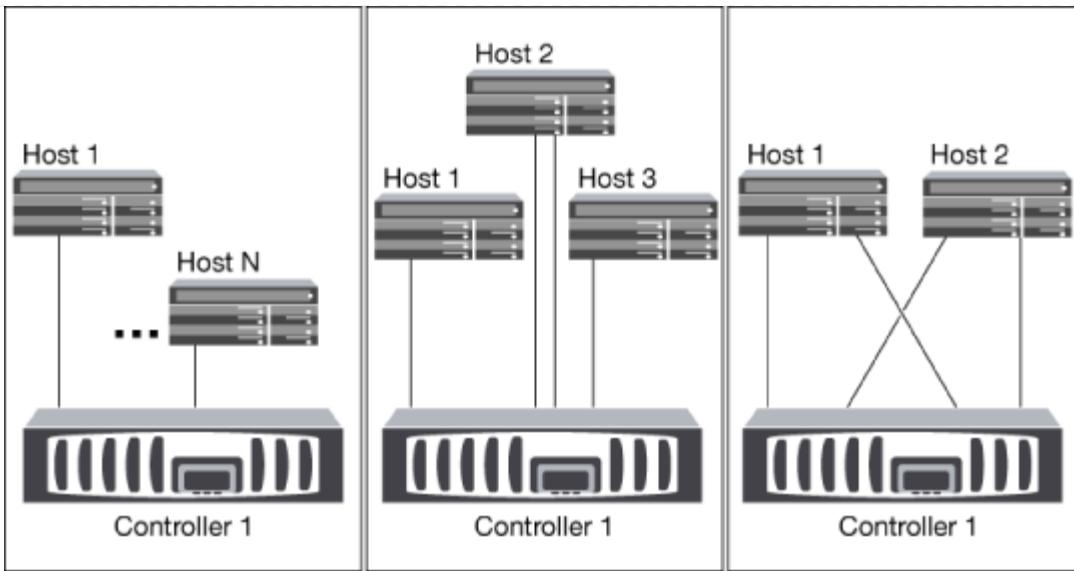

You can configure iSCSI SAN hosts in a direct-attached, single-switch, or multi-switch environment. If there are multiple hosts connecting to the node, each host can be configured with a different operating system. For single and multi-network configurations, the node can have multiple iSCSI connections to the switch, but multipathing software that supports ALUA is required.

If there are multiple paths from the host to the controller, then ALUA must be enabled on the host.

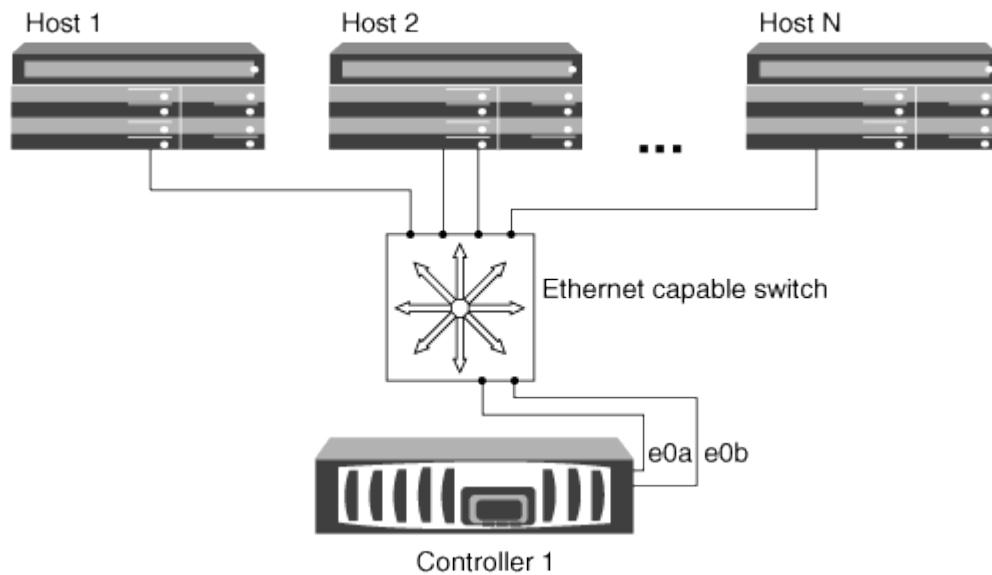

== Direct-attached single-node configurations

In direct-attached configurations, one or more hosts are directly connected to the node.

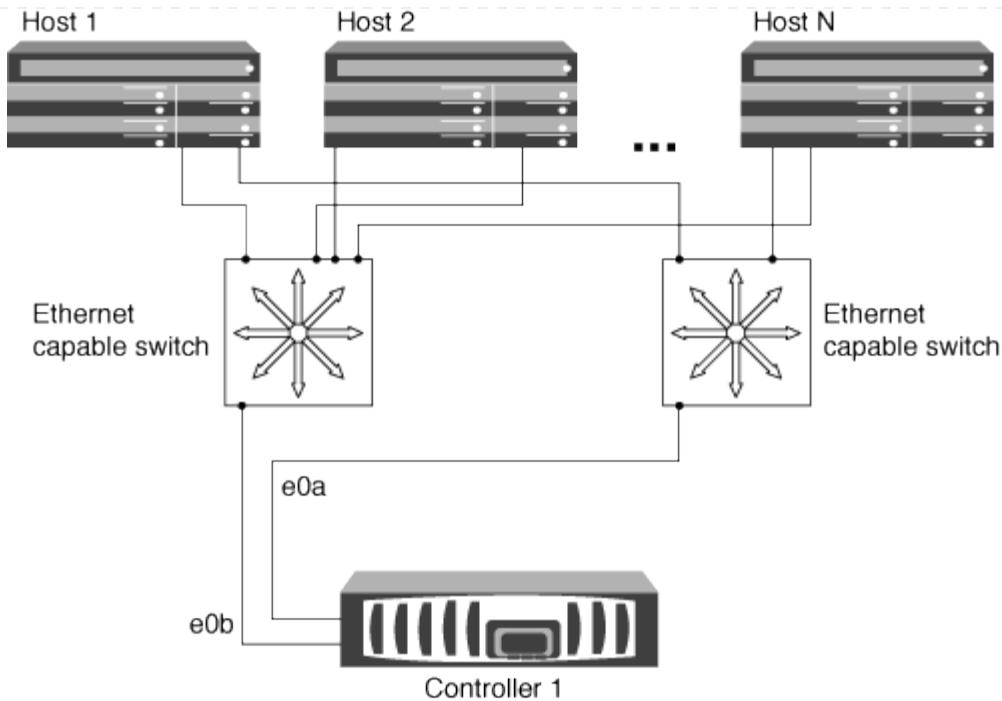

== Single-network single-node configurations

In single-network single-node configurations, one switch connects a single node to one or more hosts. Because there is a single switch, this configuration is not fully redundant.

== Multi-network single-node configurations

In multi-network single-node configurations, two or more switches connect a single node to one or more hosts. Because there are multiple switches, this configuration is fully redundant.

= Ways to configure iSCSI SAN hosts with HA pairs

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

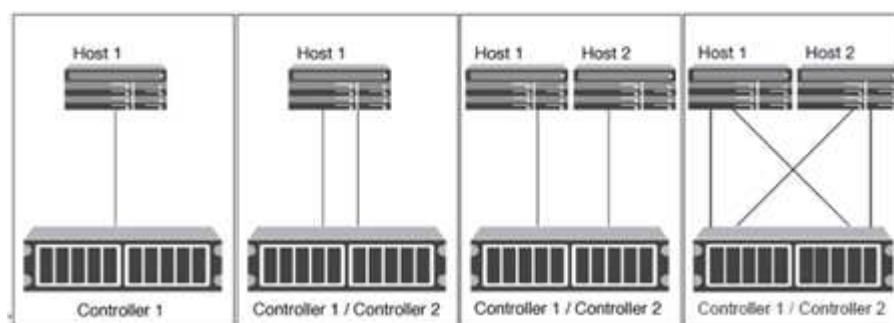

You can configure the iSCSI SAN hosts to connect to dual-node or multi-node configurations by using either one or multiple IP switches. You should determine whether you want a single-switch configuration that is not completely redundant or a multi-switch configuration that is completely redundant.

You can configure iSCSI SAN hosts with single controllers and HA pairs on direct-attached, single-network, or multi-network environments. HA pairs can have multiple iSCSI connections to each switch, but multipathing software that supports ALUA is required on each host. If there are multiple hosts, you can configure each host with a different operating system by checking the NetApp Interoperability Matrix Tool.

[NetApp Interoperability Matrix Tool](#)

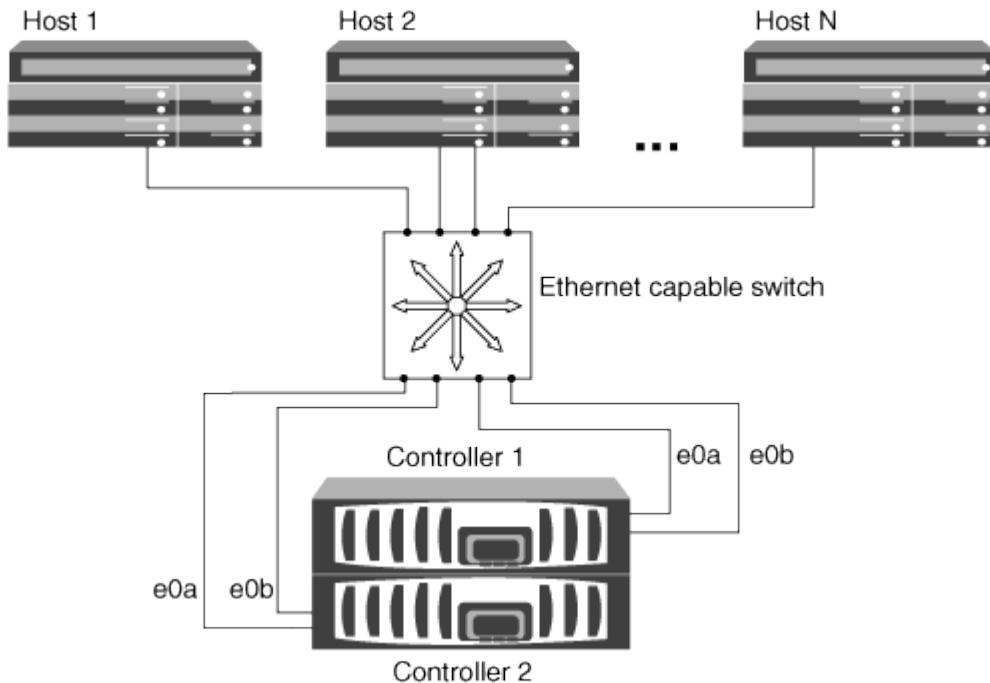

== Direct-attachment

In a direct-attached configuration, one or more hosts are directly connected to the controllers.

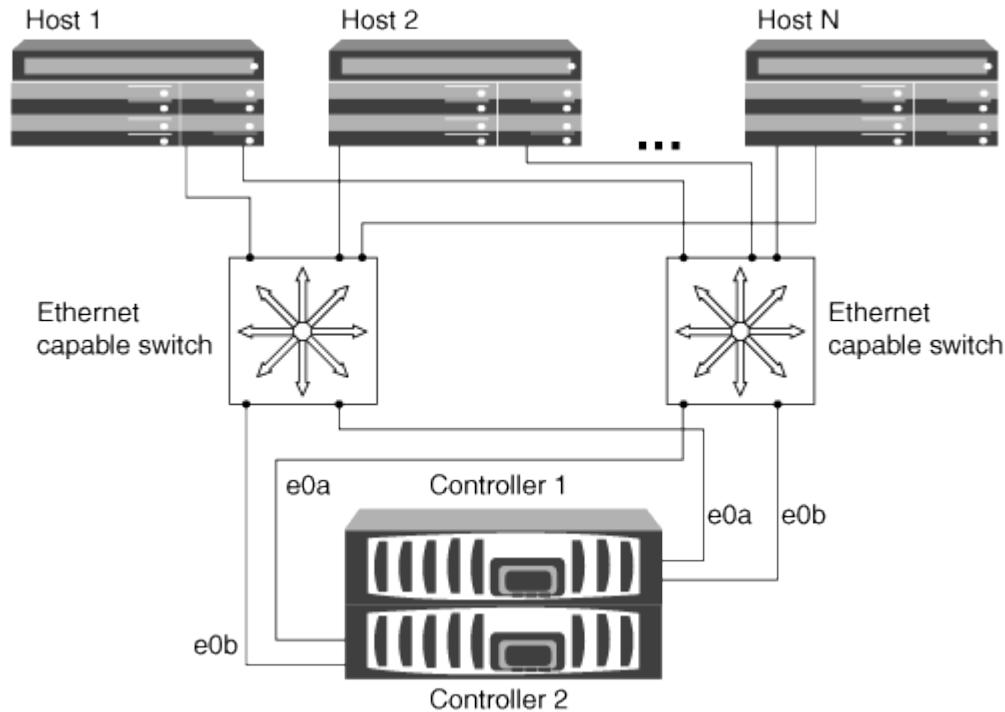

== Single-network HA pairs

In single-network HA pair configurations, one switch connects the HA pair to one or more hosts. Because there is a single switch, this configuration is not fully redundant.

== Multi-network HA pairs

In multi-network HA pair configurations, two or more switches connect the HA pair to one or more hosts. Because there are multiple switches, this configuration is fully redundant.

= Benefits of using VLANs in iSCSI configurations

```
:icons: font
:relative_path: ./san-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

A VLAN consists of a group of switch ports grouped together into a broadcast domain. A VLAN can be on a single switch or it can span multiple switch chassis. Static and dynamic VLANs enable you to increase security, isolate problems, and limit available paths within your IP network infrastructure.

When you implement VLANs in large IP network infrastructures, you derive the following benefits:

- Increased security.

VLANs enable you to leverage existing infrastructure while still providing enhanced security because they limit access between different nodes of an Ethernet network or an IP SAN.

- Improved Ethernet network and IP SAN reliability by isolating problems.
- Reduction of problem resolution time by limiting the problem space.
- Reduction of the number of available paths to a particular iSCSI target port.
- Reduction of the maximum number of paths used by a host.

Having too many paths slows reconnect times. If a host does not have a multipathing solution, you can use VLANs to allow only one path.

== Dynamic VLANs

Dynamic VLANs are MAC address-based. You can define a VLAN by specifying the MAC address of the members you want to include.

Dynamic VLANs provide flexibility and do not require mapping to the physical ports where the device is physically connected to the switch. You can move a cable from one port to another without reconfiguring the VLAN.

== Static VLANs

Static VLANs are port-based. The switch and switch port are used to define the VLAN and its members.

Static VLANs offer improved security because it is not possible to breach VLANs using media access control (MAC) spoofing. However, if someone has physical access to the switch, replacing a cable and reconfiguring the network address can allow access.

In some environments, it is easier to create and manage static VLANs than dynamic VLANs. This is because static VLANs require only the switch and port identifier to be specified, instead of the 48-bit MAC address. In addition, you can label switch port ranges with the VLAN identifier.

= Considerations for FC-NVMe configurations

```
:icons: font
:relative_path: ./san-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

Beginning with ONTAP 9.4, the non-volatile memory express (NVMe) protocol is available for SAN environments. FC-NVMe allows you to run NVMe over an existing

FC network with an AFF system. FC-NVMe uses the same physical setup and zoning practice as traditional FC networks but allows for greater bandwidth, increased IOPs and reduced latency than FC-SCSI.

Supported configurations:

- NVMe is supported on AFF platforms that have 32G FC ports.
- You can set up your FC-NVMe configuration with single nodes or HA pairs using a single fabric or multifabric.
- NVMe is supported on 4-node clusters or smaller.
- NVMe can be the only data protocol on the storage virtual machine (SVM).
- Up to 8 NVMe SVMs are supported per cluster.
- FC-NVMe can be the only data protocol on data LIFs.
- LUNs and namespaces cannot be mixed on the same volume.
- You should configure one management LIF for every SVM supporting SAN.
- The use of heterogeneous FC switch fabrics is not supported, except in the case of embedded blade switches.

Specific exceptions are listed on the [NetApp Interoperability Matrix Tool](#).

- Cascade, partial mesh, full mesh, core-edge, and director fabrics are all industry-standard methods of connecting FC switches to a fabric, and all are supported.

A fabric can consist of one or multiple switches, and the storage controllers can be connected to multiple switches.

Functionality enhancements:

This functionality is supported...	Starting with...
volume move with mapped namespaces	ONTAP 9.6
Namespaces support 512 byte blocks and 4096 byte blocks. 4096 is the default value. 512 should only be used if the host operating system does not support 4096 byte blocks.	ONTAP 9.6
Multipath HA pair failover/giveback	ONTAP 9.5

The following applies only to nodes running ONTAP 9.4:

- NVMe LIFs and namespaces must be hosted on the same node.
- The NVMe service must be created before the NVMe LIF is created.

The following ONTAP features are not supported by NVMe configurations:

- NVMe namespace move
- NVMe namespaces (Copy on Demand)

- Creating namespaces on a volume transitioned from Data ONTAP operating in 7-mode.
- Sync
- Virtual Storage Console
- Application Aware (AppDM/Balanced Placement)

See the [NetApp Hardware Universe](#) for a complete list of NVMe limits.

= Considerations for FC configurations

= Considerations for FC configurations overview

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You should be aware of several things when setting up your FC configuration.

- You can set up your FC configuration with single nodes or HA pairs using a single fabric or multifabric.
- You should configure two FC data LIFs per node.

This creates redundancy and protects against loss of data access.

- You should configure one management LIF for every storage virtual machine (SVM) supporting SAN.
- Multiple hosts, using different operating systems, such as Windows, Linux, or UNIX, can access the storage solution at the same time.

Hosts require that a supported multipathing solution be installed and configured. Supported operating systems and multipathing solutions can be verified on the Interoperability Matrix.

- ONTAP supports single, dual, or multiple node solutions that are connected to multiple physically independent storage fabrics; a minimum of two are recommended for SAN solutions.

This provides redundancy at the fabric and storage system layers. Redundancy is particularly important because these layers typically support many hosts.

- The use of heterogeneous FC switch fabrics is not supported, except in the case of embedded blade switches.

Specific exceptions are listed on the Interoperability Matrix.

- Cascade, partial mesh, full mesh, core-edge, and director fabrics are all industry-standard methods of connecting FC switches to a fabric, and all are supported.

A fabric can consist of one or multiple switches, and the storage controllers can be connected to multiple switches.

Related information

[NetApp Interoperability Matrix Tool](#)

= Ways to configure FC and FC-NVMe SAN hosts with single nodes

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin../media/

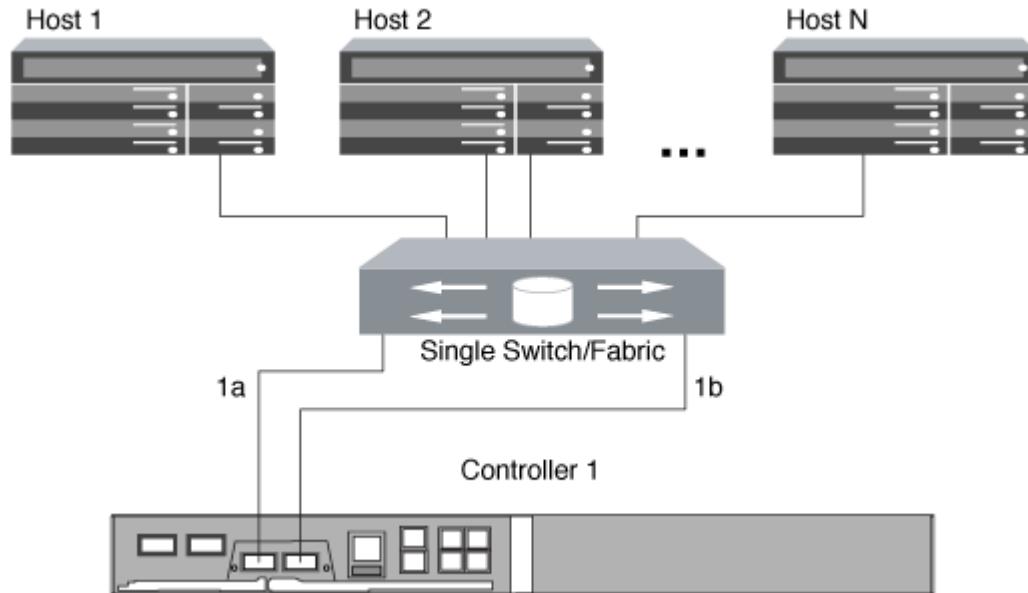

You can configure FC and FC-NVMe SAN hosts with single nodes through one or more fabrics. N-Port ID Virtualization (NPIV) is required and must be enabled on all FC switches in the fabric. You cannot directly attach FC or FC-NVMe SAN hosts to single nodes without using an FC switch.

You can configure FC or FC-NVMe SAN hosts with single nodes through a single fabric or multifabrics. The FC target ports (0a, 0c, 0b, 0d) in the illustrations are examples. The actual port numbers vary depending on the model of your storage node and whether you are using expansion adapters.

== Single-fabric single-node configurations

In single-fabric single-node configurations, there is one switch connecting a single node to one or more hosts. Because there is a single switch, this configuration is not fully redundant. All hardware platforms that support FC and FC-NVMe support single-fabric single-node configurations. However, the FAS2240 platform requires the X1150A-R6 expansion adapter to support a single-fabric single-node configuration.

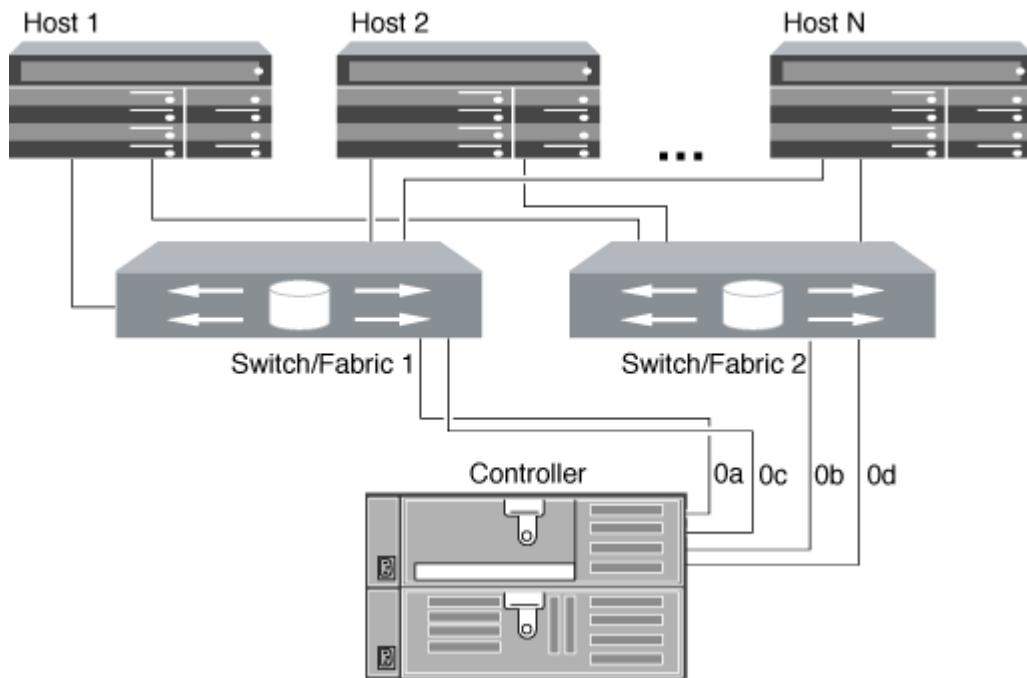

The following figure shows a FAS2240 single-fabric single-node configuration. It shows the storage controllers side by side, which is how they are mounted in the FAS2240-2. For the FAS2240-4, the controllers are mounted one above the other. There is no difference in the SAN configuration for the two models.

== Multifabric single-node configurations

In multifabric single-node configurations, there are two or more switches connecting a single node to one or more hosts. For simplicity, the following figure shows a multifabric single-node configuration with only two fabrics, but you can have two or more fabrics in any multifabric configuration. In this figure, the

storage controller is mounted in the top chassis and the bottom chassis can be empty or can have an IOMX module, as it does in this example.

Related information

[NetApp Technical Report 4684: Implementing and Configuring Modern SANs with NVMe/FC](#)

= Ways to configure FC & FC-NVMe SAN hosts with HA pairs

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

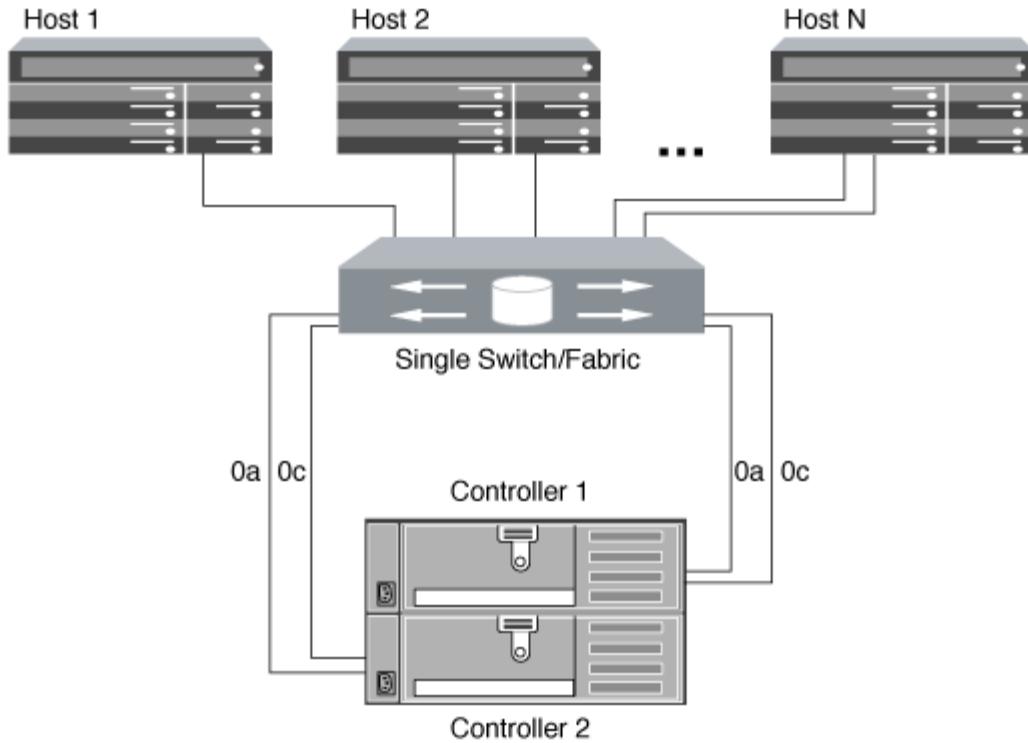

You can configure FC and FC-NVMe SAN hosts to connect to HA pairs through one or more fabrics. You cannot directly attach FC or FC-NVMe SAN hosts to HA pairs without using a switch.

You can configure FC and FC-NVMe SAN hosts with single fabric HA pairs or with multifabric HA pairs. The FC target port numbers (0a, 0c, 0d, 1a, 1b) in the illustrations are examples. The actual port numbers vary depending on the model of your storage node and whether you are using expansion adapters.

== Single-fabric HA pairs

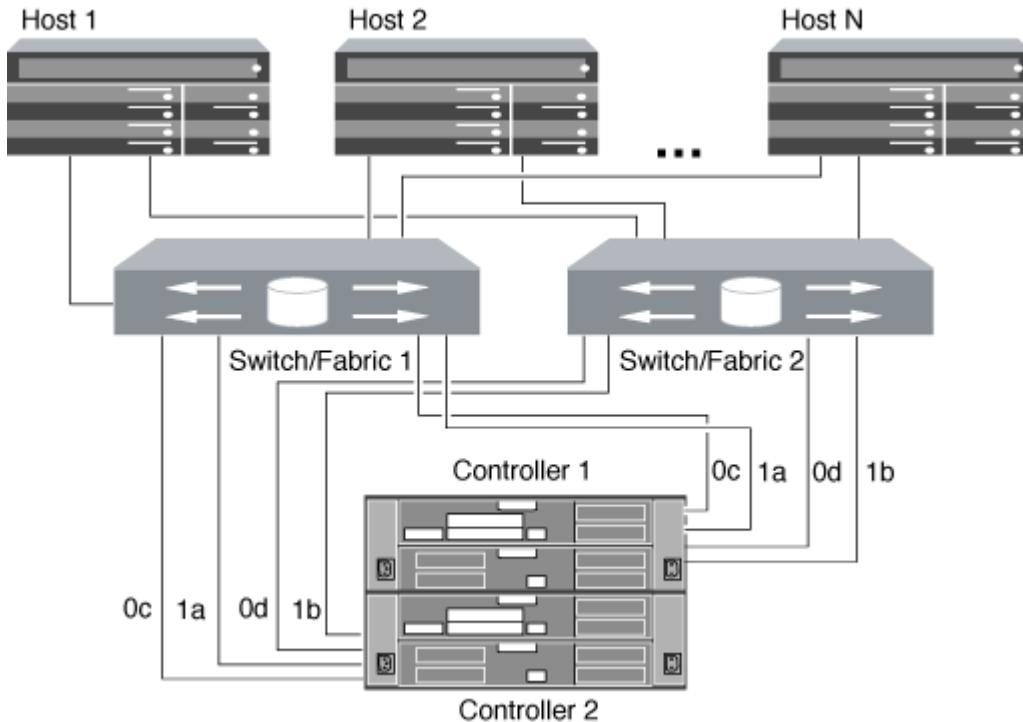

In single-fabric HA pair configurations, there is one fabric connecting both controllers in the HA pair to one or more hosts. Because the hosts and controllers are connected through a single switch, single-fabric HA pairs are not fully redundant.

All platforms that support FC configurations support single-fabric HA pair configurations, except the FAS2240 platform. The FAS2240 platform only supports single-fabric single-node configurations.

== Multifabric HA pairs

In multifabric HA pairs, there are two or more switches connecting HA pairs to one or more hosts. For simplicity, the following multifabric HA pair figure shows only two fabrics, but you can have two or more fabrics in any multifabric configuration:

= FC switch configuration best practices

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/./media/

For best performance, you should consider certain best practices when configuring your FC switch.

A fixed link speed setting is the best practice for FC switch configurations, especially for large fabrics because it provides the best performance for fabric rebuilds and can significantly save time. Although autonegotiation provides the greatest flexibility, FC switch configuration does not always perform as expected, and it adds time to the overall fabric-build sequence.

All of the switches that are connected to the fabric must support N_Port ID virtualization (NPIV) and must have NPIV enabled. ONTAP uses NPIV to present FC targets to a fabric.

For details about which environments are supported, see the [NetApp Interoperability Matrix Tool](#).

For FC and iSCSI best practices, see [Best Practices for Scalable SAN - ONTAP 9](#).

= Supported number of FC hop counts

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/./media/

The maximum supported FC hop count between a host and storage system depends on the switch supplier and storage system support for FC configurations.

The hop count is defined as the number of switches in the path between the initiator (host) and target (storage system). Cisco also refers to this value as the *diameter of the SAN fabric*.

Switch supplier	Supported hop count
Brocade	7 for FC5 for FCoE
Cisco	7 for FCUp to 3 of the switches can be FCoE switches.

[NetApp Downloads: Cisco Scalability Matrix Documents](#)

= FC target port supported speeds

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/./media/

FC target ports can be configured to run at different speeds. You should set the target port speed to match the speed of the device to which it connects. All target ports used by a given host should be set to the same speed. FC target ports can be used for FC-NVMe configurations in the exact same way they are used for FC configurations.

You should set the target port speed to match the speed of the device to which it connects instead of

using autonegotiation. A port that is set to autonegotiation can take longer to reconnect after a takeover/giveback or other interruption.

You can configure onboard ports and expansion adapters to run at the following speeds. Each controller and expansion adapter port can be configured individually for different speeds as needed.

4 Gb ports	8 Gb ports	16 Gb ports	32 Gb ports
<ul style="list-style-type: none">• 4 Gb• 2 Gb• 1 Gb	<ul style="list-style-type: none">• 8 Gb• 4 Gb• 2 Gb	<ul style="list-style-type: none">• 16 Gb• 8 Gb• 4 Gb	<ul style="list-style-type: none">• 32 Gb• 16 Gb• 8 Gb

UTA2 ports can use an 8 Gb SFP+ adapter to support 8, 4, and 2 Gb speeds, if required.

= FC Target port configuration recommendations

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

For best performance and highest availability, you should use the recommended FC target port configuration.

The following table shows the preferred port usage order for onboard FC and FC-NVMe target ports. For expansion adapters, the FC ports should be spread so that they do not use the same ASIC for connectivity. The preferred slot order is listed in [NetApp Hardware Universe](#) for the version of ONTAP software used by your controller.

FC-NVMe is supported on the following models:

- AFF A300

The AFF A300 onboard ports do not support FC-NVMe.

- AFF A700
- AFF A700s
- AFF A800

The FAS22xx and FAS2520 systems do not have onboard FC ports and do not support add-on adapters.

Controller	Port pairs with shared ASIC	Number of target ports: Preferred ports
FAS9000, AFF A700, AFF A700s and AFF A800	None	All data ports are on expansion adapters. See NetApp Hardware Universe for more information.

Controller	Port pairs with shared ASIC	Number of target ports: Preferred ports
8080, 8060 and 8040	0e+0f 0g+0h	1: 0e 2: 0e, 0g 3: 0e, 0g, 0h 4: 0e, 0g, 0f, 0h
FAS8200 and AFF A300	0g+0h	1: 0g 2: 0g, 0h
8020	0c+0d	1: 0c 2: 0c, 0d
62xx	0a+0b 0c+0d	1: 0a 2: 0a, 0c 3: 0a, 0c, 0b 4: 0a, 0c, 0b, 0d
32xx	0c+0d	1: 0c 2: 0c, 0d

= Manage systems with FC adapters

= Managing systems with FC adapters overview

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

Commands are available to manage onboard FC adapters and FC adapter cards. These commands can be used to configure the adapter mode, display adapter information, and change the speed.

Most storage systems have onboard FC adapters that can be configured as initiators or targets. You can also use FC adapter cards configured as initiators or targets. Initiators connect to back-end disk shelves,

and possibly foreign storage arrays (FlexArray). Targets connect only to FC switches. Both the FC target HBA ports and the switch port speed should be set to the same value and should not be set to auto.

= Commands for managing FC adapters

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can use FC commands to manage FC target adapters, FC initiator adapters, and onboard FC adapters for your storage controller. The same commands are used to manage FC adapters for the FC protocol and the FC-NVMe protocol.

FC initiator adapter commands work only at the node level. You must use the `run -node node_name` command before you can use the FC initiator adapter commands.

== Commands for managing FC target adapters

If you want to...	Use this command...
Display FC adapter information on a node	<code>network fcp adapter show</code>
Modify FC target adapter parameters	<code>network fcp adapter modify</code>
Display FC protocol traffic information	<code>run -node node_name sysstat -f</code>
Display how long the FC protocol has been running	<code>run -node node_name uptime</code>
Display adapter configuration and status	<code>run -node node_name sysconfig -v adapter</code>
Verify which expansion cards are installed and whether there are any configuration errors	<code>run -node node_name sysconfig -ac</code>
View a man page for a command	<code>man command_name</code>

== Commands for managing FC initiator adapters

If you want to...	Use this command...
Display information for all initiators and their adapters in a node	<code>run -node node_name storage show adapter</code>
Display adapter configuration and status	<code>run -node node_name sysconfig -v adapter</code>
Verify which expansion cards are installed and whether there are any configuration errors	<code>run -node node_name sysconfig -ac</code>

== Commands for managing onboard FC adapters

If you want to...	Use this command...
Display the status of the onboard FC ports	system node hardware unified-connect show

= Configure FC adapters for initiator mode
:icons: font
:relative_path: ./san-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can configure individual FC ports of onboard adapters and certain FC adapter cards for initiator mode. Initiator mode is used to connect the ports to tape drives, tape libraries, or third-party storage with FlexArray Virtualization or Foreign LUN Import (FLI).

What you'll need

- LIFs on the adapter must be removed from any port sets of which they are members.
- All LIF's from every storage virtual machine (SVM) using the physical port to be modified must be migrated or destroyed before changing the personality of the physical port from target to initiator.

About this task

Each onboard FC port can be individually configured as an initiator or a target. Ports on certain FC adapters can also be individually configured as either a target port or an initiator port, just like the onboard FC ports. A list of adapters that can be configured for target mode is available in [NetApp Hardware Universe](#).

NVMe/FC does support initiator mode.

Steps

1. Remove all LIFs from the adapter:

```
network interface delete -vserver SVM_name -lif lif_name, lif_name
```

2. Take your adapter offline:

```
network fcp adapter modify -node node_name -adapter adapter_port -status -admin down
```

If the adapter does not go offline, you can also remove the cable from the appropriate adapter port on the system.

3. Change the adapter from target to initiator:

```
system hardware unified-connect modify -t initiator adapter_port
```

4. Reboot the node hosting the adapter you changed.

5. Verify that the FC ports are configured in the correct state for your configuration:

```
system hardware unified-connect show
```

6. Bring the adapter back online:

```
node run -node node_name storage enable adapter adapter_port
```

= Configure FC adapters for target mode
:icons: font
:relative_path: ./san-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can configure individual FC ports of onboard adapters and certain FC adapter cards for target mode. Target mode is used to connect the ports to FC initiators.

About this task

Each onboard FC port can be individually configured as an initiator or a target. Ports on certain FC adapters can also be individually configured as either a target port or an initiator port, just like the onboard FC ports. A list of adapters that can be configured for target mode is available in the [NetApp Hardware Universe](#).

The same steps are used when configuring FC adapters for the FC protocol and the FC-NVMe protocol. However, only certain FC adapters support FC-NVMe. See the [NetApp Hardware Universe](#) for a list of adapters that support the FC-NVMe protocol.

Steps

1. Take the adapter offline:

```
node run -node node_name storage disable adapter adapter_name
```

If the adapter does not go offline, you can also remove the cable from the appropriate adapter port on the system.

2. Change the adapter from initiator to target:

```
system node unified-connect modify -t target -node node_name
```

3. Reboot the node hosting the adapter you changed.

4. Verify that the target port has the correct configuration:

```
network fcp adapter show -node node_name
```

5. Bring your adapter online:

```
network fcp adapter modify -node node_name -adapter adapter_port -state up
```

= Display information about an FC target adapter
:icons: font
:relative_path: ./san-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can use the `network fcp adapter show` command to display system configuration and adapter information for any FC adapter in the system.

Step

1. Display information about the FC adapter by using the `network fcp adapter show` command.

The output displays system configuration information and adapter information for each slot that is used.

```
network fcp adapter show -instance -node node1 -adapter 0a
```

= Change the FC adapter speed

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You should set your adapter target port speed to match the speed of the device to which it connects, instead of using autonegotiation. A port that is set to autonegotiation can take longer time to reconnect after a takeover/giveback or other interruption.

What you'll need

All LIFs that use this adapter as their home port must be offline.

About this task

Because this task encompasses all storage virtual machines (SVMs) and all LIFs in a cluster, you must use the `-home-port` and `-home-lif` parameters to limit the scope of this operation. If you do not use these parameters, the operation applies to all LIFs in the cluster, which might not be desirable.

Steps

1. Take all of the LIFs on this adapter offline:

```
network interface modify -vserver * -lif * { -home-node node1 -home-port 0c  
} -status-admin down
```

2. Take the adapter offline:

```
network fcp adapter modify -node node1 -adapter 0c -state down
```

If the adapter does not go offline, you can also remove the cable from the appropriate adapter port on the system.

3. Determine the maximum speed for the port adapter:

```
fcp adapter show -instance
```

You cannot modify the adapter speed beyond the maximum speed.

4. Change the adapter speed:

```
network fcp adapter modify -node node1 -adapter 0c -speed 16
```

5. Bring the adapter online:

```
network fcp adapter modify -node node1 -adapter 0c -state up
```

6. Bring all of the LIFs on the adapter online:

```
network interface modify -vserver * -lif * { -home-node node1 -home-port 0c
} -status-admin up
```

= Supported FC ports

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The number of onboard FC ports and CNA/UTA2 ports configured for FC varies based on the model of the controller. FC ports are also available through supported FC target expansion adapters or additional UTA2 cards configured with FC SFP+ adapters.

== Onboard FC, UTA, and UTA2 ports

- Onboard ports can be individually configured as either target or initiator FC ports.
- The number of onboard FC ports differs depending on controller model.

The [NetApp Hardware Universe](#) contains a complete list of onboard FC ports on each controller model.

- FC ports are only available on FAS2240 systems through the X1150A-R6 expansion adapter.

FAS2220 and FAS2520 systems do not support FC.

== Target expansion adapter FC ports

- Available target expansion adapters differ depending on controller model.

The [NetApp Hardware Universe](#) contains a complete list of target expansion adapters for each controller model.

- The ports on some FC expansion adapters are configured as initiators or targets at the factory and cannot be changed.

Others can be individually configured as either target or initiator FC ports, just like the onboard FC ports. A complete list is available in [NetApp Hardware Universe](#).

= Prevent loss of connectivity when using the X1133A-R6 adapter

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can prevent loss of connectivity during a port failure by configuring your system with redundant paths to separate X1133A-R6 HBAs.

The X1133A-R6 HBA is a 4-port, 16 Gb FC adapter consisting of two 2-port pairs. The X1133A-R6 adapter can be configured as target mode or initiator mode. Each 2-port pair is supported by a single ASIC (for example, Port 1 and Port 2 on ASIC 1 and Port 3 and Port 4 on ASIC 2). Both ports on a single ASIC must be configured to operate in the same mode, either target mode or initiator mode. If an error

occurs with the ASIC supporting a pair, both ports in the pair go offline.

To prevent this loss of connectivity, you configure your system with redundant paths to separate X1133A-R6 HBAs, or with redundant paths to ports supported by different ASICs on the HBA.

= Manage X1143A-R6 adapters

= Supported port configurations for X1143A-R6 adapters overview

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

By default the X1143A-R6 adapter is configured in FC target mode, but you can configure its ports as either 10 Gb Ethernet and FCoE (CNA) ports or as 16 Gb FC initiator or target ports. This requires different SFP+ adapters.

When configured for Ethernet and FCoE, X1143A-R6 adapters support concurrent NIC and FCoE target traffic on the same 10-GBE port. When configured for FC, each two-port pair that shares the same ASIC can be individually configured for FC target or FC initiator mode. This means that a single X1143A-R6 adapter can support FC target mode on one two-port pair and FC initiator mode on another two-port pair. Port pairs connected to the same ASIC must be configured in the same mode.

In FC mode, the X1143A-R6 adapter behaves just like any existing FC device with speeds up to 16 Gbps. In CNA mode, you can use the X1143A-R6 adapter for concurrent NIC and FCoE traffic sharing the same 10 GbE port. CNA mode only supports FC target mode for the FCoE function.

= Configure the ports

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

To configure the unified target adapter (X1143A-R6), you must configure the two adjacent ports on the same chip in the same personality mode.

Steps

1. Configure the ports as needed for Fibre Channel (FC) or Converged Network Adapter (CNA) using the `system node hardware unified-connect modify` command.
2. Attach the appropriate cables for FC or 10 Gb Ethernet.
3. Verify that you have the correct SFP+ installed:

```
network fcp adapter show -instance -node -adapter
```

For CNA, you should use a 10Gb Ethernet SFP. For FC, you should either use an 8 Gb SFP or a 16 Gb SFP, based on the FC fabric being connected to.

= Change the UTA2 port from CNA mode to FC mode

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You should change the UTA2 port from Converged Network Adapter (CNA) mode to Fibre Channel (FC) mode to support the FC initiator and FC target mode. You should

change the personality from CNA mode to FC mode when you need to change the physical medium that connects the port to its network.

Steps

1. Take the adapter offline:

```
network fcp adapter modify -node node_name -adapter adapter_name -status  
-admin down
```

2. Change the port mode:

```
ucadmin modify -node node_name -adapter adapter_name -mode fcp
```

3. Reboot the node, and then bring the adapter online:

```
network fcp adapter modify -node node_name -adapter adapter_name -status  
-admin up
```

4. Notify your admin or VIF manager to delete or remove the port, as applicable:

- If the port is used as a home port of a LIF, is a member of an interface group (ifgrp), or hosts VLANs, then an admin should do the following:
 - i. Move the LIFs, remove the port from the ifgrp, or delete the VLANs, respectively.
 - ii. Manually delete the port by running the `network port delete` command.

If the `network port delete` command fails, the admin should address the errors, and then run the command again.

- If the port is not used as the home port of a LIF, is not a member of an ifgrp, and does not host VLANs, then the VIF manager should remove the port from its records at the time of reboot.

If the VIF manager does not remove the port, then the admin must remove it manually after the reboot by using the `network port delete` command.

```

5. Verify that you have the correct SFP+ installed:

```
network fcp adapter show -instance -node -adapter
```

For CNA, you should use a 10Gb Ethernet SFP. For FC, you should either use an 8 Gb SFP or a 16 Gb SFP, before changing the configuration on the node.

= Change the CNA/UTA2 target adapter optical modules

:icons: font
:relative_path: ./san-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

You should change the optical modules on the unified target adapter (CNA/UTA2) to support the personality mode you have selected for the adapter.

Steps

1. Verify the current SFP+ used in the card. Then, replace the current SFP+ with the appropriate SFP+ for the preferred personality (FC or CNA).
2. Remove the current optical modules from the X1143A-R6 adapter.
3. Insert the correct modules for your preferred personality mode (FC or CNA) optics.
4. Verify that you have the correct SFP+ installed:

```
network fcp adapter show -instance -node -adapter
```

Supported SFP+ modules and Cisco-branded Copper (Twinax) cables are listed in the [NetApp Hardware Universe](#).

= View adapter settings

:icons: font
:relative_path: ./san-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

To view the settings for your unified target adapter (X1143A-R6), you must run the system hardware unified-connect show command to display all modules on your controller.

Steps

1. Boot your controller without the cables attached.
2. Run the system hardware unified-connect show command to see the port configuration and modules.
3. View the port information before configuring the CNA and ports.

= Ways to Configure FCoE

= Ways to Configure FCoE overview

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

FCoE can be configured in various ways using FCoE switches. Direct-attached configurations are not supported in FCoE.

All FCoE configurations are dual-fabric, fully redundant, and require host-side multipathing software. In all FCoE configurations, you can have multiple FCoE and FC switches in the path between the initiator and target, up to the maximum hop count limit. To connect switches to each other, the switches must run a firmware version that supports Ethernet ISLs. Each host in any FCoE configuration can be configured with a different operating system.

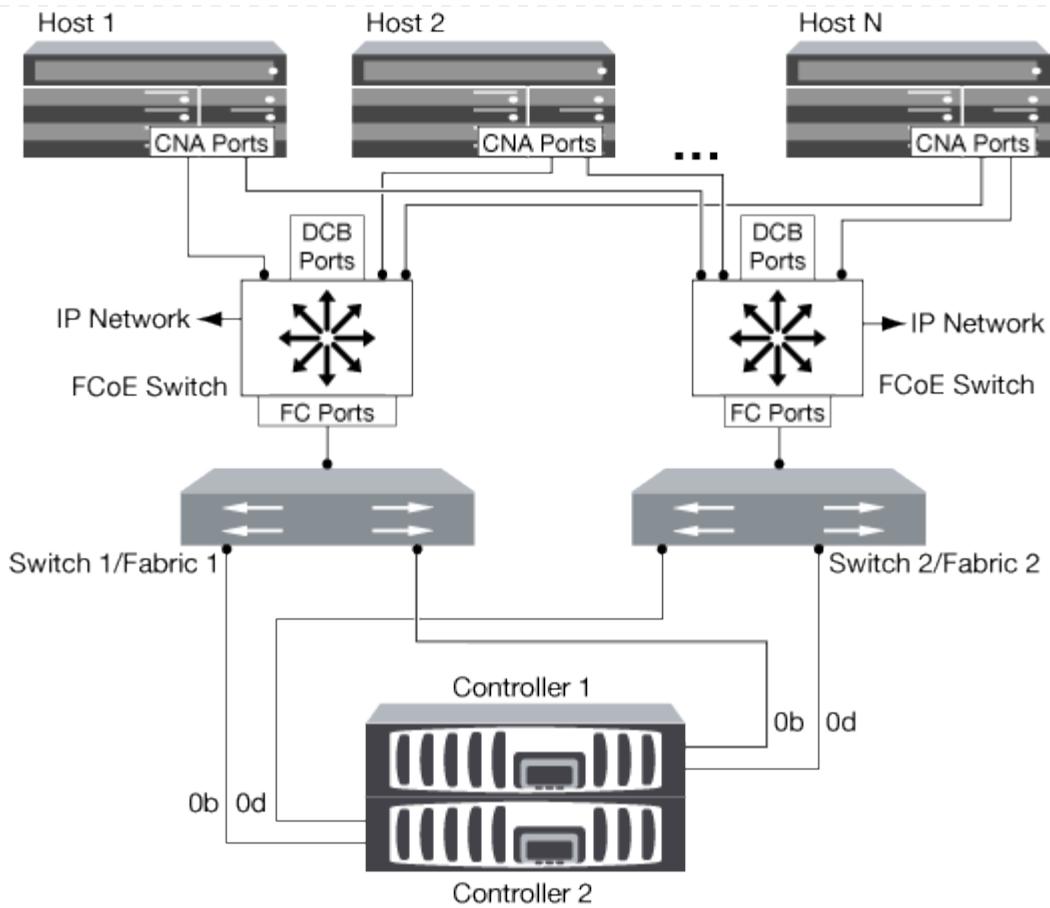

FCoE configurations require Ethernet switches that explicitly support FCoE features. FCoE configurations are validated through the same interoperability and quality assurance process as FC switches. Supported configurations are listed in the Interoperability Matrix. Some of the parameters included in these supported configurations are the switch model, the number of switches that can be deployed in a single fabric, and the supported switch firmware version.

The FC target expansion adapter port numbers in the illustrations are examples. The actual port numbers might vary, depending on the expansion slots in which the FCoE target expansion adapters are installed.

== FCoE initiator to FC target

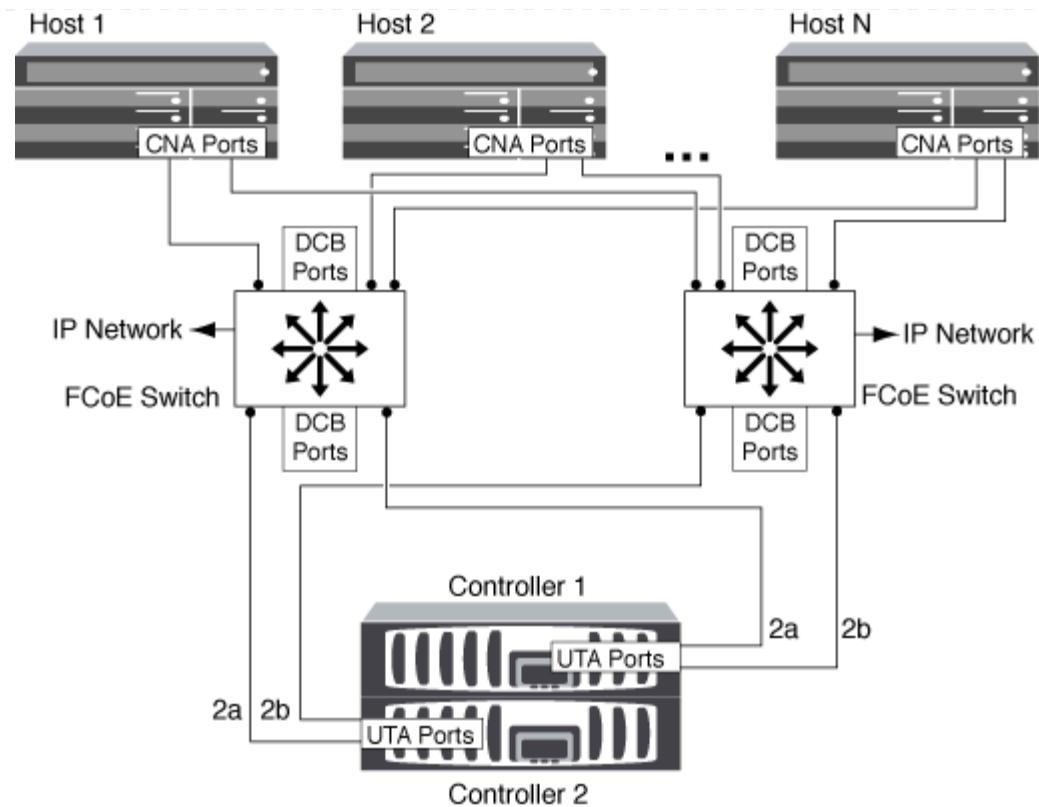

Using FCoE initiators (CNAs), you can connect hosts to both controllers in an HA pair through FCoE switches to FC target ports. The FCoE switch must also have FC ports. The host FCoE initiator always connects to the FCoE switch. The FCoE switch can connect directly to the FC target or can connect to the FC target through FC switches.

The following illustration shows host CNAs connecting to an FCoE switch, and then to an FC switch before connecting to the HA pair:

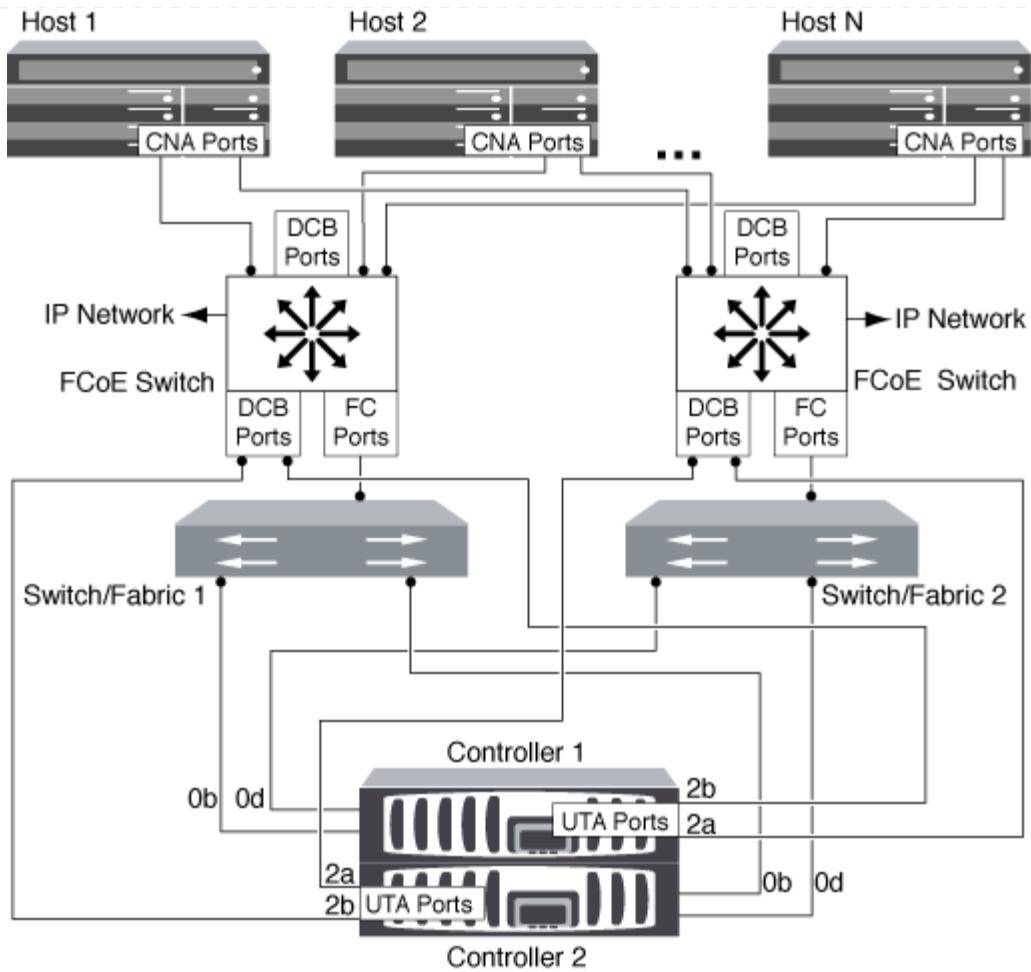

== FCoE initiator to FCoE target

Using host FCoE initiators (CNAs), you can connect hosts to both controllers in an HA pair to FCoE target ports (also called UTAs or UTA2s) through FCoE switches.

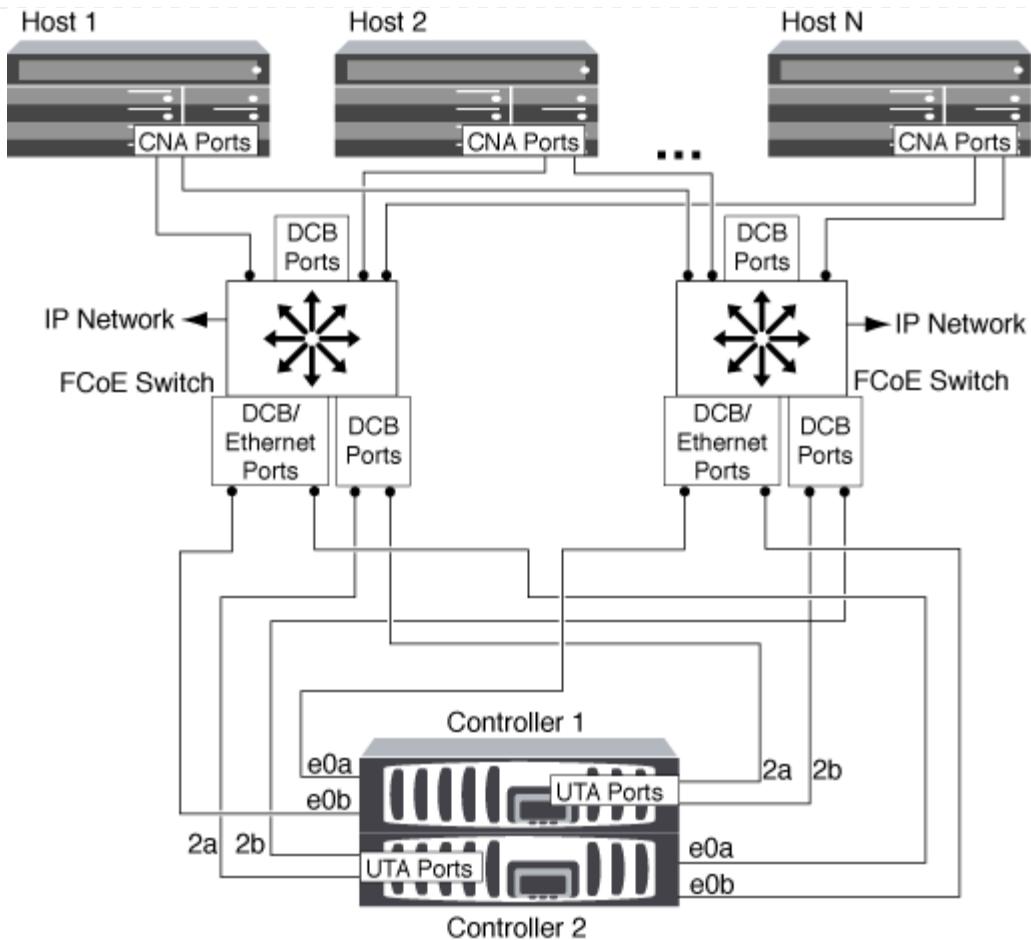

== FCoE initiator to FCoE and FC targets

Using host FCoE initiators (CNAs), you can connect hosts to both controllers in an HA pair to FCoE and FC target ports (also called UTAs or UTA2s) through FCoE switches.

== FCoE mixed with IP storage protocols

Using host FCoE initiators (CNAs), you can connect hosts to both controllers in an HA pair to FCoE target ports (also called UTAs or UTA2s) through FCoE switches. FCoE ports cannot use traditional link aggregation to a single switch. Cisco switches support a special type of link aggregation (Virtual Port Channel) that does support FCoE. A Virtual Port Channel aggregates individual links to two switches. You can also use Virtual Port Channels for other Ethernet traffic. Ports used for traffic other than FCoE, including NFS, SMB, iSCSI, and other Ethernet traffic, can use regular Ethernet ports on the FCoE switches.

= FCoE initiator and target combinations

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin../media/

Certain combinations of FCoE and traditional FC initiators and targets are supported.

== FCoE initiators

You can use FCoE initiators in host computers with both FCoE and traditional FC targets in storage controllers. The host FCoE initiator must connect to an FCoE DCB (data center bridging) switch; direct connection to a target is not supported.

The following table lists the supported combinations:

Initiator	Target	Supported?
FC	FC	Yes
FC	FCoE	Yes
FCoE	FC	Yes
FCoE	FCoE	Yes

== FCoE targets

You can mix FCoE target ports with 4-Gb, 8-Gb, or 16-Gb FC ports on the storage controller regardless of whether the FC ports are add-in target adapters or onboard ports. You can have both FCoE and FC target adapters in the same storage controller.

The rules for combining onboard and expansion FC ports still apply.

= FCoE supported hop count

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The maximum supported Fibre Channel over Ethernet (FCoE) hop count between a host and storage system depends on the switch supplier and storage system support for FCoE configurations.

The hop count is defined as the number of switches in the path between the initiator (host) and target (storage system). Documentation from Cisco Systems also refers to this value as the *diameter of the SAN fabric*.

For FCoE, you can have FCoE switches connected to FC switches.

For end-to-end FCoE connections, the FCoE switches must be running a firmware version that supports Ethernet inter-switch links (ISLs).

The following table lists the maximum supported hop counts:

Switch supplier	Supported hop count
Brocade	7 for FC
	5 for FCoE
Cisco	7 Up to 3 of the switches can be FCoE switches.

= Fibre Channel and FCoE zoning

= Fibre Channel and FCoE zoning overview

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

An FC, FC-NVMe or FCoE zone is a logical grouping of one or more ports within a fabric. For devices to be able see each other, connect, create sessions with one another, and communicate, both ports need to have a common zone membership. Single initiator zoning is recommended.

== Reasons for zoning

- Zoning reduces or eliminates *crosstalk* between initiator HBAs.

This occurs even in small environments and is one of the best arguments for implementing zoning. The logical fabric subsets created by zoning eliminate crosstalk problems.

- Zoning reduces the number of available paths to a particular FC, FC-NVMe, or FCoE port and reduces the number of paths between a host and a particular LUN that is visible.

For example, some host OS multipathing solutions have a limit on the number of paths they can manage. Zoning can reduce the number of paths that an OS multipathing driver sees. If a host does not have a multipathing solution installed, you need to verify that only one path to a LUN is visible by using either zoning in the fabric or a combination of Selective LUN Mapping (SLM) and portsets in the SVM.

- Zoning increases security by limiting access and connectivity to end-points that share a common zone.

Ports that have no zones in common cannot communicate with one another.

- Zoning improves SAN reliability by isolating problems that occur and helps to reduce problem resolution time by limiting the problem space.

== Recommendations for zoning

- You should implement zoning any time, if four or more hosts are connected to a SAN or if SLM is not implemented on the nodes to a SAN.
- Although World Wide Node Name zoning is possible with some switch vendors, World Wide Port Name zoning is required to properly define a specific port and to use NPIV effectively.
- You should limit the zone size while still maintaining manageability.

Multiple zones can overlap to limit size. Ideally, a zone is defined for each host or host cluster.

- You should use single-initiator zoning to eliminate crosstalk between initiator HBAs.

= World Wide Name-based zoning

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Zoning based on World Wide Name (WWN) specifies the WWN of the members to be included within the zone. When zoning in ONTAP, you must use World Wide Port Name (WWPN) zoning.

WWPN zoning provides flexibility because access is not determined by where the device is physically connected to the fabric. You can move a cable from one port to another without reconfiguring zones.

For Fibre Channel paths to storage controllers running ONTAP, be sure the FC switches are zoned using the WWPNs of the target logical interfaces (LIFs), not the WWPNs of the physical ports on the node. For more information on LIFs, see the *ONTAP Network Management Guide*.

[Network management](#)

= Individual zones

:icons: font

```
:relative_path: ./san-config/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

In the recommended zoning configuration, there is one host initiator per zone. The zone consists of the host initiator port and one or more target LIFs on the storage nodes that are providing access to the LUNs up to the desired number of paths per target. This means that hosts accessing the same nodes cannot see each other's ports, but each initiator can access any node.

You should add all LIF's from the storage virtual machine (SVM) into the zone with the host initiator. This allows you to move volumes or LUNs without editing your existing zones or creating new zones.

For Fibre Channel paths to nodes running ONTAP, be sure that the FC switches are zoned using the WWPNs of the target logical interfaces (LIFs), not the WWPNs of the physical ports on the node. The WWPNs of the physical ports start with "50" and the WWPNs of the LIFs start with "20".

```
= Single-fabric zoning  
:icons: font  
:relative_path: ./san-config/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

In a single-fabric configuration, you can still connect each host initiator to each storage node. Multipathing software is required on the host to manage multiple paths. Each host should have two initiators for multipathing to provide resiliency in the solution.

Each initiator should have a minimum of one LIF from each node that the initiator can access. The zoning should allow at least one path from the host initiator to the HA pair of nodes in the cluster to provide a path for LUN connectivity. This means that each initiator on the host might only have one target LIF per node in its zone configuration. If there is a requirement for multipathing to the same node or multiple nodes in the cluster, then each node will have multiple LIFs per node in its zone configuration. This enables the host to still access its LUNs if a node fails or a volume containing the LUN is moved to a different node. This also requires the reporting nodes to be set appropriately.

Single-fabric configurations are supported, but are not considered highly available. The failure of a single component can cause loss of access to data.

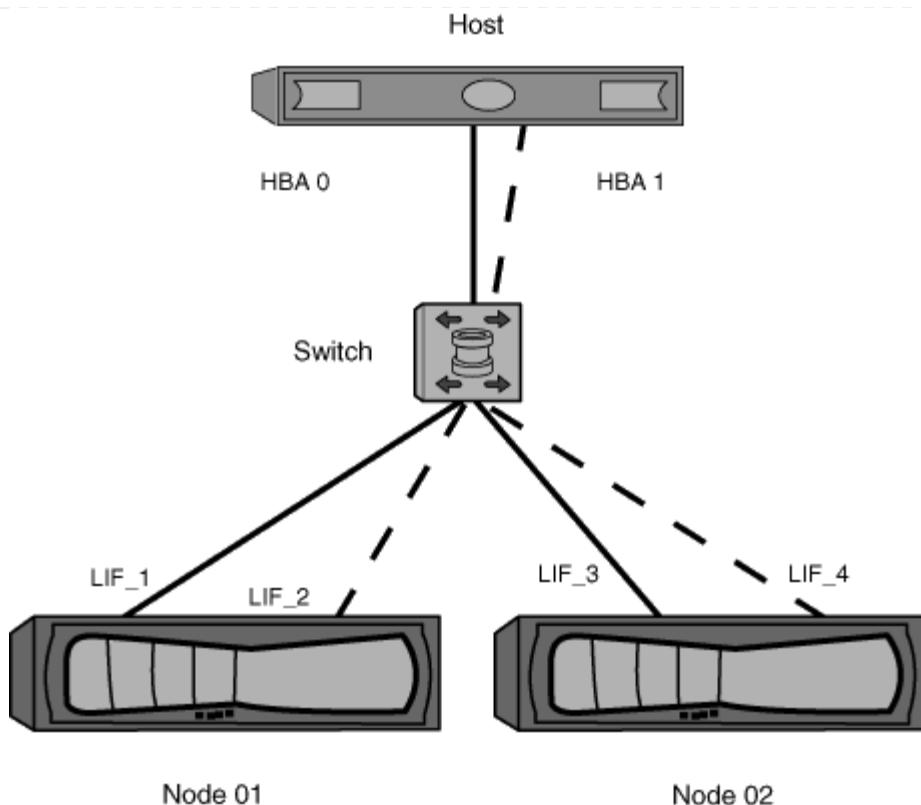

In the following figure, the host has two initiators and is running multipathing software. There are two zones:

The naming convention used in this figure is just a recommendation of one possible naming convention that you can choose to use for your ONTAP solution.

- Zone 1: HBA 0, LIF_1, and LIF_3
- Zone 2: HBA 1, LIF_2, and LIF_4

If the configuration included more nodes, the LIFs for the additional nodes would be included in these zones.

In this example, you could also have all four LIFs in each zone. In that case, the zones would be as follows:

- Zone 1: HBA 0, LIF_1, LIF_2, LIF_3, and LIF_4
- Zone 2: HBA 1, LIF_1, LIF_2, LIF_3, and LIF_4

The host operating system and multipathing software have to support the number of supported paths that are being used to access the LUNs on the nodes. To determine the number of paths used to access the LUNs on nodes, see the SAN configuration limits section.

Related information

[NetApp Hardware Universe](#)

= Dual-fabric HA pair zoning

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

In dual-fabric configurations, you can connect each host initiator to each cluster node. Each host initiator uses a different switch to access the cluster nodes. Multipathing software is required on the host to manage multiple paths.

Dual-fabric configurations are considered high availability because access to data is maintained if a single component fails.

In the following figure, the host has two initiators and is running multipathing software. There are two zones. SLM is configured so that all nodes are considered as reporting nodes.

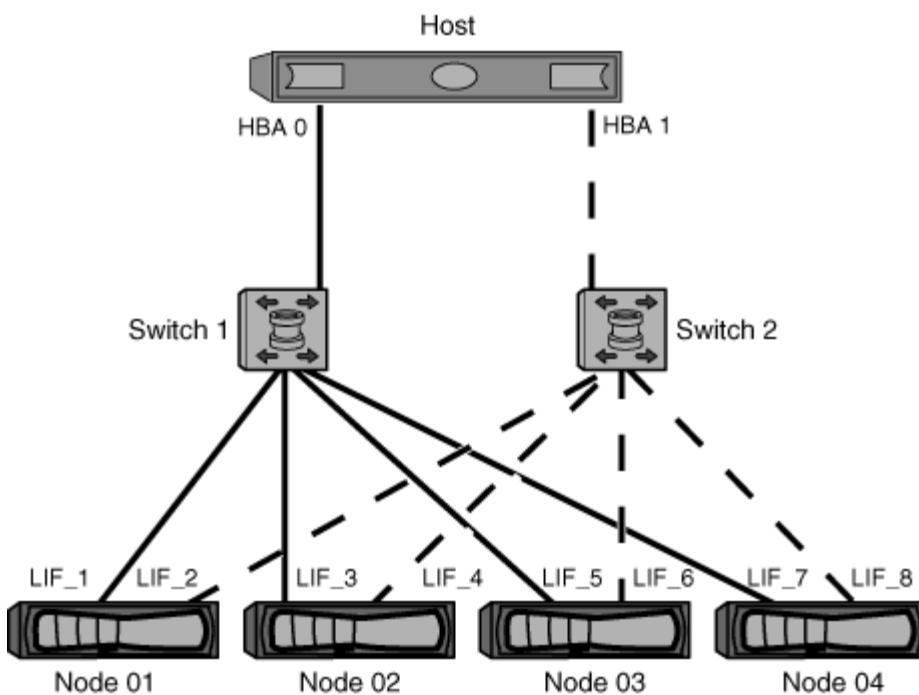

The naming convention used in this figure is just a recommendation of one possible naming convention that you can choose to use for your ONTAP solution.

- Zone 1: HBA 0, LIF_1, LIF_3, LIF_5, and LIF_7
- Zone 2: HBA 1, LIF_2, LIF_4, LIF_6, and LIF_8

Each host initiator is zoned through a different switch. Zone 1 is accessed through Switch 1. Zone 2 is accessed through Switch 2.

Each initiator can access a LIF on every node. This enables the host to still access its LUNs if a node fails. SVMs have access to all iSCSI and FC LIFs on every node in a clustered solution based on the setting for Selective LUN Map (SLM) and the reporting node configuration. You can use SLM, portsets, or FC switch zoning to reduce the number of paths from an SVM to the host and the number of paths from an SVM to a LUN.

If the configuration included more nodes, the LIFs for the additional nodes would be included in these zones.

The host operating system and multipathing software have to support the number of paths that is being used to access the LUNs on the nodes.

[NetApp Hardware Universe](#)

= Zoning restrictions for Cisco FC and FCoE switches

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

When using Cisco FC and FCoE switches, a single fabric zone must not contain more than one target LIF for the same physical port. If multiple LIFs on the same port

are in the same zone, then the LIF ports might fail to recover from a connection loss.

Regular FC switches are used for the FC-NVMe protocol in the exact same way they are used for the FC protocol.

- Multiple LIFs for the FC and FCoE protocols, can share physical ports on a node as long as they are in different zones.
- FC-NVMe and FCoE cannot share the same physical port.
- FC and FC-NVMe can share the same 32 Gb physical port.
- Cisco FC and FCoE switches require each LIF on a given port to be in a separate zone from the other LIFs on that port.
- A single zone can have both FC and FCoE LIFs. A zone can contain a LIF from every target port in the cluster, but be careful to not exceed the host's path limits and verify the SLM configuration.
- LIFs on different physical ports can be in the same zone.
- Cisco switches require that LIFs be separated.

Though not required, separating LIFs is recommended for all switches

= Requirements for shared SAN configurations

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

Shared SAN configurations are defined as hosts that are attached to both ONTAP storage systems and other vendors' storage systems. Accessing ONTAP storage systems and other vendors' storage systems from a single host is supported as long as several requirements are met.

For all of the host operating systems, it is a best practice to use separate adapters to connect to each vendor's storage systems. Using separate adapters reduces the chances of conflicting drivers and settings. For connections to an ONTAP storage system, the adapter model, BIOS, firmware, and driver must be listed as supported in the NetApp Interoperability Matrix Tool.

You should set the required or recommended timeout values and other storage parameters for the host. You must always install the NetApp software or apply the NetApp settings last.

- For AIX, you should apply the values from the AIX Host Utilities version that is listed in the Interoperability Matrix Tool for your configuration.
- For ESX, you should apply host settings by using Virtual Storage Console for VMware vSphere.
- For HP-UX, you should use the HP-UX default storage settings.
- For Linux, you should apply the values from the Linux Host Utilities version that is listed in the Interoperability Matrix Tool for your configuration.
- For Solaris, you should apply the values from the Solaris Host Utilities version that is listed in the Interoperability Matrix Tool for your configuration.
- For Windows, you should install the Windows Host Utilities version that is listed in the Interoperability Matrix Tool for your configuration.

[NetApp Interoperability Matrix Tool](#)

= Host support for multipathing

= Host support for multipathing overview

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ONTAP always uses Asymmetric Logical Unit Access (ALUA) for both FC and iSCSI paths. Be sure to use host configurations that support ALUA for FC and iSCSI protocols.

Beginning with ONTAP 9.5 multipath HA pair failover/giveback is supported for NVMe configurations using Asynchronous Namespace Access (ANA). In ONTAP 9.4, NVMe only supports one path from host to target. The application host needs to manage path failover to its high availability (HA) partner.

For information about which specific host configurations support ALUA or ANA, see the [NetApp Interoperability Matrix Tool](#) and [ONTAP SAN Host Configuration](#) for your host operating system.

= When host multipathing software is required

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If there is more than one path from the storage virtual machine (SVM) logical interfaces (LIFs) to the fabric, multipathing software is required. Multipathing software is required on the host any time the host can access a LUN through more than one path.

The multipathing software presents a single disk to the operating system for all paths to a LUN. Without multipathing software, the operating system could treat each path as a separate disk, which can lead to data corruption.

Your solution is considered to have multiple paths if you have any of the following:

- A single initiator port in the host attaching to multiple SAN LIFs in the SVM
- Multiple initiator ports attaching to a single SAN LIF in the SVM
- Multiple initiator ports attaching to multiple SAN LIFs in the SVM

In single-fabric single-node configurations, multipathing software is not required if you only have a single path from the host to the node.

Multipathing software is recommended in HA configurations. In addition to Selective LUN Map, using FC switch zoning or portsets to limit the paths used to access LUNs is recommended.

Multipathing software is also known as MPIO (multipath I/O) software.

= Recommended number of paths from host to nodes in cluster

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You should not exceed more than eight paths from your host to each node in your cluster, paying attention to the total number of paths that can be supported for the host OS and the multipathing used on the host.

You should have a minimum of two paths per LUN connecting to each reporting node through Selective LUN Map (SLM) being used by the storage virtual machine (SVM) in your cluster. This eliminates single points of failure and enables the system to survive component failures.

If you have four or more nodes in your cluster or more than four target ports being used by the SVMs in any of your nodes, you can use the following methods to limit the number of paths that can be used to access LUNs on your nodes so that you do not exceed the recommended maximum of eight paths.

- SLM

SLM reduces the number of paths from the host to LUN to only paths on the node owning the LUN and the owning node's HA partner. SLM is enabled by default.

- Portsets for iSCSI
- FC igroup mappings from your host
- FC switch zoning

= Configuration limits

= Determine the number of supported nodes for SAN configurations

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The number of nodes per cluster supported by ONTAP varies depending on your version of ONTAP, the storage controller models in your cluster, and the protocol of your cluster nodes.

About this task

If any node in the cluster is configured for FC, FC-NVMe, FCoE, or iSCSI, that cluster is limited to the SAN node limits. Node limits based on the controllers in your cluster are listed in the *Hardware Universe*.

Steps

1. Go to [NetApp Hardware Universe](#).
2. Click **Platforms** in the upper left (next to the **Home** button) and select the platform type.
3. Select the check box next to your version of ONTAP.

A new column is displayed for you to choose your platforms.

4. Select the check boxes next to the platforms used in your solution.
5. Unselect the **Select All** check box in the **Choose Your Specifications** column.
6. Select the **Max Nodes per Cluster (NAS/SAN)** check box.
7. Click **Show Results**.

Related information

[NetApp Hardware Universe](#)

= Determine the number of supported hosts per cluster in FC and FC-NVMe configurations

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The maximum number of SAN hosts that can be connected to a cluster varies greatly based upon your specific combination of multiple cluster attributes, such as the number of hosts connected to each cluster node, initiators per host, sessions per host, and nodes in the cluster.

About this task

For FC and FC-NVMe configurations, you should use the number of initiator-target nexuses (ITNs) in your system to determine whether you can add more hosts to your cluster.

An ITN represents one path from the host's initiator to the storage system's target. The maximum number of ITNs per node in FC and FC-NVMe configurations is 2,048. As long as you are below the maximum number of ITNs, you can continue to add hosts to your cluster.

To determine the number of ITNs used in your cluster, perform the following steps for each node in the cluster.

Steps

1. Identify all the LIFs on a given node.
2. Run the following command for every LIF on the node:

```
fcp initiator show -fields wwpn, lif
```

The number of entries displayed at the bottom of the command output represents your number of ITNs for that LIF.

3. Record the number of ITNs displayed for each LIF.
4. Add the number of ITNs for each LIF on every node in your cluster.

This total represents the number of ITNs in your cluster.

= Determine the supported number of hosts in iSCSI configurations

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The maximum number of SAN hosts that can be connected in iSCSI configurations varies greatly based on your specific combination of multiple cluster attributes, such as the number of hosts connected to each cluster node, initiators per host, logins per host, and nodes in the cluster.

About this task

The number of hosts that can be directly connected to a node or that can be connected through one or more switches depends on the number of available Ethernet ports. The number of available Ethernet

ports is determined by the model of the controller and the number and type of adapters installed in the controller. The number of supported Ethernet ports for controllers and adapters is available in the *Hardware Universe*.

For all multi-node cluster configurations, you must determine the number of iSCSI sessions per node to know whether you can add more hosts to your cluster. As long as your cluster is below the maximum number of iSCSI sessions per node, you can continue to add hosts to your cluster. The maximum number of iSCSI sessions per node varies based on the types of controllers in your cluster.

Steps

1. Identify all of the target portal groups on the node.
2. Check the number of iSCSI sessions for every target portal group on the node:

```
iscsi session show -tpgroup tpgroup
```

The number of entries displayed at the bottom of the command output represents your number of iSCSI sessions for that target portal group.

3. Record the number of iSCSI sessions displayed for each target portal group.
4. Add the number of iSCSI sessions for each target portal group on the node.

The total represents the number of iSCSI sessions on your node.

= FC switch configuration limits

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Fibre Channel switches have maximum configuration limits, including the number of logins supported per port, port group, blade, and switch. The switch vendors document their supported limits.

Each FC logical interface (LIF) logs into an FC switch port. The total number of logins from a single target on the node equals the number of LIFs plus one login for the underlying physical port. Do not exceed the switch vendor's configuration limits for logins or other configuration values. This also holds true for the initiators being used on the host side in virtualized environments with NPIV enabled. Do not exceed the switch vendor's configuration limits for logins for either the target or the initiators being used in the solution.

== Brocade switch limits

You can find the configuration limits for Brocade switches in the *Brocade Scalability Guidelines*.

== Cisco Systems switch limits

You can find the configuration limits for Cisco switches in the [Cisco Configuration Limits](#) guide for your version of Cisco switch software.

= Calculate queue depth overview

:icons: font

:relative_path: ./san-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You might need to tune your FC queue depth on the host to achieve the maximum values for ITNs per node and FC port fan-in. The maximum number of LUNs and the number of HBAs that can connect to an FC port are limited by the available queue depth on the FC target ports.

About this task

Queue depth is the number of I/O requests (SCSI commands) that can be queued at one time on a storage controller. Each I/O request from the host's initiator HBA to the storage controller's target adapter consumes a queue entry. Typically, a higher queue depth equates to better performance. However, if the storage controller's maximum queue depth is reached, that storage controller rejects incoming commands by returning a QFULL response to them. If a large number of hosts are accessing a storage controller, you should plan carefully to avoid QFULL conditions, which significantly degrade system performance and can lead to errors on some systems.

In a configuration with multiple initiators (hosts), all hosts should have similar queue depths. Because of the inequality in queue depth between hosts connected to the storage controller through the same target port, hosts with smaller queue depths are being deprived of access to resources by hosts with larger queue depths.

The following general recommendations can be made about "tuning" queue depths:

- For small to mid-size systems, use an HBA queue depth of 32.
- For large systems, use an HBA queue depth of 128.
- For exception cases or performance testing, use a queue depth of 256 to avoid possible queuing problems.
- All hosts should have the queue depths set to similar values to give equal access to all hosts.
- To avoid performance penalties or errors, the storage controller target FC port queue depth must not be exceeded.

Steps

1. Count the total number of FC initiators in all of the hosts that connect to one FC target port.
2. Multiply by 128.
 - If the result is less than 2,048, set the queue depth for all initiators to 128.
You have 15 hosts with one initiator connected to each of two target ports on the storage controller. $15 \times 128 = 1,920$. Because 1,920 is less than the total queue depth limit of 2,048, you can set the queue depth for all of your initiators to 128.
 - If the result is greater than 2,048, go to step 3.
You have 30 hosts with one initiator connected to each of two target ports on the storage controller. $30 \times 128 = 3,840$. Because 3,840 is greater than the total queue depth limit of 2,048, you should choose one of the options under step 3 for remediation.
3. Choose one of the following options to add more hosts to the storage controller.
 - Option 1:
 - i. Add more FC target ports.
 - ii. Redistribute your FC initiators.
 - iii. Repeat steps 1 and 2.

The desired queue depth of 3,840 exceeds the available queue depth per port. To remedy this, you can add a two-port FC target adapter to each controller, then rezone your FC

switches so that 15 of your 30 hosts connect to one set of ports, and the remaining 15 hosts connect to a second set of ports. The queue depth per port is then reduced to $15 \times 128 = 1,920$.

- Option 2:
 - i. Designate each host as “large” or “small” based on its expected I/O need.
 - ii. Multiply the number of large initiators by 128.
 - iii. Multiply the number of small initiators by 32.
 - iv. Add the two results together.
 - v. If the result is less than 2,048, set the queue depth for large hosts to 128 and the queue depth for small hosts to 32.
 - vi. If the result is still greater than 2,048 per port, reduce the queue depth per initiator until the total queue depth is less than or equal to 2,048.

To estimate the queue depth needed to achieve a certain I/O per second throughput, use this formula:

Needed queue depth = (Number of I/O per second) × (Response time)

For example, if you need 40,000 I/O per second with a response time of 3 milliseconds, the needed queue depth = $40,000 \times (.003) = 120$.

The maximum number of hosts that you can connect to a target port is 64, if you decide to limit the queue depth to the basic recommendation of 32. However, if you decide to have a queue depth of 128, then you can have a maximum of 16 hosts connected to one target port. The larger the queue depth, the fewer hosts that a single target port can support. If your requirement is such that you cannot compromise on the queue depth, then you should get more target ports.

The desired queue depth of 3,840 exceeds the available queue depth per port. You have 10 “large” hosts that have high storage I/O needs, and 20 “small” hosts that have low I/O needs. Set the initiator queue depth on the large hosts to 128 and the initiator queue depth on the small hosts to 32.

Your resulting total queue depth is $(10 \times 128) + (20 \times 32) = 1,920$.

You can spread the available queue depth equally across each initiator.

Your resulting queue depth per initiator is $2,048 \div 30 = 68$.

= Set queue depths on SAN hosts

:icons: font

:relative_path: ./san-config

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

You might need to change the queue depths on your host to achieve the maximum values for ITNs per node and FC port fan-in.

== AIX hosts

You can change the queue depth on AIX hosts using the chdev command. Changes made using the chdev command persist across reboots.

Examples:

- To change the queue depth for the hdisk7 device, use the following command:

```
chdev -l hdisk7 -a queue_depth=32
```

- To change the queue depth for the fcs0 HBA, use the following command:

```
chdev -l fcs0 -a num_cmd_elems=128
```

The default value for `num_cmd_elems` is 200. The maximum value is 2,048.

It might be necessary to take the HBA offline to change `num_cmd_elems` and then bring it back online using the `rmdev -l fcs0 -R` and `makdev -l fcs0 -P` commands.

== HP-UX hosts

You can change the LUN or device queue depth on HP-UX hosts using the kernel parameter `scsi_max_qdepth`. You can change the HBA queue depth using the kernel parameter `max_fcp_reqs`.

- The default value for `scsi_max_qdepth` is 8. The maximum value is 255.

`scsi_max_qdepth` can be dynamically changed on a running system using the `-u` option on the `kmtune` command. The change will be effective for all devices on the system. For example, use the following command to increase the LUN queue depth to 64:

```
kmtune -u -s scsi_max_qdepth=64
```

It is possible to change queue depth for individual device files using the `scsictl` command. Changes using the `scsictl` command are not persistent across system reboots. To view and change the queue depth for a particular device file, execute the following command:

```
scsictl -a /dev/rdsk/c2t2d0
```

```
scsictl -m queue_depth=16 /dev/rdsk/c2t2d0
```

- The default value for `max_fcp_reqs` is 512. The maximum value is 1024.

The kernel must be rebuilt and the system must be rebooted for changes to `max_fcp_reqs` to take effect. To change the HBA queue depth to 256, for example, use the following command:

```
kmtune -u -s max_fcp_reqs=256
```

== Solaris hosts

You can set the LUN and HBA queue depth for your Solaris hosts.

- For LUN queue depth: The number of LUNs in use on a host multiplied by the per-LUN throttle (`lun-queue-depth`) must be less than or equal to the `tgt-queue-depth` value on the host.
- For queue depth in a Sun stack: The native drivers do not allow for per LUN or per target `max_throttle` settings at the HBA level. The recommended method for setting the `max_throttle`

value for native drivers is on a per-device type (VID_PID) level in the /kernel/drv/sd.conf and /kernel/drv/ssd.conf files. The host utility sets this value to 64 for MPxIO configurations and 8 for Veritas DMP configurations.

Steps

1. # cd/kernel/drv
2. # vi lpfc.conf
3. Search for /tgt-queue (/tgt-queue)
tgt-queue-depth=32

The default value is set to 32 at installation.

4. Set the desired value based on the configuration of your environment.
5. Save the file.
6. Reboot the host using the sync; sync; sync; reboot -- -r command.

== VMware hosts for a QLogic HBA

Use the esxcfg-module command to change the HBA timeout settings. Manually updating the esx.conf file is not recommended.

Steps

1. Log on to the service console as the root user.
2. Use the #vmkload_mod -l command to verify which Qlogic HBA module is currently loaded.
3. For a single instance of a Qlogic HBA, run the following command:

```
#esxcfg-module -s ql2xmaxqdepth=64 qla2300_707
```

This example uses qla2300_707 module. Use the appropriate module based on the output of vmkload_mod -l.

4. Save your changes using the following command:

```
#/usr/sbin/esxcfg-boot -b
```

5. Reboot the server using the following command:

```
#reboot
```

6. Confirm the changes using the following commands:

- a. #esxcfg-module -g qla2300_707
- b. qla2300_707 enabled = 1 options = 'ql2xmaxqdepth=64'

== VMware hosts for an Emulex HBA

Use the esxcfg-module command to change the HBA timeout settings. Manually updating the esx.conf file is not recommended.

Steps

1. Log on to the service console as the root user.
2. Use the `#vmkload_mod -l grep lpfc` command to verify which Emulex HBA is currently loaded.
3. For a single instance of an Emulex HBA, enter the following command:

```
#esxcfg-module -s lpfc0_lun_queue_depth=16 lpfcdd_7xx
```

Depending on the model of the HBA, the module can be either `lpfcdd_7xx` or `lpfcdd_732`. The above command uses the `lpfcdd_7xx` module. You should use the appropriate module based on the outcome of `vmkload_mod -l`.

Running this command will set the LUN queue depth to 16 for the HBA represented by `lpfc0`.

4. For multiple instances of an Emulex HBA, run the following command:

```
a esxcfg-module -s "lpfc0_lun_queue_depth=16 lpfc1_lun_queue_depth=16"  
lpfcdd_7xx
```

The LUN queue depth for `lpfc0` and the LUN queue depth for `lpfc1` is set to 16.

5. Enter the following command:

```
#esxcfg-boot -b
```

6. Reboot using `#reboot`.

== Windows hosts for an Emulex HBA

On Windows hosts, you can use the `LPUTILNT` utility to update the queue depth for Emulex HBAs.

Steps

1. Run the `LPUTILNT` utility located in the `C:\WINNT\system32` directory.
2. Select **Drive Parameters** from the menu on the right side.
3. Scroll down and double-click **QueueDepth**.

If you are setting **QueueDepth** greater than 150, the following Windows Registry value also need to be increased appropriately:

`HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\lpxnds\Parameters\Device\NumberOfRequests`

== Windows hosts for a Qlogic HBA

On Windows hosts, you can use the `and the SANsurfer` HBA manager utility to update the queue depths for Qlogic HBAs.

Steps

1. Run the `SANsurfer` HBA manager utility.
2. Click on **HBA port > Settings**.

3. Click **Advanced HBA port settings** in the list box.

4. Update the Execution Throttle parameter.

== Linux hosts for Emulex HBA

You can update the queue depths of an Emulex HBA on a Linux host. To make the updates persistent across reboots, you must then create a new RAM disk image and reboot the host.

Steps

1. Identify the queue depth parameters to be modified:

```
modinfo lpfc|grep queue_depth
```

The list of queue depth parameters with their description is displayed. Depending on your operating system version, you can modify one or more of the following queue depth parameters:

- lpfc_lun_queue_depth: Maximum number of FC commands that can be queued to a specific LUN (uint)
- lpfc_hba_queue_depth: Maximum number of FC commands that can be queued to an lpfc HBA (uint)
- lpfc_tgt_queue_depth: Maximum number of FC commands that can be queued to a specific target port (uint)

The lpfc_tgt_queue_depth parameter is applicable only for Red Hat Enterprise Linux 7.x systems, SUSE Linux Enterprise Server 11 SP4 systems and 12.x systems.

2. Update the queue depths by adding the queue depth parameters to the /etc/modprobe.conf file for a Red Hat Enterprise Linux 5.x system and to the /etc/modprobe.d/scsi.conf file for a Red Hat Enterprise Linux 6.x or 7.x system, or a SUSE Linux Enterprise Server 11.x or 12.x system.

Depending on your operating system version, you can add one or more of the following commands:

- options lpfc lpfc_hba_queue_depth=new_queue_depth
- options lpfc lpfc_lun_queue_depth=new_queue_depth
- options lpfc_tgt_queue_depth=new_queue_depth

3. Create a new RAM disk image, and then reboot the host to make the updates persistent across reboots.

For more information, see the [System administration](#) for your version of Linux operating system.

4. Verify that the queue depth values are updated for each of the queue depth parameter that you have modified:

```
cat /sys/class/scsi_host/host_number/lpfc_lun_queue_depth
cat /sys/class/scsi_host/host_number/lpfc_tgt_queue_depth
cat /sys/class/scsi_host/host_number/lpfc_hba_queue_depth
```

```
root@localhost ~]#cat  
/sys/class/scsi_host/host5/lpfc_lun_queue_depth  
30
```

The current value of the queue depth is displayed.

== Linux hosts for QLogic HBA

You can update the device queue depth of a QLogic driver on a Linux host. To make the updates persistent across reboots, you must then create a new RAM disk image and reboot the host. You can use the QLogic HBA management GUI or command-line interface (CLI) to modify the QLogic HBA queue depth.

This task shows how to use the QLogic HBA CLI to modify the QLogic HBA queue depth

Steps

1. Identify the device queue depth parameter to be modified:

```
modinfo qla2xxx | grep ql2xmaxqdepth
```

You can modify only the `ql2xmaxqdepth` queue depth parameter, which denotes the maximum queue depth that can be set for each LUN. The default value is 64 for RHEL 7.5 and later. The default value is 32 for RHEL 7.4 and earlier.

```
root@localhost ~]# modinfo qla2xxx|grep ql2xmaxqdepth  
parm:      ql2xmaxqdepth:Maximum queue depth to set for each LUN.  
Default is 64. (int)
```

2. Update the device queue depth value:

- If you want to make the modifications persistent, perform the following steps:
 - i. Update the queue depths by adding the queue depth parameter to the `/etc/modprobe.conf` file for a Red Hat Enterprise Linux 5.x system and to the `/etc/modprobe.d/scsi.conf` file for a Red Hat Enterprise Linux 6.x or 7.x system, or a SUSE Linux Enterprise Server 11.x or 12.x system: `options qla2xxx ql2xmaxqdepth=new_queue_depth`
 - ii. Create a new RAM disk image, and then reboot the host to make the updates persistent across reboots.

For more information, see the [System administration](#) for your version of Linux operating system.

- If you want to modify the parameter only for the current session, run the following command:

```
echo new_queue_depth > /sys/module/qla2xxx/parameters/ql2xmaxqdepth
```

In the following example, the queue depth is set to 128.

```
echo 128 > /sys/module/qla2xxx/parameters/ql2xmaxqdepth
```

3. Verify that the queue depth values are updated:

```
cat /sys/module/qla2xxx/parameters/ql2xmaxqdepth
```

The current value of the queue depth is displayed.

4. Modify the QLogic HBA queue depth by updating the firmware parameter Execution Throttle from the QLogic HBA BIOS.

- a. Log in to the QLogic HBA management CLI:

```
/opt/QLogic_Corporation/QConvergeConsoleCLI/qaucli
```

- b. From the main menu, select the Adapter Configuration option.

```
[root@localhost ~]#  
/opt/QLogic_Corporation/QConvergeConsoleCLI/qaucli  
Using config file:  
/opt/QLogic_Corporation/QConvergeConsoleCLI/qaucli.cfg  
Installation directory:  
/opt/QLogic_Corporation/QConvergeConsoleCLI  
Working dir: /root

= Considerations for SAN configurations in a MetroCluster environment
:icons: font
:relative_path: ./san-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You must be aware of certain considerations when using SAN configurations in a MetroCluster environment.

- Two-node, four-node, and eight-node MetroCluster configurations do not support front-end FC fabric “routed” vSAN configurations.
- Two-node, four-node, and eight-node MetroCluster configurations support SAN protocols.
- When using SAN client configurations, you must check whether any special considerations for MetroCluster configurations are included in the notes that are provided in the Interoperability Matrix Tool (IMT).
- The MetroCluster is using the same WWPNs on both sides of the front-end SAN.

To avoid overlap when the old port goes offline and the new port comes online, use the following steps to configure the front-end switches:

For a...	Use these steps:

Cisco switch

1. Connect to the switch and log in.

2. Enter configuration mode:

```
switch# config t  
switch(config) #
```

3. Overwrite the first device entry in the name server database with the new device:

```
switch(config)# no fcns reject-duplicate-pwwn vsan  
1
```

4. In switches that are running NX-OS 8.x, confirm that the flogi quiesce timeout is set to zero:

a. Display the quiesce timerval:

```
switch(config)# show flogi interval info | i quiesce
```

```
Stats: fs flogi quiesce timerval: 0
```

b. If the output in the previous step does not indicate that the timerval is zero, then set it to zero:

```
switch(config)# flogi scale enable
```

```
switch(config)$ flogi quiesce timeout 0
```

Brocade switch

1. Connect to the switch and log in.
2. Enter the `switchDisable` command.
3. Enter the `configure` command, and press **y** at the prompt.

```
F-Port login parameters (yes, y, no, n): [no] y
```

4. Choose setting 1:

```
- 0: First login take precedence over the second  
login (default)  
- 1: Second login overrides first login.  
- 2: the port type determines the behavior  
Enforce FLOGI/FDISC login: (0..2) [0] 1
```

5. Respond to the remaining prompts, or press **Ctrl + D**.
6. Enter the `switchEnable` command.

For further MetroCluster-specific host information, refer to the following NetApp Knowledgebase articles:

[What are AIX Host support considerations in a MetroCluster configuration?](#)

[Solaris host support considerations in a MetroCluster configuration](#)

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/

= S3 configuration with System Manager

= ONTAP S3 configuration overview with System Manager

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/

The topics in this section show you how to configure and manage S3 object storage services with System Manager in ONTAP 9.8 and later releases.

Beginning with ONTAP 9.8, you can enable an ONTAP Simple Storage Service (S3) object storage server in an ONTAP cluster. For more information, see [S3 support in ONTAP 9](#).

System Manager supports two on-premises use case scenarios for serving S3 object storage:

- FabricPool tier to a bucket on local cluster (tier to a local bucket) or remote cluster (cloud tier).
- S3 client app access to a bucket on the local cluster or a remote cluster.

For more information about FabricPool tiering, see [FabricPool tier management overview with System Manager](#).

ONTAP S3 is appropriate if you want S3 capabilities on existing clusters without additional hardware and management. For deployments larger than 300TB, NetApp StorageGRID software continues to be the NetApp flagship solution for object storage. For more information, see the [StorageGRID documentation](#).

When you create an S3 bucket using System Manager, ONTAP configures a default performance service level that is the highest available on your system. For example, on an AFF system, the default setting would be **Extreme**. Performance service levels are predefined adaptive Quality of Service (QoS) policy groups. Instead of one of the default service levels, you can specify a custom QoS policy group or no policy group.

Predefined adaptive QoS policy groups are:

- **Extreme**: Used for applications that expect the lowest latency and highest performance.
- **Performance**: Used for applications with modest performance needs and latency.
- **Value**: Used for applications for which throughput and capacity are more important than latency.
- **Custom**: Specify a custom QoS policy or no QoS policy.

If you select **Use for tiering**, no performance service levels are selected, and the system tries to select low-cost media with optimal performance for the tiered data.

See also: [Use adaptive QoS policy groups](#).

ONTAP tries to provision this bucket on local tiers that have the most appropriate disks, satisfying the chosen service level. However, if you need to specify which disks to include in the bucket, consider configuring S3 object storage from the CLI by specifying the local tiers (aggregate). If you configure the S3 server from the CLI, you can still manage it with System Manager if desired. For more information, see the documentation for [S3 configuration with the CLI](#).

= Enable an S3 server on a storage

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/

Add an S3 server to a new or existing storage VM for serving content to S3 clients.

An S3 server can coexist in a storage VM with other protocol servers, or you can create a new storage VM to isolate the namespace and workload.

Before you begin

You should be prepared to enter an S3 server name (FQDN) and IP addresses for interface role Data.

If you are using an external-CA signed certificate, you will be prompted to enter it during this procedure; you also have the option to use a system-generated certificate.

Steps

1. Enable S3 on a storage VM.

- a. Add a new storage VM: click **Storage > Storage VMs**, then click **Add**.

If this is a new system with no existing storage VMs: click **Dashboard > Configure Protocols**.

If you are adding an S3 server to an existing storage VM: click **Storage > Storage VMs**, select a storage VM, click **Settings**, and then click  under **S3**.

- b. Click **Enable S3**, then enter the S3 Server Name.

This will be the Fully Qualified Domain Name (FQDN) that clients will use.

- c. Select the certificate type.

Whether you select system-generated certificate or one of your own, it will be required for client access.

- d. Enter the network interfaces.

2. If you selected the system-generated certificate, you see the certificate information when the new storage VM creation is confirmed. Click **Download** and save it for client access.

- The secret key will not be displayed again.
- If you need the certificate information again: click **Storage > Storage VMs**, select the storage VM, and click **Settings**.

= Provision buckets

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/

Add an S3 bucket for the new S3 object store or add additional buckets to an existing object store.

For remote client access, you must configure buckets in an S3-enabled storage VM. If you create a bucket in a storage VM that is not S3-enabled, it will only be available for local tiering.

Beginning with ONTAP 9.8, when you provision storage, QoS is enabled by default. You can disable QoS or choose a custom QoS policy during the provisioning process or at a later time.

Steps

1. Add a new bucket on an S3-enabled storage VM.
 - a. Click **Storage > Buckets**, then click **Add**.
 - b. Enter a name, select the storage VM, and enter a size.
 - If you click **Save** at this point, a bucket is created with these default settings:
 - No users are granted access to the bucket unless any group policies are already in effect.
-  You should not use the S3 root user to manage ONTAP object storage and share its permissions, because it has unlimited access to the object store. Instead, create a user or group with administrative privileges that you assign.
- A Quality of Service (performance) level that is the highest available for your system.
 - You can click **More Options** to configure user permissions and performance level when you configure the bucket, or you can modify these settings later.
 - You must have already created user and groups before using **More Options** to configure their permissions.
 - If you intend to use the S3 object store for FabricPool tiering, consider selecting **Use for tiering** (use low-cost media with optimal performance for the tiered data) rather than a performance service level.

2. On S3 client apps – another ONTAP system or an external 3rd-party app – verify access to the new bucket by entering the following:
 - The S3 server CA certificate.
 - The user's access key and secret key.
 - The S3 server FQDN name and bucket name.

= Add S3 users and groups

```
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ../
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/
```

Edit the storage VM to add users, and to add users to groups.

Steps

1. Edit the storage VM: click **Storage > storage VMs**, click the storage VM, click **Settings** and then click  under S3.
2. Add a user: click **Users**, then click **Add**.
 - a. Enter a name and click **Save**.
 - b. Be sure to save the access key and secret key, they will be required for access from S3 clients.
3. If desired, add a group: click **Groups**, then click **Add**.
 - a. Enter a group name and select from a list of users.
 - b. You can select an existing group policy or add one now, or you can add a policy later.

= Manage user access to buckets
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/

Edit the bucket to modify the list users with access to the bucket and specify their permissions.

User and group permissions can be granted when the bucket is created or as needed later. You can also modify the bucket capacity and QoS policy group assignment.

You must have already created users or groups before granting permissions.

In ONTAP 9.9.1 and later releases, if you plan to support AWS client object tagging functionality with the ONTAP S3 server, the actions `GetObjectTagging`, `PutObjectTagging`, and `DeleteObjectTagging` need to be allowed using the bucket or group policies.

Steps

1. Edit the bucket: click **Storage > Buckets**, click the desired bucket, and then click **Edit**.

When adding or modifying permissions, you can specify the following parameters:

- Principal: the user or group to whom access is granted.
- Effect: allows or denies access to a user or group.
- Actions: permissible actions in the bucket for a given user or group.
- Resources: paths and names of objects within the bucket for which access is granted or denied.

The defaults **bucketname** and **bucketname/*** grant access to all objects in the bucket. You can also grant access to single objects; for example, **bucketname/*_readme.txt**.

- Conditions (optional): expressions that are evaluated when access is attempted. For example, you can specify a list of IP addresses for which access will be allowed or denied.

= Manage user access to S3-enabled storage VMs

:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/

Edit the storage VM to add a policy that controls user and group access permissions to multiple buckets.

You can add a group policy to manage access to one or more buckets in an S3-enabled storage VM, rather than managing access permissions for individual buckets. Doing so simplifies management when buckets are added or when access needs change.

You must have already created users and at least one group before granting permissions in a policy.

In ONTAP 9.9.1 and later releases, if you plan to support AWS client object tagging functionality with the ONTAP S3 server, the actions `GetObjectTagging`, `PutObjectTagging`, and `DeleteObjectTagging` need to be allowed using the bucket or group policies.

Steps

1. Edit the storage VM: click **Storage > storage VMs**, click the storage VM, click **Settings** and then click  under S3.
2. Add a user: click **Policies**, then click **Add**.
 - a. Enter a policy name and select from a list of groups.
 - b. Select an existing default policy or add a new one.

When adding or modifying a group policy, you can specify the following parameters:

- Group: the groups to whom access is granted.
- Effect: allows or denies access to one or more groups.
- Actions: permissible actions in one or more buckets for a given group.
- Resources: paths and names of objects within one or more buckets for which access is granted or denied.

For example:

- * grants access to all buckets in the storage VM.
- **bucketname** and **bucketname/*** grant access to all objects in a specific bucket.
- **bucketname/readme.txt** grants access to an object in a specific bucket.

- c. If desired, add statements to existing policies.

= S3 configuration with the CLI

= S3 configuration overview with the CLI

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

You can use ONTAP 9 CLI commands to configure S3 client access to objects contained in a bucket in an SVM. The procedures include examples and advanced configuration options.

You should use these procedures if you want to configure S3 object storage in the following way:

- You want to provide S3 object storage from an existing cluster running ONTAP.

ONTAP deployment is appropriate if you want S3 capabilities on existing clusters without additional hardware and management. For deployments larger than 300TB, NetApp StorageGRID software continues to be the NetApp flagship solution for object storage.

- You want to use the command-line interface (CLI), not System Manager or an automated scripting tool.

If you want the ability to specify which aggregates are used for buckets, you can only do so using the CLI.

- You want to use best practices, not explore every available option.

Details about command syntax are available from CLI help and ONTAP man pages.

Additional information about ONTAP technology and interaction with external services is available in the ONTAP Reference Library and in Technical Reports (TRs).

- You have cluster administrator privileges, not SVM administrator privileges.

= S3 support in ONTAP 9

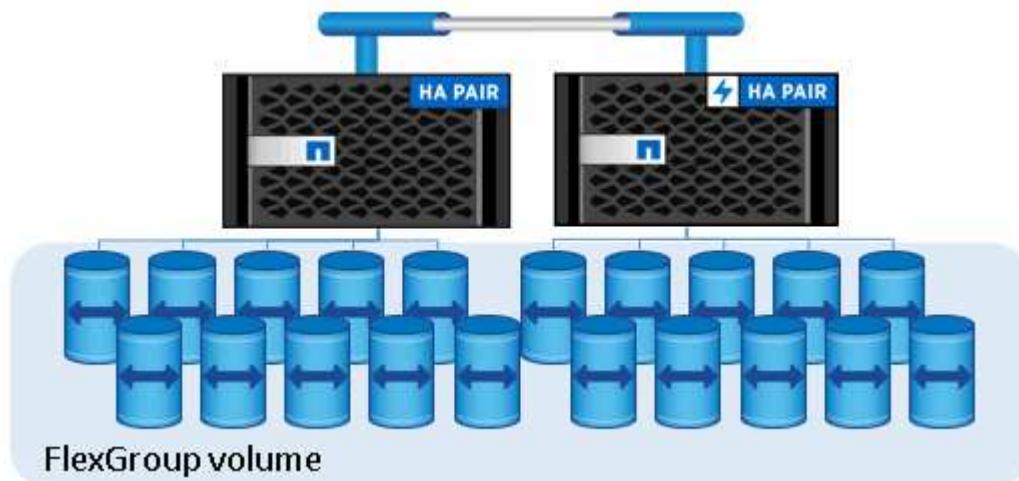

= ONTAP S3 architecture and use cases

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

In ONTAP, the underlying architecture for a bucket is a FlexGroup volume—a single namespace that is made up of multiple constituent member volumes but is managed as a single volume.

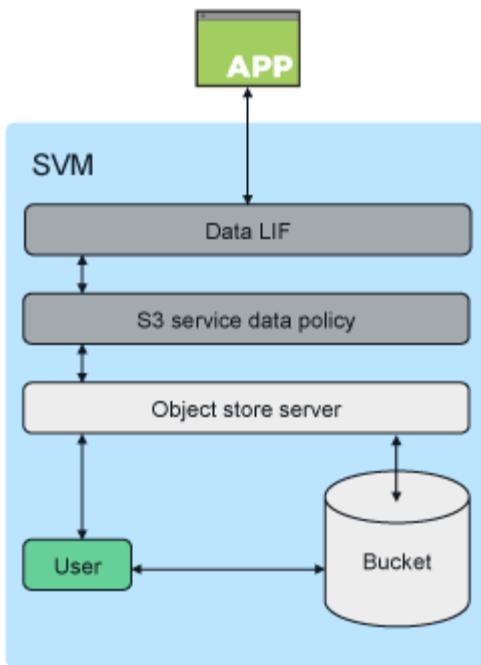

Buckets are only limited by the physical maximums of the underlying hardware, architectural maximums could be higher. Buckets can take advantage of FlexGroup elastic sizing to automatically grow a constituent of a FlexGroup volume if it is running out of space. There is a limit of 1000 buckets per FlexGroup volume, or 1/3 of the FlexGroup volume's capacity (to account for data growth in buckets).

No NAS or SAN protocol access is permitted to the FlexGroup volume that contain S3 buckets.

Access to the bucket is provided through authorized users and client applications.

There are three primary use cases for client access to ONTAP S3 services:

- For ONTAP systems using ONTAP S3 as a remote FabricPool capacity (cloud) tier

The S3 server and bucket containing the capacity tier (for *cold* data) is on a different cluster than the performance tier (for *hot* data).

- For ONTAP systems using ONTAP S3 as a local FabricPool tier

The S3 server and bucket containing the capacity tier is on the same cluster, but on a different HA pair, as the performance tier.

- For external S3 client apps

ONTAP S3 serves S3 client apps run on non-NetApp systems.

It is a best practice to provide access to ONTAP S3 buckets using HTTPS. When HTTPS is enabled, security certificates are required for proper integration with SSL/TLS. Client users' access and secret keys are then required to authenticate the user with ONTAP S3 as well as authorizing the users' access permissions for operations within ONTAP S3. The client application should also have access to the root CA certificate (the ONTAP S3 server's signed certificate) to be able to authenticate the server and create a secure connection between client and server.

Users are created within the S3-enabled SVM, and their access permissions can be controlled at the bucket or SVM level; that is, they can be granted access to one or more buckets within the SVM.

HTTPS is enabled by default on ONTAP S3 servers. It is possible to disable HTTPS and enable HTTP for client access, in which case authentication using CA certificates is not required. However, when HTTP is enabled and HTTPS is disabled, all communication with the ONTAP S3 server are sent over the network in clear text.

For additional information, see [Technical Report: S3 in ONTAP Best Practices](#)

FlexGroup volumes management

= ONTAP version support for S3 object storage
:icons: font
:relative_path: ./s3-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

In ONTAP 9.7, S3 object storage was introduced as a public preview. That version was not intended for production environments and will no longer be updated as of ONTAP 9.8. Only ONTAP 9.8 and later releases support S3 object storage in production environments.

S3 buckets created with the 9.7 public preview can be used in ONTAP 9.8 and later, but cannot take advantage of feature enhancements. If you have buckets created with the 9.7 public preview, you should migrate the contents of those buckets to 9.8 buckets for feature support, security, and performance enhancements.

In ONTAP 9.9.1 and later releases, ONTAP S3 is supported with Cloud Volumes ONTAP for Azure, but not for AWS or Google Cloud.

= ONTAP S3 supported actions
:icons: font
:relative_path: ./s3-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

== Bucket operations

Actions marked with an asterisk are supported by ONTAP, not S3 REST APIs

- DeleteBucket*
- DeleteBucketPolicy*
- GetBucketAcl
- HeadBucket
- ListBuckets
- PutBucket*

== Object operations

Beginning with ONTAP 9.9.1, ONTAP S3 supports object metadata and tagging.

- PutObject and CreateMultipartUpload now include key-value pairs using x-amz-meta-<key>. For example: x-amz-meta-project: ontap_s3.
- GetObject. and HeadObject now return user-defined metadata.
- Unlike metadata, tags can be read independently of objects using:
 - PutObjectTagging
 - GetObjectTagging
 - DeleteObjectTagging

Supported object actions:

- PutObject
- PutObjectTagging (beginning with ONTAP 9.9.1)
- GetObject
- GetObjectAcl
- GetObjectTagging (beginning with ONTAP 9.9.1)
- DeleteObject
- DeleteObjectTagging (beginning with ONTAP 9.9.1)
- HeadObject
- ListObjects
- ListObjectsV2
- ListParts
- UploadPart
- AbortMultipartUpload
- CompleteMultipartUpload
- CreateMultipartUpload
- ListMultipartUpload

== Group policies

These operations are not specific to S3 and are generally associated with Identity and Management (IAM) processes. ONTAP supports these commands but does not use the IAM REST APIs.

- Create Policy
- AttachGroup Policy

== User management

These operations are not specific to S3 and are generally associated with IAM processes.

- CreateUser
- DeleteUser
- CreateGroup
- DeleteGroup

= ONTAP S3 interoperability

= About the S3 configuration process

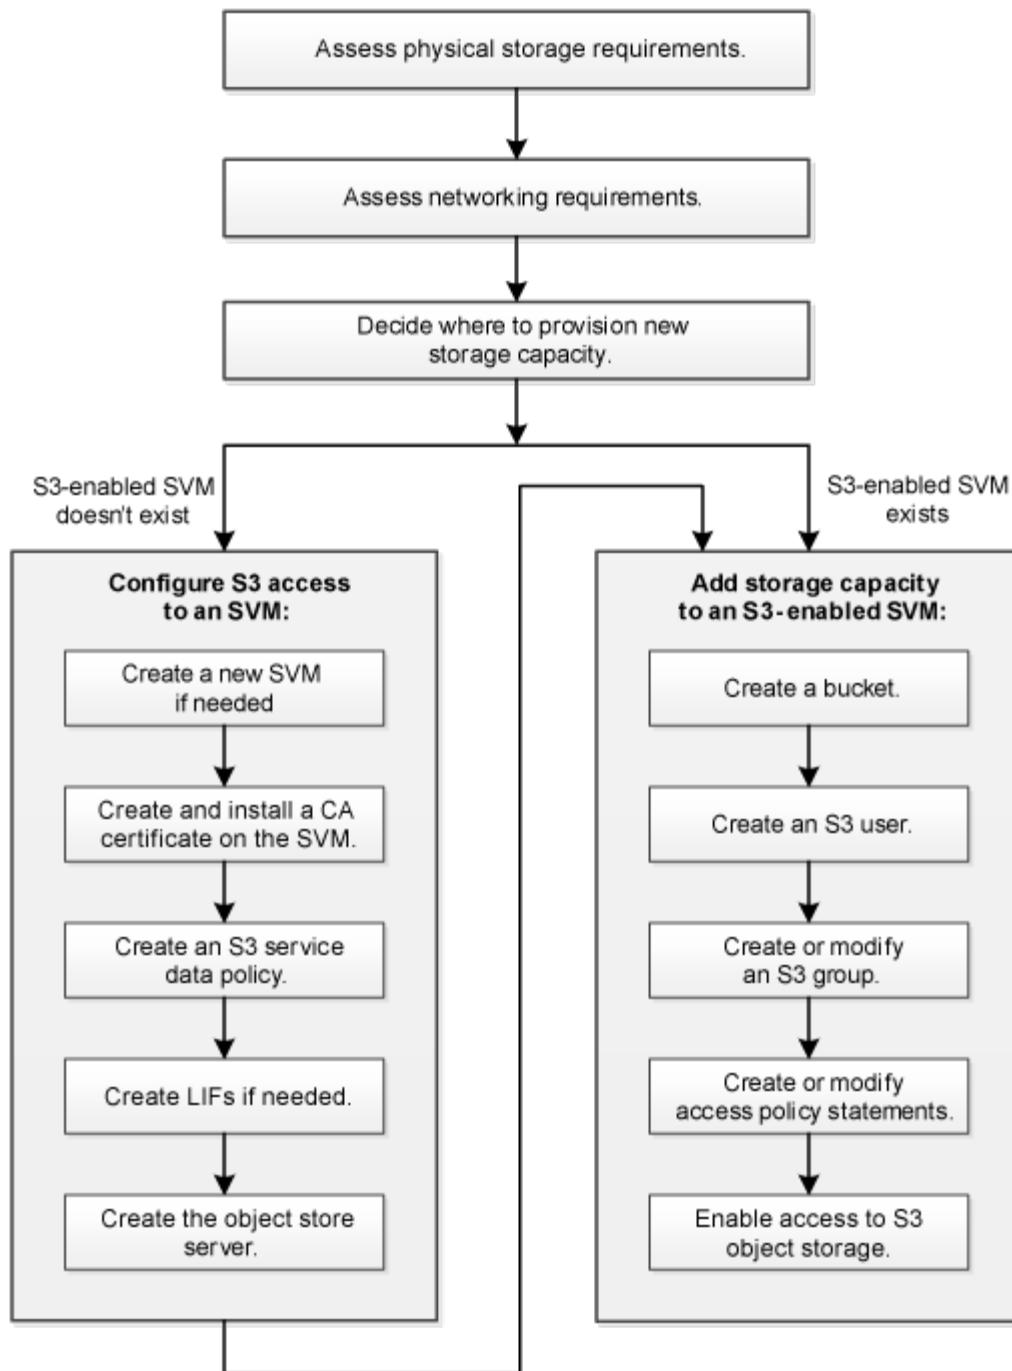

= S3 configuration workflow

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Configuring S3 involves assessing physical storage and networking requirements, and then choosing a workflow that is specific to your goal—configuring S3 access to a new or existing SVM, or adding a bucket and users to an existing SVM that is already fully configured for S3 access.

= Assess physical storage requirements

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin../media/

Before provisioning S3 storage for clients, you must ensure that there is sufficient space in existing aggregates for the new object store. If there is not, you can add disks to existing aggregates or create new aggregates of the desired type.

About this task

When you create an S3 bucket in an S3-enabled SVM, a FlexGroup volume is automatically created to support the bucket. You can let ONTAP select the underlying aggregates and FlexGroup components

automatically (the default) or you can select the underlying aggregates and FlexGroup components yourself.

If you decide to specify the aggregates and FlexGroup components — for example, if you have specific performance requirements for the underlying disks — you should make sure that your aggregate configuration conforms to best practice guidelines for provisioning a FlexGroup volume.

FlexGroup volumes management

[NetApp Technical Report 4571-a: NetApp ONTAP FlexGroup Volume Top Best Practices](#)

You can use the ONTAP S3 server to create a local FabricPool capacity tier; that is, in the same cluster as the performance tier. This can be useful, for example, if you have SSD disks attached to one HA pair and you want to tier *cold* data to HDD disks in another HA pair. In this use case, the S3 server and the bucket containing the local capacity tier should therefore be in a different HA pair than the performance tier. Local tiering is not supported on one-node and two-node clusters.

Steps

1. Display available space in existing aggregates:

```
storage aggregate show
```

If there is an aggregate with sufficient space, record its name for your S3 configuration.

```
cluster-1::> storage aggregate show
Aggregate      Size Available Used% State    #Vols  Nodes  RAID Status
-----  -----  -----  -----  -----  -----  -----  -----  -----
aggr_0       239.0GB   11.13GB  95%  online     1  node1  raid_dp,
                                         normal
aggr_1       239.0GB   11.13GB  95%  online     1  node1  raid_dp,
                                         normal
aggr_2       239.0GB   11.13GB  95%  online     1  node2  raid_dp,
                                         normal
aggr_3       239.0GB   11.13GB  95%  online     1  node2  raid_dp,
                                         normal
aggr_4       239.0GB   238.9GB  95%  online     5  node3  raid_dp,
                                         normal
aggr_5       239.0GB   239.0GB  95%  online     4  node4  raid_dp,
                                         normal
6 entries were displayed.
```

2. If there are no aggregates with sufficient space, add disks to an existing aggregate by using the `storage aggregate add-disks` command, or create a new aggregate by using the `storage aggregate create` command.

= Assess networking requirements

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

Before providing S3 storage to clients, you must verify that networking is correctly configured to meet the S3 provisioning requirements.

What you'll need

The following cluster networking objects must be configured:

- Physical and logical ports
- Broadcast domains
- Subnets (if required)
- IPspaces (as required, in addition to the default IPspace)
- Failover groups (as required, in addition to the default failover group for each broadcast domain)
- External firewalls

About this task

For remote FabricPool capacity (cloud) tiers and remote S3 clients, you must use a data SVM and configure data LIFs. For FabricPool cloud tiers, you must also configure intercluster LIFs; cluster peering is not required.

For local FabricPool capacity tiers, you must use the system SVM (called “Cluster”), but you have two options for LIF configuration:

- You can use the cluster LIFs.

In this option, no further LIF configuration is required, but there will be an increase in traffic on the cluster LIFs. Also, the local tier will not be accessible to other clusters.

- You can use data and intercluster LIFs.

This option requires additional configuration, including enabling the LIFs for the S3 protocol, but the local tier will also be accessible as a remote FabricPool cloud tier to other clusters.

Steps

1. Display the available physical and virtual ports:

```
network port show
```

- When possible, you should use the port with the highest speed for the data network.
- All components in the data network must have the same MTU setting for best performance.

2. If you are planning to use a subnet name to allocate the IP address and network mask value for a LIF, verify that the subnet exists and has sufficient addresses available:

```
network subnet show
```

Subnets contain a pool of IP addresses that belong to the same layer 3 subnet. Subnets are created by using the `network subnet create` command.

3. Display available IPspaces:

```
network ipspace show
```

You can use the default IPspace or a custom IPspace.

4. If you want to use IPv6 addresses, verify that IPv6 is enabled on the cluster:

```
network options ipv6 show
```

If required, you can enable IPv6 by using the `network options ipv6 modify` command.

= Decide where to provision new S3 storage capacity

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Before you create a new S3 bucket, you must decide whether to place it in a new or existing SVM. This decision determines your workflow.

Choices

- If you want to provision a bucket in a new SVM or an SVM that is not enabled for S3, complete the steps in the following topics.

[Configuring S3 access to an SVM](#)

[Adding storage capacity to an S3-enabled SVM](#)

Although S3 can coexist in an SVM with NFS and SMB, you might choose to create a new SVM if one of the following is true:

- You are enabling S3 on a cluster for the first time.
- You have existing SVMs in a cluster in which you do not want to enable S3 support.
- You have one or more S3-enabled-SVMs in a cluster, and you want another S3 server with different performance characteristics.

After enabling S3 on the SVM, proceed to provision a bucket.

- If you want to provision the initial bucket or an additional bucket on an existing S3-enabled SVM, complete the steps in the following topic.

[Adding storage capacity to an S3-enabled SVM](#)

= Configure S3 access to an SVM

= Create an SVM for S3

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Although S3 can coexist in an SVM with other protocols, you might want to create a new SVM to isolate the namespace and workload.

About this task

If you are only providing S3 object storage from this SVM, the S3 server does not require any DNS configuration. However, you might want to configure DNS on the SVM if other protocols are used.

Steps

1. Verify that S3 is licensed on your cluster:

```
system license show -package s3
```

If it is not, contact your sales representative.

2. Create an SVM:

```
vserver create -vserver svm_name -rootvolume root_volume_name -aggregate aggregate_name -rootvolume-security-style unix -language C.UTF-8 -ipspace ipspace_name
```

- Use the UNIX setting for the `-rootvolume-security-style` option.
- Use the default C.UTF-8 `-language` option.
- The `ipspace` setting is optional.

3. Verify the configuration and status of the newly created SVM:

```
vserver show -vserver svm_name
```

The Vserver Operational State field must display the running state. If it displays the initializing state, it means that some intermediate operation such as root volume creation failed, and you must delete the SVM and re-create it.

Examples

The following command creates an SVM for data access in the IPspace ipspaceA:

```
cluster-1::> vserver create -vserver svml.example.com -rootvolume root_svml -aggregate aggr1 -rootvolume-security-style unix -language C.UTF-8 -ipspace ipspaceA

[Job 2059] Job succeeded:
Vserver creation completed
```

The following command shows that an SVM was created with a root volume of 1 GB, and it was started automatically and is in running state. The root volume has a default export policy that does not include any rules, so the root volume is not exported upon creation. By default, the vsadmin user account is created and is in the locked state. The vsadmin role is assigned to the default vsadmin user account.

```

cluster-1::> vserver show -vserver svm1.example.com
                           Vserver: svm1.example.com
                           Vserver Type: data
                           Vserver Subtype: default

00a0983d9736
                           Root Volume: root_svm1
                           Aggregate: aggr1
                           NIS Domain: -
                           Root Volume Security Style: unix
                           LDAP Client: -
                           Default Volume Language Code: C.UTF-8
                           Snapshot Policy: default
                           Comment:
                           Quota Policy: default
                           List of Aggregates Assigned: -
                           Limit on Maximum Number of Volumes allowed: unlimited
                           Vserver Admin State: running
                           Vserver Operational State: running
                           Vserver Operational State Stopped Reason: -
                           Allowed Protocols: nfs, cifs
                           Disallowed Protocols: -
                           QoS Policy Group: -
                           Config Lock: false
                           IPspace Name: ipspaceA

```

= Create and install a CA certificate on the SVM

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

A Certificate Authority (CA) certificate is required to enable HTTPS traffic from S3 clients to the S3-enabled SVM.

About this task

Although it is possible to configure an S3 server to use HTTP only, and although it is possible to configure clients without a CA certificate requirement, it is a best practice to secure HTTPS traffic to ONTAP S3 servers with a CA certificate.

A CA certificate is not necessary for a local tiering use case, where IP traffic is going over cluster LIFs only.

The instructions in this procedure will create and install an ONTAP self-signed certificate. CA certificates from third-party vendors are also supported; see the administrator authentication documentation for more information.

[Administrator authentication and RBAC](#)

See the security certificate man pages for additional configuration options.

Steps

1. Create a self-signed digital certificate:

```
security certificate create -vserver svm_name -type root-ca -common-name  
ca_cert_name
```

The `-type root-ca` option creates and installs a self-signed digital certificate to sign other certificates by acting as a certificate authority (CA).

The `-common-name` option creates the SVM's Certificate Authority (CA) name and will be used when generating the certificate's complete name.

The default certificate size is 2048 bits.

Example

```
cluster-1::> security certificate create -vserver svm1.example.com  
-type root-ca -common-name svm1_ca
```

```
The certificate's generated name for reference:  
svm1_ca_159D1587CE21E9D4_svm1_ca
```

When the certificate's generated name is displayed; be sure to save it for later steps in this procedure.

2. Generate a certificate signing request:

```
security certificate generate-csr -common-name s3_server_name  
[additional_options]
```

The `-common-name` parameter for the signing request must be the S3 server name (FQDN).

You can provide the location and other detailed information about the SVM if desired.

You are prompted to keep a copy of your certificate request and private key for future reference.

3. Sign the CSR using SVM_CA to generate S3 Server's certificate:

```
security certificate sign -vserver svm_name -ca ca_cert_name -ca-serial  
ca_cert_serial_number [additional_options]
```

Enter the command options that you used in previous steps:

- `-ca` — the common name of the CA that you entered in Step 1.
- `-ca-serial` — the CA serial number from Step 1. For example, if the CA certificate name is `svm1_ca_159D1587CE21E9D4_svm1_ca`, the serial number is `159D1587CE21E9D4`.

By default, the signed certificate will expire in 365 days. You can select another value, and specify other signing details.

When prompted, copy and enter the certificate request string you saved in Step 2.

A signed certificate is displayed; save it for later use.

4. Install the signed certificate on the S3-enabled SVM:

```
security certificate install -type server -vserver svm_name
```

When prompted, enter the certificate and private key.

You have the option to enter intermediate certificates if a certificate chain is desired.

When the private key and the CA-signed digital certificate are displayed; save them for future reference.

5. Get the public key certificate:

```
security certificate show -vserver svm_name -common-name ca_cert_name -type root-ca -instance
```

Save the public key certificate for later client-side configuration.

Example

```

cluster-1::> security certificate show -vserver svml.example.com
-common-name svml_ca -type root-ca -instance

          Name of Vserver: svml.example.com
          FQDN or Custom Common Name: svml_ca
          Serial Number of Certificate: 159D1587CE21E9D4
          Certificate Authority: svml_ca
          Type of Certificate: root-ca
          (DEPRECATED) -Certificate Subtype: -
          Unique Certificate Name:
          svml_ca_159D1587CE21E9D4_svml_ca
          Size of Requested Certificate in Bits: 2048
          Certificate Start Date: Thu May 09 10:58:39 2020
          Certificate Expiration Date: Fri May 08 10:58:39 2021
          Public Key Certificate: -----BEGIN CERTIFICATE-----
MIIDZ ... ==
-----END CERTIFICATE-----
          Country Name: US
          State or Province Name:
          Locality Name:
          Organization Name:
          Organization Unit:
Contact Administrator's Email Address:
          Protocol: SSL
          Hashing Function: SHA256
          Self-Signed Certificate: true
          Is System Internal Certificate: false

```

= Create an S3 service data policy

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

You can create service policies for S3 data and management services. An S3 service data policy is required to enable S3 data traffic on LIFs.

About this task

An S3 service data policy is required if you are using data LIFs and intercluster LIFs. It is not required if you are using cluster LIFs for the local tiering use case.

When a service policy is specified for a LIF, the policy is used to construct a default role, failover policy, and data protocol list for the LIF.

Although multiple protocols can be configured for SVMs and LIFs, it is a best practice for S3 to be the only protocol when serving object data.

Steps

1. Change the privilege setting to advanced:

```
set -privilege advanced
```

2. Create a service data policy:

```
network interface service-policy create -vserver svm_name -policy
policy_name -services data-core,data-s3-server
```

The `data-core` and `data-s3-server` services are the only ones required to enable ONTAP S3, although other services can be included as needed.

= Create data LIFs

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If you created a new SVM, the dedicated LIFs you create for S3 access should be data LIFs.

What you'll need

- The underlying physical or logical network port must have been configured to the administrative `up` status.
- If you are planning to use a subnet name to allocate the IP address and network mask value for a LIF, the subnet must already exist.

Subnets contain a pool of IP addresses that belong to the same layer 3 subnet. They are created using the `network subnet create` command.

- The LIF service policy must already exist.

About this task

- You can create both IPv4 and IPv6 LIFs on the same network port.
- If you have a large number of LIFs in your cluster, you can verify the LIF capacity supported on the cluster by using the `network interface capacity show` command and the LIF capacity supported on each node by using the `network interface capacity details show` command (at the advanced privilege level).
- If you are enabling remote FabricPool capacity (cloud) tiering, you must also configure intercluster LIFs.

Steps

1. Create a LIF:

```
network interface create -vserver svm_name -lif lif_name -service-policy
service_policy_names -home-node node_name -home-port port_name {-address
IP_address -netmask IP_address | -subnet-name subnet_name} -firewall-policy
data -auto-revert {true|false}
```

- `-home-node` is the node to which the LIF returns when the `network interface revert` command is run on the LIF.

You can also specify whether the LIF should automatically revert to the home-node and home-port with the `-auto-revert` option.

- `-home-port` is the physical or logical port to which the LIF returns when the `network interface revert` command is run on the LIF.
- You can specify an IP address with the `-address` and `-netmask` options, or you enable allocation from a subnet with the `-subnet_name` option.
- When using a subnet to supply the IP address and network mask, if the subnet was defined with a gateway, a default route to that gateway is added automatically to the SVM when a LIF is created using that subnet.
- If you assign IP addresses manually (without using a subnet), you might need to configure a default route to a gateway if there are clients or domain controllers on a different IP subnet. The `network route create` man page contains information about creating a static route within an SVM.
- For the `-firewall-policy` option, use the same default data as the LIF role.

You can create and add a custom firewall policy later if desired.

- `-auto-revert` allows you to specify whether a data LIF is automatically reverted to its home node under circumstances such as startup, changes to the status of the management database, or when the network connection is made. The default setting is `false`, but you can set it to `false` depending on network management policies in your environment.
- The `-service-policy` option specifies the data and management services policy you created and any other policies you need.

2. If you want to assign an IPv6 address in the `-address` option:

- a. Use the `network ndp prefix show` command to view the list of RA prefixes learned on various interfaces.

The `network ndp prefix show` command is available at the advanced privilege level.

- b. Use the format `prefix:id` to construct the IPv6 address manually.

`prefix` is the prefix learned on various interfaces.

For deriving the `id`, choose a random 64-bit hexadecimal number.

3. Verify that the LIF was created successfully by using the `network interface show` command.

4. Verify that the configured IP address is reachable:

To verify an...	Use...
IPv4 address	<code>network ping</code>
IPv6 address	<code>network ping6</code>

Examples

The following command shows how to create an S3 data LIF that is assigned with the `my-S3-policy`

service policy:

```
network interface create -vserver svml.example.com -lif lif2 -home-node
node2 -homeport e0d -service-policy my-S3-policy -subnet-name ipspace1
```

The following command shows all the LIFs in cluster-1. Data LIFs datalif1 and datalif3 are configured with IPv4 addresses, and datalif4 is configured with an IPv6 address:

```
cluster-1::> network interface show

      Logical          Status        Network          Current          Current
Is       Vserver     Interface   Admin/Oper Address/Mask    Node           Port
Home

```

= Create intercluster LIFs for remote FabricPool tiering
:icons: font

```
:relative_path: ./s3-config/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

If you are enabling remote FabricPool capacity (cloud) tiering using ONTAP S3, you must configure intercluster LIFs. You can configure intercluster LIFs on ports shared with the data network. Doing so reduces the number of ports you need for intercluster networking.

What you'll need

- The underlying physical or logical network port must have been configured to the administrative `up` status.
- The LIF service policy must already exist.

About this task

Intercluster LIFs are not required for local Fabric pool tiering or for serving external S3 apps.

Steps

1. List the ports in the cluster:

```
network port show
```

The following example shows the network ports in `cluster01`:

```

cluster01::> network port show
                                         Speed
                                         (Mbps)
Node    Port      IPspace      Broadcast Domain Link      MTU
Admin/Oper
-----
-----
cluster01-01
    e0a        Cluster      Cluster      up       1500
auto/1000
    e0b        Cluster      Cluster      up       1500
auto/1000
    e0c        Default      Default      up       1500
auto/1000
    e0d        Default      Default      up       1500
auto/1000
cluster01-02
    e0a        Cluster      Cluster      up       1500
auto/1000
    e0b        Cluster      Cluster      up       1500
auto/1000
    e0c        Default      Default      up       1500
auto/1000
    e0d        Default      Default      up       1500
auto/1000

```

2. Create intercluster LIFs on the system SVM:

```

network interface create -vserver Cluster -lif LIF_name -service-policy
default-intercluster -home-node node -home-port port -address port_IP
-netmask netmask

```

The following example creates intercluster LIFs `cluster01_icl01` and `cluster01_icl02`:

```

cluster01::> network interface create -vserver Cluster -lif
cluster01_icl01 -service-
policy default-intercluster -home-node cluster01-01 -home-port e0c
-address 192.168.1.201
-netmask 255.255.255.0

cluster01::> network interface create -vserver Cluster -lif
cluster01_icl02 -service-
policy default-intercluster -home-node cluster01-02 -home-port e0c
-address 192.168.1.202
-netmask 255.255.255.0

```

3. Verify that the intercluster LIFs were created:

```
network interface show -service-policy default-intercluster
```

cluster01::> network interface show -service-policy default-intercluster				
	Logical	Status	Network	Current
Current Is	Vserver	Interface	Admin/Oper Address/Mask	Node
Port	Home			
-----	-----	-----	-----	-----
-----	-----	-----	-----	-----
cluster01				
	cluster01_icl01			
e0c	true	up/up	192.168.1.201/24	cluster01-01
	cluster01_icl02			
e0c	true	up/up	192.168.1.202/24	cluster01-02

4. Verify that the intercluster LIFs are redundant:

```
network interface show -service-policy default-intercluster -failover
```

The following example shows that the intercluster LIFs `cluster01_icl01` and `cluster01_icl02` on the `e0c` port will fail over to the `e0d` port.

```

cluster01::> network interface show -service-policy default-
intercluster -failover
      Logical          Home          Failover
      Failover
Vserver  Interface      Node:Port      Policy      Group
-----
-----  

cluster01
      cluster01_icl01 cluster01-01:e0c    local-only
192.168.1.201/24
      Failover Targets: cluster01-01:e0c,
                           cluster01-01:e0d
      cluster01_icl02 cluster01-02:e0c    local-only
192.168.1.201/24
      Failover Targets: cluster01-02:e0c,
                           cluster01-02:e0d

```

= Create the S3 object store server

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

The ONTAP object store server manages data as S3 objects, as opposed to file or block storage provided by ONTAP NAS and SAN servers.

What you'll need

You should have a self-signed CA certificate (created in previous steps) or a certificate signed by an external CA vendor. A CA certificate is not necessary for a local tiering use case, where IP traffic is going over cluster LIFs only.

About this task

When an object store server is created, a root user with UID 0 is created. No access key or secret key is generated for this root user. The ONTAP administrator must run the `object-store-server users regenerate-keys` command to set the access key and secret key for this user.

As a NetApp best practice, do not use this root user. Any client application that uses the access key or secret key of the root user has full access to all buckets and objects in the object store.

See the `vserver object-store-server` man pages for additional configuration and display options.

Steps

1. Create the S3 server:

```

vserver object-store-server create -vserver svm_name -object-store-server
s3_server_name -certificate-name ca_cert_name -comment text
[additional_options]

```

You can specify additional options when creating the S3 server or at any time later.

- The SVM name can be either a data SVM or Cluster (the system SVM name) if you are configuring local tiering.
- HTTPS is enabled by default on port 443. You can change the port number with the `-secure-listener-port` option.

When HTTPS is enabled, CA certificates are required for proper integration with SSL/TLS.

- HTTP is disabled by default; when enabled, the server listens on port 80. You can enable it with the `-is-http-enabled` option or change the port number with the `-listener-port` option.

When HTTP is enabled, all the request and responses are sent over the network in clear text.

2. Verify that S3 is configured as desired:

```
vserver object-store-server show
```

Example

The following command verifies the configuration values of all object storage servers:

```
cluster1::> vserver object-store-server show

Vserver: vs1

Object Store Server Name: s3.example.com
Administrative State: up
Listener Port For HTTP: 80
Secure Listener Port For HTTPS: 443
HTTP Enabled: false
HTTPS Enabled: true
Certificate for HTTPS Connections: svm1_ca
Comment: Server comment
```

= Add storage capacity to an S3-enabled SVM

= Create a bucket

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

S3 objects are kept in *buckets*--they are not nested as files inside a directory inside other directories.

What you'll need

An SVM containing an S3 server must already exist.

About this task

When you create a bucket, you have two provisioning options:

- Let ONTAP select the underlying aggregates and FlexGroup components (default)
 - ONTAP creates and configures a FlexGroup volume for the first bucket by automatically selecting the aggregates. It will automatically select the highest service level available for your platform, or you can specify the storage service level. Any additional buckets you add later in the SVM will have the same underlying FlexGroup volume.
 - Alternatively, you can specify whether the bucket will be used for tiering, in which case ONTAP tries to select low-cost media with optimal performance for the tiered data.
- You select the underlying aggregates and FlexGroup components (requires advanced privilege command options)
 - You have the option to manually select the aggregates on which the bucket and containing FlexGroup volume must be created, and then specifying the number of constituents on each aggregate. When adding additional buckets:
 - If you specify aggregates and constituents for a new bucket, a new FlexGroup will be created for the new bucket.
 - If you do not specify aggregates and constituents for a new bucket, the new bucket will be added to an existing FlexGroup.

See the FlexGroup documentation for more information.

[FlexGroup volumes management](#)

When you specify aggregates and constituents when creating a bucket, no QoS policy groups, default or custom, are applied. You can do so later with the `vserver object-store-server bucket modify` command.

Storage service levels are predefined adaptive Quality of Service (QoS) policy groups, with `value`, `performance`, and `extreme` default levels. Instead of one of the default storage service levels, you can also define a custom QoS policy group and apply it to a bucket.

[Storage service definitions](#)

If you are configuring local capacity tiering, you create buckets and users in a data SVM, not in the system SVM where the S3 server is located.

[Performance management](#)

See the `vserver object-store-server bucket` man pages for additional configuration and display options.

Steps

1. If you plan to select aggregates and FlexGroup components yourself, set the privilege level to advanced (otherwise, admin privilege level is sufficient): set `-privilege advanced`
2. Create a bucket:

```
vserver object-store-server bucket create -vserver svm_name -bucket
bucket_name [-size integer[KB|MB|GB|TB|PB]] [-comment text]
[additional_options]
```

The SVM name can be either a data SVM or `cluster` (the system SVM name) if you are configuring local tiering.

If you specify no options, ONTAP creates a 5GB bucket with the service level set to the highest level available for your system.

If you want ONTAP to create a bucket based on performance or usage, use one of the following options:

- service level

Include the `-storage-service-level` option with one of the following values: `value`, `performance`, or `extreme`.

- tiering

Include the `-used-as-capacity-tier true` option.

If you want to specify the aggregates on which to create the underlying FlexGroup volume, use the following options:

- The `-aggr-list` parameter specifies the list of aggregates to be used for FlexGroup volume constituents.

Each entry in the list creates a constituent on the specified aggregate. You can specify an aggregate multiple times to have multiple constituents created on the aggregate.

For consistent performance across the FlexGroup volume, all of the aggregates must use the same disk type and RAID group configurations.

- The `-aggr-list-multiplier` parameter specifies the number of times to iterate over the aggregates that are listed with the `-aggr-list` parameter when creating a FlexGroup volume.

The default value of the `-aggr-list-multiplier` parameter is 4.

3. Add a QoS policy group if needed:

```
vserver object-store-server bucket modify -bucket bucket_name -qos-policy -group qos_policy_group
```

4. Verify bucket creation:

```
vserver object-store-server bucket show [-instance]
```

Example

The following example creates a bucket for SVM vs1 of size 1TB and specifying the aggregate:

```
cluster-1::>*> vserver object-store-server bucket create -vserver svml.example.com -bucket testbucket -aggr-list aggr1 -size 1TB
```

= Create an S3 user

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

User authorization is required on all ONTAP object stores in order to restrict connectivity to authorized clients.

What you'll need

An S3-enabled SVM must already exist.

About this task

An S3 user can be granted access to any bucket in an SVM but not in multiple SVMs.

When you create an S3 user, an access-key and a secret-key will be generated. They must be shared with the user along with the object store's FQDN and bucket name. S3 users' keys can be displayed with the vserver object-store-server user show command.

You can grant specific access permissions to S3 users in a bucket policy or an object server policy.

When an object store server is created, a root user (UID 0) is created, a privileged user with access all buckets. Rather than administering ONTAP S3 as root user, it is a best practice to create an admin user role with specific privileges.

Step

1. Create an S3 user:

```
vserver object-store-server user create -vserver svm_name -user user_name  
[-comment text]
```

= Create or modify S3 groups

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can simplify bucket access by creating groups of users with appropriate access authorizations.

What you'll need

S3 users in an S3-enabled SVM must already exist.

About this task

Users in an S3 group can be granted access to any bucket in an SVM but not in multiple SVMs. Group access permissions can be configured in two ways:

- At the bucket level

After creating a group of S3 users, you specify group permissions in bucket policy statements and they apply only to that bucket.

- At the SVM level

After creating a group of S3 users, you specify object server policy names in the group definition. Those policies determine the buckets and access for the group members.

Step

1. Create an S3 group:

```
vserver object-store-server group create -vserver svm_name -name group_name  
-users user_name\$(s) [-policies policy_names] [-comment text]
```

The `-policies` option can be omitted in configurations with only one bucket in an object store; the group name can be added to the bucket policy.

The `-policies` option can be added later with the `vserver object-store-server group modify` command after object storage server policies are created.

= Create or modify access policy statements

= About bucket and object store server policies

:icons: font
:relative_path: ./s3-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

User and group access to S3 resources is controlled by bucket and object store server policies. If you have a small number of users or groups, controlling access at the bucket level is probably sufficient, but if you have many users and groups, it is easier to control access at the object store server level.

= Modify a bucket policy

:icons: font
:relative_path: ./s3-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can add access rules to the default bucket policy. The scope of its access control is the containing bucket, so it is most appropriate when there is a single bucket.

What you'll need

An S3-enabled SVM containing an S3 server and a bucket must already exist.

About this task

You can add new statements for new users and groups, or you can modify the attributes of existing statements. For more options, see the `vserver object-store-server bucket policy` man pages.

Steps

1. Add a statement to a bucket policy:

```
vserver object-store-server bucket policy add-statement -vserver svm_name  
-bucket bucket_name -effect {allow|deny} -action object_store_actions  
-principal user_and_group_names -resource object_store_resources [-sid  
text] [-index integer]
```

The following parameters define access permissions:

-effect	The statement may allow or deny access
---------	--

-action	You can specify * to mean all actions, or a list of one or more of the following: GetObject, PutObject, DeleteObject, ListBucket, GetBucketAcl, GetObjectAcl, ListBucketMultipartUploads, and ListMultipartUploadParts.
-principal	<p>A list of one or more S3 users or groups.</p> <ul style="list-style-type: none"> • A maximum of 10 users or groups can be specified. • If an S3 group is specified, it must be in the form group/group_name. • * can be specified to mean public access; that is, access without an access-key and secret-key. • If no principal is specified, all S3 users in the SVM are granted access.
-resource	The bucket and any object it contains. The wildcard characters * and ? can be used to form a regular expression for specifying a resource.

You can optionally specify a text string as comment with the -sid option.

Examples

The following example creates an object store server bucket policy statement for the SVM svm1.example.com and bucket1 which specifies allowed access to a readme folder for object store server user user1.

```
cluster1::> vserver object-store-server bucket policy statement create
-vserver svm1.example.com -bucket bucket1 -effect allow -action
GetObject,PutObject,DeleteObject,ListBucket -principal user1 -resource
bucket1/readme/* -sid "fullAccessToReadmeForUser1"
```

The following example creates an object store server bucket policy statement for the SVM svm1.example.com and bucket1 which specifies allowed access to all objects for object store server group group1.

```
cluster1::> vserver object-store-server bucket policy statement create
-vserver svm1.example.com -bucket bucket1 -effect allow -action
GetObject,PutObject,DeleteObject,ListBucket -principal group/group1
-resource bucket1/* -sid "fullAccessForGroup1"
```

= Create or modify an object store server policy

```
:icons: font
:relative_path: ./s3-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/
```

You can create policies that can apply to one or more buckets in an object store. Object store server policies can be attached to groups of users, thereby simplifying the management of resource access across multiple buckets.

What you'll need

An S3-enabled SVM containing an S3 server and a bucket must already exist.

About this task

You can enable access policies at the SVM level by specifying a default or custom policy in an object storage server group. The policies do not take effect until they are specified in the group definition.

When you use object storage server policies, you specify principals (that is, users and groups) in the group definition, not in the policy itself.

There are three read-only default policies for access to ONTAP S3 resources:

- FullAccess
- NoS3Access
- ReadOnlyAccess

You can also create new custom policies, then add new statements for new users and groups, or you can modify the attributes of existing statements. For more options, see the `vserver object-store-server policy` man pages.

Steps

1. Create an object storage server policy:

```
vserver object-store-server policy create -vserver svm_name -policy
policy_name [-comment text]
```

2. Create a statement for the policy:

```
vserver object-store-server policy statement create -vserver svm_name]
-policy policy_name -effect {allow|deny} -action object_store_actions
-resource object_store_resources [-sid text]
```

The following parameters define access permissions:

-effect	The statement may allow or deny access
---------	--

-action	You can specify * to mean all actions, or a list of one or more of the following: GetObject, PutObject, DeleteObject, ListBucket, GetBucketAcl, GetObjectAcl, ListAllMyBuckets, ListBucketMultipartUploads, and ListMultipartUploadParts.
-resource	The bucket and any object it contains. The wildcard characters * and ? can be used to form a regular expression for specifying a resource.

You can optionally specify a text string as comment with the `-sid` option.

By default, new statements are added to the end of the list of statements, which are processed in order. When you add or modify statements later, you have the option to modify the statement's `-index` setting to change the processing order.

= Enable client access to S3 object storage

= Enable ONTAP S3 access for remote FabricPool tiering

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

For ONTAP S3 to be used as a remote FabricPool capacity (cloud) tier, the ONTAP S3 administrator must provide information about the S3 server configuration to the remote ONTAP cluster administrator.

About this task

The following S3 server information is required to configure FabricPool cloud tiers:

- server name (FQDN)
- bucket name
- CA certificate
- access key
- password (secret access key)

In addition, the following networking configuration is required:

- There must be an entry for the remote ONTAP S3 server's hostname in the DNS server configured for the admin SVM, including the S3 server's FQDN name and the IP addresses on its LIFs.
- Intercluster LIFs must be configured on both local and remote clusters, although cluster peering is not required.

See the FabricPool documentation about configuring ONTAP S3 as a cloud tier.

[Managing Storage Tiers By Using FabricPool](#)

```
= Enable ONTAP S3 access for local FabricPool tiering
:icons: font
:relative_path: ./s3-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/
```

For ONTAP S3 to be used as a local FabricPool capacity tier, you must define an object store based on the bucket you created, and then attach the object store to a performance tier aggregate to create a FabricPool.

What you'll need

You must have the ONTAP S3 server name and a bucket name, and the S3 server must have been created using cluster LIFs (with the `-vserver Cluster` parameter).

About this task

The object-store configuration contains information about the local capacity tier, including the S3 server and bucket names and authentication requirements.

An object-store configuration once created must not be reassigned with a different object-store or bucket. You can create multiple buckets for local tiers, but you cannot create multiple object stores in a single bucket.

A FabricPool license is not required for a local capacity tier.

Steps

1. Create the object store for the local capacity tier:

```
storage aggregate object-store config create -object-store-name store_name
-ipspace Cluster -provider-type ONTAP_S3 -server S3_server_name -container
-name bucket_name -access-key access_key -secret-password password
```

- The `-container-name` is the S3 bucket you created.
- The `-access-key` parameter authorizes requests to the ONTAP S3 server.
- The `-secret-password` parameter (secret access key) authenticates requests to the ONTAP S3 server.
- You can set the `-is-certificate-validation-enabled` parameter to `false` to disable certificate checking for ONTAP S3.

```
cluster1::> storage aggregate object-store config create
-object-store-name MyLocalObjStore -ipspace Cluster -provider-type
ONTAP_S3 -server s3.example.com
-container-name bucket1 -access-key myS3key -secret-password
myS3pass
```

2. Display and verify the object store configuration information:

```
storage aggregate object-store config show
```

3. Optional: To see how much data in a volume is inactive, follow the steps in [Determining how much data in a volume is inactive by using inactive data reporting](#).

Seeing how much data in a volume is inactive can help you decide which aggregate to use for FabricPool local tiering.

4. Attach the object store to an aggregate:

```
storage aggregate object-store attach -aggregate aggr_name -object-store  
-name store_name
```

You can use the `allow-flexgroup true` option to attach aggregates that contain FlexGroup volume constituents.

```
cluster1::> storage aggregate object-store attach  
-aggregate aggr1 -object-store-name MyLocalObjStore
```

5. Display the object store information and verify that the attached object store is available:

```
storage aggregate object-store show
```

```
cluster1::> storage aggregate object-store show
```

Aggregate	Object Store Name	Availability State
aggr1	MyLocalObjStore	available

= Enable client access from an S3 app

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

For S3 client apps to access the ONTAP S3 server, the ONTAP S3 administrator must provide configuration information to the S3 user.

What you'll need

The S3 client app must be capable of authenticating with the ONTAP S3 server using AWS Signature Version 4. Earlier signature versions are not supported by ONTAP S3.

The ONTAP S3 administrator must have created S3 users and granted them access permissions, as an individual users or as a group member, in the bucket policy or the object storage server policy.

The S3 client app must be capable of resolving the ONTAP S3 server name, which requires that ONTAP S3 administrator provide the S3 server name (FQDN) and IP addresses for the S3 server's LIFs.

About this task

To access an ONTAP S3 bucket, a user on the S3 client app enters information provided by the ONTAP S3 administrator.

Beginning with ONTAP 9.9.1, the ONTAP S3 server supports the following AWS client functionality:

- user-defined object metadata

A set of key-value pairs can be assigned to objects as metadata when they are created using PUT (or POST). When a GET/HEAD operation is performed on the object, the user-defined metadata is returned along with the system metadata.

- object tagging

A separate set of key-value pairs can be assigned as tags for categorizing objects. Unlike metadata, tags are created and read with REST APIs independently of the object, and they implemented when objects are created or any time after.

To enable clients to get and put tagging information, the actions `GetObjectTagging`, `PutObjectTagging`, and `DeleteObjectTagging` need to be allowed using the bucket or group policies.

For more information, see the AWS S3 documentation.

Steps

1. Authenticate the S3 client app with the ONTAP S3 server by entering the S3 server name and the CA certificate.
2. Authenticate a user on the S3 client app by entering the following information:
 - S3 server name (FQDN) and bucket name
 - the user's access key and secret key

= Storage service definitions

:icons: font

:relative_path: ./s3-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

ONTAP includes predefined storage services that are mapped to corresponding minimum performance factors.

The actual set of storage services available in a cluster or SVM is determined by the type of storage that makes up an aggregate in the SVM.

The following table shows how the minimum performance factors are mapped to the predefined storage services:

Storage service	Expected IOPS (SLA)	Peak IOPS (SLO)	Minimum volume IOPS	Estimated latency	Are expected IOPS enforced?
value	128 per TB	512 per TB	75	17 ms	On AFF: Yes Otherwise: No
performance	2048 per TB	4096 per TB	500	2 ms	Yes
extreme	6144 per TB	12288 per TB	1000	1 ms	Yes

The following table defines the available storage service level for each type of media or node:

Media or node	Available storage service level
Disk	value
Virtual machine disk	value
FlexArray LUN	value
Hybrid	value
Capacity-optimized Flash	value
Solid-state drive (SSD) - non-AFF	value
Performance-optimized Flash - SSD (AFF)	extreme, performance, value

= Protect buckets with S3 SnapMirror

= S3 SnapMirror overview

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

:linkattrs:

:relative_path: ./s3-snapmirror/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Beginning with ONTAP 9.10.1, you can protect buckets in ONTAP S3 object stores using familiar SnapMirror mirroring and backup functionality. In addition, unlike standard SnapMirror, S3 SnapMirror can have non-NetApp destinations.

S3 SnapMirror supports active mirrors and backup tiers from ONTAP S3 buckets to the following destinations:

Target	Supports active mirrors and takeover?	Supports backup and restore?
ONTAP S3 <ul style="list-style-type: none"> • buckets in the same SVM • buckets in different SVMs on the same cluster • buckets in SVMs on different clusters 	✓	✓
StorageGRID		✓
AWS S3		✓

You can protect existing buckets on ONTAP S3 servers or you can create new buckets with data

protection enabled immediately.

S3 SnapMirror supports fan-out and cascade relationships. For an overview, see [Fan-out and cascade data protection deployments](#).

== S3 SnapMirror requirements

- ONTAP version
 - ONTAP 9.10.1 or later must be running source and destination clusters.
- Licensing
 - The following license bundles are required on ONTAP source and destination systems:
 - Core Bundle
 - For ONTAP S3 protocol and storage.
 - Data Protection Bundle
 - For S3 SnapMirror to target other NetApp object store targets (ONTAP S3, StorageGRID, and Cloud Volumes ONTAP).
 - Data Protection Bundle and Hybrid Cloud Bundle
 - For S3 SnapMirror to target 3rd party object stores (AWS S3).
- ONTAP S3
 - ONTAP S3 servers must be running source and destination SVMs.
 - It is recommended but not required that CA certificates for TLS access are installed on systems that host S3 servers.
 - The CA certificates used to sign the S3 servers' certificates must be installed on the admin storage VM of the clusters that host S3 servers.
 - You can use a self-signed CA certificate or a certificate signed by an external CA vendor.
 - If the source or destination storage VMs are not listening on HTTPS, it is not necessary to install CA certificates.
- Peering (for ONTAP S3 targets)
 - Intercluster LIFs must be configured (for remote ONTAP targets).
 - Source and destination clusters are peered (for remote ONTAP targets).
 - Source and destination storage VMs are peered (for all ONTAP targets).
- SnapMirror policy
 - An S3-specific SnapMirror policy is required for all S3 SnapMirror relationships, but you can use the same policy for multiple relationships.
 - You can create your own policy or accept the default **Continuous** policy, which includes the following values:
 - Throttle (upper limit on throughput/bandwidth) - unlimited.
 - Time for recovery point objective: 1 hour (3600 seconds).
- Root user keys
 - Storage VM root user access keys are required for S3 SnapMirror relationships; ONTAP does not assign them by default. The first time you create an S3 SnapMirror relationship, you must verify that the keys exist on both source and destination storage VMs and regenerate them if they do not. If you need to regenerate them, you must ensure that all clients and all SnapMirror object-store configurations using the access and secret key pair are updated with the new keys.

For information about S3 server configuration, see the following topics:

- [Enable an S3 server on a storage VM](#)
- [About the S3 configuration process \(CLI\)](#)

For information about cluster and storage VM peering, see the following topic:

- [Prepare for mirroring and vaulting \(System Manager, steps 1-6\)](#)
- [Cluster and SVM peering \(CLI\)](#)

== S3 SnapMirror considerations and restrictions

When you create new buckets, you can control access by creating users and groups. For more information, see the following topics:

- [Add S3 users and groups \(System Manager\)](#)
- [Create an S3 user \(CLI\)](#)
- [Create or modify S3 groups \(CLI\)](#)

The following standard SnapMirror functionality is not supported in the current S3 SnapMirror release:

- Fan-in deployments (data protection relationships between multiple source buckets and a single destination bucket)

S3 Snapmirror can support multiple bucket mirrors from multiple clusters to a single secondary cluster, but each source bucket must have its own destination bucket on the secondary cluster.

= Mirror and backup protection on a remote cluster

= Create a mirror relationship for a new bucket (remote cluster)

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./s3-snapmirror/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

When you create new S3 buckets, you can protect them immediately to an S3 SnapMirror destination on a remote cluster.

What you'll need

- Requirements for ONTAP versions, licensing, and S3 server configuration have been completed.
- A peering relationship exists between source and destination clusters, and a peering relationship exists between source and destination storage VMs.
- CA Certificates are needed for the source and destination VMs. You can use self-signed CA certificates or certificates signed by an external CA vendor.

About this task

You will need to perform tasks on both source and destination systems.

== System Manager procedure

1. If this is the first S3 SnapMirror relationship for this storage VM, verify that root user keys exist for both source and destination storage VMs and regenerate them if they do not:
 - a. Click **Storage > Storage VMs** and then select the storage VM.
 - b. In the **Settings** tab, click in the **S3** tile.
 - c. In the **Users** tab, verify that there is an access key for the root user.
 - d. If there is not, click next to **root**, then click **Regenerate Key**.
Do not regenerate the key if one already exists.

2. Edit the storage VM to add users, and to add users to groups, in both the source and destination storage VMs:

Click **Storage > storage VMs**, click the storage VM, click **Settings** and then click under S3.

See [Add S3 users and groups](#) for more information.

3. On the source cluster, create an S3 SnapMirror policy if you don't have an existing one and you don't want to use the default policy:

- a. Click **Protection > Overview**, and then click **Local Policy Settings**.

- b. Click next to **Protection Policies**, then click **Add**.

- Enter the policy name and description.
- Select the policy scope, cluster or SVM
- Select **Continuous** for S3 SnapMirror relationships.
- Enter your **Throttle** and **Recovery Point Objective** values.

4. Create a bucket with SnapMirror protection:

- a. Click **Storage > Buckets**, then click **Add**. Verifying permissions is optional but recommended.

- b. Enter a name, select the storage VM, enter a size, then click **More Options**.

- c. Under **Permissions**, click **Add**.

- **Principal** and **Effect** - select values corresponding to your user group settings or accept the defaults.
- **Actions**- make sure the following values are shown:
`GetObject,PutObject,DeleteObject,ListBucket,GetBucketAcl,GetObjectAcl, ListBucketMultipartUploads, ListMultipartUploadParts`
- **Resources** - use the defaults (`bucketname, bucketname/*`) or other values you need.

See [Manage user access to buckets](#) for more information about these fields.

- d. Under **Protection**, check **Enable SnapMirror (ONTAP or Cloud)**. Then enter the following values:

- Destination
 - **TARGET: ONTAP System**
 - **CLUSTER**: Select the remote cluster.
 - **STORAGE VM**: Select a storage VM on the remote cluster.
 - **S3 SERVER CA CERTIFICATE**: Copy and paste the contents of the *source* certificate.
- Source

- **S3 SERVER CA CERTIFICATE:** Copy and paste the contents of the *destination* certificate.

Check **Use the same certificate on the destination** if you are using a certificate signed by an external CA vendor.

If you click **Destination Settings**, you can also enter your own values in place of the defaults for bucket name, capacity, and performance service level.

When you click **Save**, a new bucket is created in the source storage VM, and it is mirrored to a new bucket that is created in the destination storage VM.

== CLI procedure

1. If this is the first S3 SnapMirror relationship for this SVM, verify that root user keys exist for both source and destination SVMs and regenerate them if they do not:

```
vserver object-store-server user show
```

Verify that there is an access key for the root user. If there is not, enter:

```
vserver object-store-server user regenerate-keys -vserver svm_name -user
root
```

Do not regenerate the key if one already exists.

2. Create buckets in both the source and destination SVMs:

```
vserver object-store-server bucket create -vserver svm_name -bucket
bucket_name [-size integer[KB|MB|GB|TB|PB]] [-comment text]
[additional_options]
```

3. Add access rules to the default bucket policies in both the source and destination SVMs:

```
vserver object-store-server bucket policy add-statement -vserver svm_name
-bucket bucket_name -effect {allow|deny} -action object_store_actions
-principal user_and_group_names -resource object_store_resources [-sid
text] [-index integer]
```

Example

```
src_cluster::> vserver object-store-server bucket policy add-
statement -bucket test-bucket -effect allow -action
GetObject,PutObject,DeleteObject,ListBucket,GetBucketAcl,GetObjectAc
l,ListBucketMultipartUploads,ListMultipartUploadParts -principal -
-resource test-bucket, test-bucket /*
```

4. On the source SVM, create an S3 SnapMirror policy if you don't have an existing one and you don't want to use the default policy:

```
snapmirror policy create -vserver svm_name -policy policy_name -type
continuous [-rpo integer] [-throttle throttle_type] [-comment text]
[additional_options]
```

Parameters:

- type continuous – the only policy type for S3 SnapMirror relationships (required).
- -rpo – specifies the time for recovery point objective, in seconds (optional).
- -throttle – specifies the upper limit on throughput/bandwidth, in kilobytes/seconds (optional).

Example

```
src_cluster::> snapmirror policy create -vserver vs0 -type  
continuous -rpo 0 -policy test-policy
```

5. Install CA server certificates on the admin SVMs of the source and destination clusters:

- a. On the source cluster, install the CA certificate that signed the *destination* S3 server certificate:
`security certificate install -type server-ca -vserver src_admin_svm
-cert-name dest_server_certificate`
- b. On the destination cluster, install the CA certificate that signed the *source* S3 server certificate:
`security certificate install -type server-ca -vserver dest_admin_svm
-cert-name src_server_certificate`

If you are using a certificate signed by an external CA vendor, install the same certificate on the source and destination admin SVM.

See the `security certificate install` man page for details.

6. On the source SVM, create an S3 SnapMirror relationship:

```
snapmirror create -source-path src_svm_name:/bucket/bucket_name  
-destination-path dest_peer_svm_name:/bucket/bucket_name, ...} [-policy  
policy_name]
```

You can use a policy you created or accept the default.

Example

```
src_cluster::> snapmirror create -source-path vs0-src:/bucket/test-  
bucket -destination-path vs1-dest:bucket/test-bucket-mirror -policy  
test-policy
```

7. Verify that mirroring is active:

```
snapmirror show -policy-type continuous -fields status
```

= Create a mirror relationship for an existing bucket (remote cluster)

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./s3-snapmirror/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can begin protecting existing S3 buckets at any time; for example, if you upgraded an S3 configuration from a release earlier than ONTAP 9.10.1.

What you'll need

- Requirements for ONTAP versions, licensing, and S3 server configuration have been completed.
- A peering relationship exists between source and destination clusters, and a peering relationship exists between source and destination storage VMs.
- CA Certificates are needed for the source and destination VMs. You can use self-signed CA certificates or certificates signed by an external CA vendor.

About this task

You will need to perform tasks on both source and destination clusters.

== System Manager procedure

1. If this is the first S3 SnapMirror relationship for this storage VM, verify that root user keys exist for both source and destination storage VMs and regenerate them if they do not:

- a. Click **Storage > Storage VMs** and then select the storage VM.
- b. In the **Settings** tab, click  in the **S3** tile.
- c. In the **Users** tab, verify that there is an access key for the root user.
- d. If there is not, click  next to **root**, then click **Regenerate Key**.
Do not regenerate the key if one already exists.

2. Verify that user and group access is correct in both the source and destination storage VMs:
Click **Storage > storage VMs**, click the storage VM, click **Settings** and then click  under **S3**.

See [Add S3 users and groups](#) for more information.

3. On the source cluster, create an S3 SnapMirror policy if you don't have an existing one and you don't want to use the default policy:

- a. Click **Protection > Overview**, and then click **Local Policy Settings**.
- b. Click  next to **Protection Policies**, then click **Add**.
- c. Enter the policy name and description.
- d. Select the policy scope, cluster or SVM
- e. Select **Continuous** for S3 SnapMirror relationships.
- f. Enter your **Throttle** and **Recovery Point Objective** values.

4. Verify that the bucket access policy of the existing bucket still meets your needs:

- a. Click **Storage > Buckets** and then select the bucket you want to protect.
- b. In the **Permissions** tab, click  **Edit**, then click **Add** under **Permissions**.
 - **Principal and Effect:** select values corresponding to your user group settings, or accept the defaults.
 - **Actions:** make sure the following values are shown:
`GetObject,PutObject,DeleteObject,ListBucket,GetBucketAcl,GetObjectAcl, ListBucketMultipartUploads, ListMultipartUploadParts`
 - **Resources:** use the defaults (`bucketname, bucketname/*`) or other values you need.

See [Manage user access to buckets](#) for more information about these fields.

5. Protect an existing bucket with S3 SnapMirror protection:
 - a. Click **Storage > Buckets** and then select the bucket you want to protect..
 - b. Click **Protect** and enter the following values:
 - Destination
 - **TARGET:** ONTAP System
 - **CLUSTER:** Select the remote cluster.
 - **STORAGE VM:** Select a storage VM on the remote cluster.
 - **S3 SERVER CA CERTIFICATE:** Copy and paste the contents of the *source* certificate.
 - Source
 - **S3 SERVER CA CERTIFICATE:** Copy and paste the contents of the *destination* certificate.

Check **Use the same certificate on the destination** if you are using a certificate signed by an external CA vendor.

If you click **Destination Settings**, you can also enter your own values in place of the defaults for bucket name, capacity, and performance service level.

When you click **Save**, the existing bucket is mirrored to a new bucket in the destination storage VM.

== CLI procedure

1. If this is the first S3 SnapMirror relationship for this SVM, verify that root user keys exist for both source and destination SVMs and regenerate them if they do not:

```
vserver object-store-server user show
```

Verify that there is an access key for the root user. If there is not, enter:

```
vserver object-store-server user regenerate-keys -vserver svm_name -user root
```

Do not regenerate the key if one already exists.

2. Create a bucket on the destination SVM to be the mirror target:

```
vserver object-store-server bucket create -vserver svm_name -bucket dest_bucket_name [-size integer[KB|MB|GB|TB|PB]] [-comment text] [additional_options]
```

3. Verify that the access rules of the default bucket policies are correcte in both the source and destination SVMs:

```
vserver object-store-server bucket policy add-statement -vserver svm_name -bucket bucket_name -effect {allow|deny} -action object_store_actions -principal user_and_group_names -resource object_store_resources [-sid text] [-index integer]
```

Example

```
src_cluster::> vserver object-store-server bucket policy add-
statement -bucket test-bucket -effect allow -action
GetObject,PutObject,DeleteObject,ListBucket,GetBucketAcl,GetObjectAc
l,ListBucketMultipartUploads,ListMultipartUploadParts -principal -
-resource test-bucket, test-bucket /*
```

4. On the source SVM, create an S3 SnapMirror policy if you don't have an existing one and you don't want to use the default policy:

```
snapmirror policy create -vserver svm_name -policy policy_name -type
continuous [-rpo integer] [-throttle throttle_type] [-comment text]
[additional_options]
```

Parameters:

- continuous – the only policy type for S3 SnapMirror relationships (required).
- -rpo – specifies the time for recovery point objective, in seconds (optional).
- -throttle – specifies the upper limit on throughput/bandwidth, in kilobytes/seconds (optional).

Example

```
src_cluster::> snapmirror policy create -vserver vs0 -type
continuous -rpo 0 -policy test-policy
```

5. Install CA certificates on the admin SVMs of source and destination clusters:

- a. On the source cluster, install the CA certificate that signed the *destination* S3 server certificate:

```
security certificate install -type server-ca -vserver src_admin_svm
-cert-name dest_server_certificate
```

- b. On the destination cluster, install the CA certificate that signed the *source* S3 server certificate:

```
security certificate install -type server-ca -vserver dest_admin_svm
-cert-name src_server_certificate
```

If you are using a certificate signed by an external CA vendor, install the same certificate on the source and destination admin SVM.

See the `security certificate install` man page for details.

6. On the source SVM, create an S3 SnapMirror relationship:

```
snapmirror create -source-path src_svm_name:/bucket/bucket_name
-destination-path dest_peer_svm_name:/bucket/bucket_name, ...} [-policy
policy_name]
```

You can use a policy you created or accept the default.

Example

```
src_cluster::> snapmirror create -source-path vs0:/bucket/test-
bucket -destination-path vs1:/bucket/test-bucket-mirror -policy
test-policy
```

7. Verify that mirroring is active:

```
snapmirror show -policy-type continuous -fields status
```

= Takeover and serve data from the destination bucket (remote cluster)

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrs:

:relative_path: ./s3-snapmirror/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If the data in a source bucket becomes unavailable, you can break the SnapMirror relationship to make the destination bucket writable and begin serving data.

About this task

When a takeover operation is performed, source bucket is converted to read-only and original destination bucket is converted to read-write, thereby reversing the S3 SnapMirror relationship.

When the disabled source bucket is available again, S3 SnapMirror automatically resynchronizes the contents of the two buckets. It is not necessary to explicitly resynchronize the relationship, as is required for volume SnapMirror deployments.

The takeover operation must be initiated from the remote cluster.

== System Manager procedure

Failover from the unavailable bucket and begin serving data:

1. Click **Protection > Relationships**, then select **S3 SnapMirror**.
2. Click **⋮**, select **Failover**, then click **Failover**.

== CLI procedure

1. Initiate a failover operation for the destination bucket:

```
snapmirror failover start -destination-path svm_name:/bucket/bucket_name
```

2. Verify the status of the failover operation:

```
snapmirror show -fields status
```

Example

```
dest_cluster::> snapmirror failover start -destination-path
dest_svm1:/bucket/test-bucket-mirror
```

= Restore a bucket from the destination storage VM (remote cluster)
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./s3-snapmirror/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

If data in a source bucket is lost or corrupted, you repopulate your data by restoring from a destination bucket.

About this task

You can restore the destination bucket to an existing bucket or a new bucket. The target bucket for the restore operation must be larger than the destination bucket's logical used space.

If you use an existing bucket, it must be empty when starting a restore operation. Restore does not "roll back" a bucket in time; rather, it populates an empty bucket with its previous contents.

The restore operation must be initiated from the remote cluster.

== System Manager procedure

Restore the back-up data:

1. Click **Protection > Relationships**, then select **S3 SnapMirror**.
2. Click  and then select **Restore**.
3. Under **Source**, select **Existing Bucket** (the default) or **New Bucket**.
 - To restore to an **Existing Bucket** (the default), complete these actions:
 - Select the cluster and storage VM to search for the existing bucket.
 - Select the existing bucket.
 - Copy and paste the contents of the *destination* S3 server CA certificate.
 - To restore to a **New Bucket**, enter the following values:
 - The cluster and storage VM to host the new bucket.
 - The new bucket's name, capacity, and performance service level.
See [Storage service levels](#) for more information.
 - The contents of the *destination* S3 server CA certificate.
4. Under **Destination**, copy and paste the contents of the *source* S3 server CA certificate.
5. Click **Protection > Relationships** to monitor the restore progress.

== CLI procedure

1. If you are restoring to a new bucket, create the new bucket. For more information, see [Create a backup relationship for a new bucket \(cloud target\)](#).
2. Initiate a restore operation for the destination bucket:
`snapmirror restore -source-path svm_name:/bucket/bucket_name -destination -path svm_name:/bucket/bucket_name`

Example

```
dest_cluster::> snapmirror restore -source-path src_vs1:/bucket/test-
bucket -destination-path dest_vs1:/bucket/test-bucket-mirror
```

= Mirror and backup protection on the local cluster

= Create a mirror relationship for a new bucket (local cluster)

:toc: macro

:hardbreaks:

:toplevels: 1

:icons: font

:linkatrs:

:relative_path: ./s3-snapmirror/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

When you create new S3 buckets, you can protect them immediately to an S3 SnapMirror destination on the same cluster. You can mirror data to a bucket in a different storage VM or the same storage VM as the source.

What you'll need

- Requirements for ONTAP versions, licensing, and S3 server configuration have been completed.
- A peering relationship exists between source and destination storage VMs.
- CA Certificates are needed for the source and destination VMs. You can use self-signed CA certificates or certificates signed by an external CA vendor.

== System Manager procedure

1. If this is the first S3 SnapMirror relationship for this storage VM, verify that root user keys exist for both source and destination storage VMs and regenerate them if they do not:
 - a. Click **Storage > Storage VMs** and then select the storage VM.
 - b. In the **Settings** tab, click  in the S3 tile.
 - c. In the **Users** tab, verify that there is an access key for the root user
 - d. If there is not, click  next to **root**, then click **Regenerate Key**.
Do not regenerate the key if one already exists.
2. Edit the storage VM to add users, and to add users to groups, in both the source and destination storage VMs:
Click **Storage > storage VMs**, click the storage VM, click **Settings** and then click  under S3.
See [Add S3 users and groups](#) for more information.
3. Create an S3 SnapMirror policy if you don't have an existing one and you don't want to use the default policy:
 - a. Click **Protection > Overview**, and then click **Local Policy Settings**.
 - b. Click  next to **Protection Policies**, then click **Add**.
 - Enter the policy name and description.
 - Select the policy scope, cluster or SVM

- Select **Continuous** for S3 SnapMirror relationships.
 - Enter your **Throttle** and **Recovery Point Objective** values.
4. Create a bucket with SnapMirror protection:
- a. Click **Storage > Buckets** then click **Add**.
 - b. Enter a name, select the storage VM, enter a size, then click **More Options**.
 - c. Under **Permissions**, click **Add**. Verifying permissions is optional but recommended.

- **Principal** and **Effect** - select values corresponding to your user group settings, or accept the defaults.

- **Actions** - make sure the following values are shown:

`GetObject, PutObject, DeleteObject, ListBucket, GetBucketAcl, GetObjectAcl
, ListBucketMultipartUploads, ListMultipartUploadParts`

- **Resources** - use the defaults (bucketname, bucketname/*) or other values you need

See [Manage user access to buckets](#) for more information about these fields.

- d. Under **Protection**, check **Enable SnapMirror (ONTAP or Cloud)**. Then enter the following values:

- Destination
 - **TARGET**: ONTAP System
 - **CLUSTER**: Select the remote cluster.
 - **STORAGE VM**: Select a storage VM on the remote cluster.
 - **S3 SERVER CA CERTIFICATE**: Copy and paste the contents of the source certificate.
- Source
 - **S3 SERVER CA CERTIFICATE**: Copy and paste the contents of the destination certificate.

Check **Use the same certificate on the destination** if you are using a certificate signed by an external CA vendor.

If you click **Destination Settings**, you can also enter your own values in place of the defaults for bucket name, capacity, and performance service level.

When you click **Save**, a new bucket is created in the source storage VM, and it is mirrored to a new bucket that is created the destination storage VM.

== CLI procedure

1. If this is the first S3 SnapMirror relationship for this SVM, verify that root user keys exist for both source and destination SVMs and regenerate them if they do not:

```
vserver object-store-server user show
```

Verify that there is an access key for the root user. If there is not, enter:

```
vserver object-store-server user regenerate-keys -vserver svm_name -user root
```

Do not regenerate the key if one already exists.

2. Create buckets in both the source and destination SVMs:

```
vserver object-store-server bucket create -vserver svm_name -bucket  
bucket_name [-size integer[KB|MB|GB|TB|PB]] [-comment text]  
[additional_options]
```

3. Add access rules to the default bucket policies in both the source and destination SVMs:

```
vserver object-store-server bucket policy add-statement -vserver svm_name  
-bucket bucket_name -effect {allow|deny} -action object_store_actions  
-principal user_and_group_names -resource object_store_resources [-sid  
text] [-index integer]
```

Example

```
src_cluster::> vserver object-store-server bucket policy add-  
statement -bucket test-bucket -effect allow -action  
GetObject,PutObject,DeleteObject,ListBucket,GetBucketAcl,GetObjectAc  
l,ListBucketMultipartUploads,ListMultipartUploadParts -principal -  
resource test-bucket, test-bucket /*
```

4. Create an S3 SnapMirror policy if you don't have an existing one and you don't want to use the default policy:

```
snapmirror policy create -vserver svm_name -policy policy_name -type  
continuous [-rpo integer] [-throttle throttle_type] [-comment text]  
[additional_options]
```

Parameters:

- continuous – the only policy type for S3 SnapMirror relationships (required).
- -rpo – specifies the time for recovery point objective, in seconds (optional).
- -throttle – specifies the upper limit on throughput/bandwidth, in kilobytes/seconds (optional).

Example

```
src_cluster::> snapmirror policy create -vserver vs0 -type  
continuous -rpo 0 -policy test-policy
```

5. Install CA server certificates on the admin SVM:

- a. Install the CA certificate that signed the *source* S3 server's certificate on the admin SVM:

```
security certificate install -type server-ca -vserver admin_svm -cert  
-name src_server_certificate
```

- b. Install the CA certificate that signed the *destination* S3 server's certificate on the admin SVM:

```
security certificate install -type server-ca -vserver admin_svm -cert  
-name dest_server_certificate
```

If you are using a certificate signed by an external CA vendor, you only need to install this certificate on the admin SVM.

See the security certificate install man page for details.

6. Create an S3 SnapMirror relationship:

```
snapmirror create -source-path src_svm_name:/bucket/bucket_name  
-destination-path dest_peer_svm_name:/bucket/bucket_name, ...} [-policy  
policy_name]
```

You can use a policy you created or accept the default.

Example

```
src_cluster::> snapmirror create -source-path vs0-src:/bucket/test-  
bucket -destination-path vs1-dest:/vs1/bucket/test-bucket-mirror  
-policy test-policy
```

7. Verify that mirroring is active:

```
snapmirror show -policy-type continuous -fields status
```

= Create a mirror relationship for an existing bucket (local cluster)

:toc: macro

:hardbreaks:

:toplevels: 1

:icons: font

:linkatrrs:

:relative_path: ./s3-snapmirror/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can begin protecting existing S3 buckets on the same cluster at any time; for example, if you upgraded an S3 configuration from a release earlier than ONTAP 9.10.1. You can mirror data to a bucket in a different storage VM or the same storage VM as the source.

What you'll need

- Requirements for ONTAP versions, licensing, and S3 server configuration have been completed.
- A peering relationship exists between source and destination storage VMs.
- CA Certificates are needed for the source and destination VMs. You can use self-signed CA certificates or certificates signed by an external CA vendor.

== System Manager procedure

1. If this is the first S3 SnapMirror relationship for this storage VM, verify that root user keys exist for both source and destination storage VMs and regenerate them if they do not:
 - a. Click **Storage > Storage VMs** and then select the storage VM.
 - b. In the **Settings** tab, click  in the **S3** tile.
 - c. In the **Users** tab, verify that there is an access key for the root user.
 - d. If there is not, click  next to **root**, then click **Regenerate Key**.
Do not regenerate the key if one already exists
2. Verify that user and group access is correct in both the source and destination storage VMs:

- Click **Storage > storage VMs**, click the storage VM, click **Settings** and then click  under S3.

See [Add S3 users and groups](#) for more information.

3. Create an S3 SnapMirror policy if you don't have an existing one and you don't want to use the default policy:

- a. Click **Protection > Overview**, and then click **Local Policy Setting**.

- b. Click  next to **Protection Policies**, then click **Add**.

- Enter the policy name and description.
- Select the policy scope, cluster or SVM
- Select **Continuous** for S3 Snapmirror relationships.
- Enter your **Throttle** and **Recovery Point Objective** values.

4. Verify that the bucket access policy of the existing bucket continues to meet your needs:

- a. Click **Storage > Buckets** and then select the bucket you want to protect.

- b. In the **Permissions** tab, click  **Edit**, then click **Add** under **Permissions**.

- **Principal** and **Effect** - select values corresponding to your user group settings, or accept the defaults.
- **Actions** - make sure the following values are shown:
`GetObject,PutObject,DeleteObject,ListBucket,GetBucketAcl,GetObjectAcl, ListBucketMultipartUploads, ListMultipartUploadParts`
- **Resources** - use the defaults (`bucketname, bucketname/*`) or other values you need.

See [Manage user access to buckets](#) for more information about these fields.

5. Protect an existing bucket with S3 SnapMirror:

- a. Click **Storage > Buckets** and then select the bucket you want to protect.

- b. Click **Protect** and enter the following values:

- Destination
 - **TARGET**: ONTAP System
 - **CLUSTER**: Select the local cluster.
 - **STORAGE VM**: Select the same or a different storage VM.
 - **S3 SERVER CA CERTIFICATE**: Copy and paste the contents of the *source* certificate.
- Source
 - **S3 SERVER CA CERTIFICATE**: Copy and paste the contents of the *destination* certificate.

Check **Use the same certificate on the destination** if you are using a certificate signed by an external CA vendor.

If you click **Destination Settings**, you can also enter your own values in place of the defaults for bucket name, capacity, and performance service level.

When you click **Save**, the existing bucket is mirrored to a new bucket in the destination storage VM.

== CLI procedure

1. If this is the first S3 SnapMirror relationship for this SVM, verify that root user keys exist for both source and destination SVMs and regenerate them if they do not:

```
vserver object-store-server user show
```

Verify that there is an access key for the root user. If there is not, enter:

```
vserver object-store-server user regenerate-keys -vserver svm_name -user root
```

Do not regenerate the key if one already exists.

2. Create a bucket on the destination SVM to be the mirror target:

```
vserver object-store-server bucket create -vserver svm_name -bucket dest_bucket_name [-size integer[KB|MB|GB|TB|PB]] [-comment text] [additional_options]
```

3. Verify that the access rules to the default bucket policies are correct in both the source and destination SVMs:

```
vserver object-store-server bucket policy add-statement -vserver svm_name -bucket bucket_name -effect {allow|deny} -action object_store_actions -principal user_and_group_names -resource object_store_resources [-sid text] [-index integer] `
```

Example

```
clusterA::> vserver object-store-server bucket policy add-statement -bucket test-bucket -effect allow -action GetObject,PutObject,DeleteObject,ListBucket,GetBucketAcl,GetObjectAcl,ListBucketMultipartUploads,ListMultipartUploadParts -principal -resource test-bucket, test-bucket /*
```

4. Create an S3 SnapMirror policy if you don't have an existing one and you don't want to use the default policy:

```
snapmirror policy create -vserver svm_name -policy policy_name -type continuous [-rpo _integer] [-throttle throttle_type] [-comment text] [additional_options]
```

Parameters:

- continuous – the only policy type for S3 SnapMirror relationships (required).
- -rpo – specifies the time for recovery point objective, in seconds (optional).
- -throttle – specifies the upper limit on throughput/bandwidth, in kilobytes/seconds (optional).

Example

```
clusterA::> snapmirror policy create -vserver vs0 -type continuous -rpo 0 -policy test-policy
```

5. Install CA server certificates on the admin SVM:

- Install the CA certificate that signed the *source* S3 server's certificate on the admin SVM:

```
security certificate install -type server-ca -vserver admin_svm -cert  
-name src_server_certificate
```

- Install the CA certificate that signed the *destination* S3 server's certificate on the admin SVM:

```
security certificate install -type server-ca -vserver admin_svm -cert  
-name dest_server_certificate
```

If you are using a certificate signed by an external CA vendor, you only need to install this certificate on the admin SVM.

See the `security certificate install` man page for details.

6. Create an S3 SnapMirror relationship:

```
snapmirror create -source-path src_svm_name:/bucket/bucket_name  
-destination-path dest_peer_svm_name:/bucket/bucket_name, ...} [-policy  
policy_name]
```

You can use a policy you created or accept the default.

Example

```
src_cluster::> snapmirror create -source-path vs0-src:/bucket/test-  
bucket -destination-path vs1-dest:/bucket/test-bucket-mirror -policy  
test-policy
```

7. Verify that mirroring is active:

```
snapmirror show -policy-type continuous -fields status
```

= Takeover and serve data from the destination bucket (local cluster)

:toc: macro

:hardbreaks:

:toplevels: 1

:icons: font

:linkatrrs:

:relative_path: ./s3-snapmirror/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..../media/

If the data in a source bucket becomes unavailable, you can break the SnapMirror relationship to make the destination bucket writable and begin serving data.

About this task

When a takeover operation is performed, source bucket is converted to read-only and original destination bucket is converted to read-write, thereby reversing the S3 SnapMirror relationship.

When the disabled source bucket is available again, S3 SnapMirror automatically resynchronizes the contents of the two buckets. You don't need to explicitly resynchronize the relationship, as is required for standard volume SnapMirror deployments.

If the destination bucket is on a remote cluster, the takeover operation must be initiated from the remote cluster.

== System Manager procedure

Failover from the unavailable bucket and begin serving data:

1. Click **Protection > Relationships**, then select **S3 SnapMirror**.
2. Click , select **Failover**, then click **Failover**.

== CLI procedure

1. Initiate a failover operation for the destination bucket:

```
snapmirror failover start -destination-path svm_name:/bucket/bucket_name
```

2. Verify the status of the failover operation:

```
snapmirror show -fields status
```

Example

```
clusterA::> snapmirror failover start -destination-path vs1:/bucket/test-bucket-mirror
```

= Restore a bucket from the destination storage VM (remote cluster)

:toc: macro

:hardbreaks:

:toclevels: 1

:icons: font

:linkatrrs:

:relative_path: ./s3-snapmirror/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

When data in a source bucket is lost or corrupted, you repopulate your data by restoring from a destination bucket.

About this task

You can restore the destination bucket to an existing bucket or a new bucket. The target bucket for the restore operation must be larger than the destination bucket's logical used space.

If you use an existing bucket, it must be empty when starting a restore operation. Restore does not "roll back" a bucket in time; rather, it populates an empty bucket with its previous contents.

The restore operation must be initiated from the remote cluster.

== System Manager procedure

Restore the back-up data:

1. Click **Protection > Relationships**, then select the bucket.
2. Click and then select **Restore**.
3. Under **Source**, select **Existing Bucket** (the default) or **New Bucket**.
 - To restore to an **Existing Bucket** (the default), complete these actions:
 - Select the cluster and storage VM to search for the existing bucket.
 - Select the existing bucket.
4. Copy and paste the contents of the destination S3 server CA certificate.

- To restore to a **New Bucket**, enter the following values:
 - The cluster and storage VM to host the new bucket.
 - The new bucket's name, capacity, and performance service level. See [Storage service levels](#) for more information.
 - The contents of the destination S3 server CA certificate.
5. Under **Destination**, copy and paste the contents of the source S3 server CA certificate.
 6. Click **Protection** > Relationships to monitor the restore progress.

== CLI procedure

1. If you are restoring to a new bucket, create the new bucket. For more information, see [Create a backup relationship for a new bucket \(cloud target\)](#).
2. Initiate a restore operation for the destination bucket:

```
snapmirror restore -source-path svm_name:/bucket/bucket_name -destination
-path svm_name:/bucket/bucket_name
```

Example

```
clusterA::> snapmirror restore -source-path vs0:/bucket/test-bucket
-destination-path vs1:/bucket/test-bucket-mirror
```

= Backup protection with cloud targets

= Requirements for cloud target relationships
:toc: macro
:hardbreaks:
:toclevels: 1
:icons: font
:linkatrrs:
:relative_path: ./s3-snapmirror/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Make sure that your source and target environments meet the requirements for S3 SnapMirror backup protection to cloud targets.

You must have valid account credentials with the object store provider to access the data bucket.

Intercluster network interfaces and an IPspace should be configured on the cluster before the cluster can connect to a cloud object store. You should create enter cluster network interfaces on each node to seamlessly transfer data from the local storage to the cloud object store.

For StorageGRID targets, you need to know the following information:

- server name, expressed as a fully-qualified domain name (FQDN) or IP address
- bucket name; the bucket must already exist
- access key
- secret key

In addition, the CA certificate used to sign the StorageGRID server certificate needs to be installed on the

ONTAP S3 cluster's admin storage VM using the `security certificate install` command. For more information, see [Installing a CA certificate](#) if you use StorageGRID.

For AWS S3 targets, you need to know the following information:

- server name, expressed as a fully-qualified domain name (FQDN) or IP address
- bucket name; the bucket must already exist
- access key
- secret key

The DNS server for the ONTAP cluster's admin storage VM must be able to resolve FQDNs (if used) to IP addresses.

= Create a backup relationship for a new bucket (cloud target)

:toc: macro

:hardbreaks:

:toclevels: 1

:icons: font

:linkattrs:

:relative_path: ./s3-snapmirror/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

When you create new S3 buckets, you can back them up immediately to an S3 SnapMirror target bucket on an object store provider, which can be a StorageGRID system or an AWS S3 deployment.

What you'll need

- You have valid account credentials and configuration information for the object store provider.
- Intercluster network interfaces and an IPspace have been configured on the source system.
- • The DNS configuration for the source storage VM must be able to resolve the target's FQDN.

== System Manager procedure

1. Edit the storage VM to add users, and to add users to groups:

- a. Click **Storage > storage VMs**, click the storage VM, click **Settings** and then click  under **S3**.

See [Add S3 users and groups](#) for more information.

2. Add a Cloud Object Store on the source system:

- a. Click **Protection > Overview**, then select **Cloud Object Stores**.

- b. Click **Add**, then select **Amazon S3 or StorageGRID**.

- c. Enter the following values:

- Cloud object store name
- URL style (path or virtual-hosted)
- storage VM (enabled for S3)
- Object store server name (FQDN)
- Object store certificate

- Access key
- Secret key
- Container (bucket) name

3. Create an S3 SnapMirror policy if you don't have an existing one and you don't want to use the default policy:

a. Click **Protection > Overview**, and then click **Local Policy Settings**.

b. Click  next to **Protection Policies**, then click **Add**.

- Enter the policy name and description.
- Select the policy scope, cluster or SVM
- Select **Continuous** for S3 SnapMirror relationships.
- Enter your **Throttle** and **Recovery Point Objective** values.

4. Create a bucket with SnapMirror protection:

a. Click **Storage > Buckets**, then click **Add**.

b. Enter a name, select the storage VM, enter a size, then click **More Options**.

c. Under **Permissions**, click **Add**. Verifying permissions is optional but recommended.

- **Principal** and **Effect** - select values corresponding to your user group settings or accept the defaults.
- **Actions** - make sure the following values are shown:
GetObject, PutObject, DeleteObject, ListBucket, GetBucketAcl, GetObjectAcl
, ListBucketMultipartUploads, ListMultipartUploadParts
- **Resources** - use the defaults `_ (bucketname, bucketname/*)` or other values you need.

See [Manage user access to buckets](#) for more information about these fields.

d. Under **Protection**, check **Enable SnapMirror (ONTAP or Cloud)**, select **Cloud Storage**, then select the **Cloud Object Store**.

When you click **Save**, a new bucket is created in the source storage VM, and it is backed up to the cloud object store.

== CLI procedure

1. If this is the first S3 SnapMirror relationship for this SVM, verify that root user keys exist for both source and destination SVMs and regenerate them if they do not:

```
vserver object-store-server user show
```

Confirm that there is an access key for the root user. If there is not, enter:

```
vserver object-store-server user regenerate-keys -vserver svm_name -user root
```

Do not regenerate the key if one already exists.

2. Create a bucket in the source SVM:

```
vserver object-store-server bucket create -vserver svm_name -bucket bucket_name [-size integer[KB|MB|GB|TB|PB]] [-comment text] [additional_options]
```

3. Add access rules to the default bucket policy:

```
vserver object-store-server bucket policy add-statement -vserver svm_name -bucket bucket_name -effect {allow|deny} -action object_store_actions -principal user_and_group_names -resource object_store_resources [-sid text] [-index integer]
```

Example

```
clusterA::> vserver object-store-server bucket policy add-statement -bucket test-bucket -effect allow -action GetObject,PutObject,DeleteObject,ListBucket,GetBucketAcl,GetObjectAcl,ListBucketMultipartUploads,ListMultipartUploadParts -principal -resource test-bucket, test-bucket /*
```

4. Create an S3 SnapMirror policy if you don't have an existing one and you don't want to use the default policy:

```
snapmirror policy create -vserver svm_name -policy policy_name -type continuous [-rpo integer] [-throttle throttle_type] [-comment text] [additional_options]
```

Parameters:

- * *type continuous* – the only policy type for S3 SnapMirror relationships (required).
- * *-rpo* – specifies the time for recovery point objective, in seconds (optional).
- * *-throttle* – specifies the upper limit on throughput/bandwidth, in kilobytes/seconds (optional).

Example

```
clusterA::> snapmirror policy create -vserver vs0 -type continuous -rpo 0 -policy test-policy
```

5. If the target is a StorageGRID system, install the StorageGRID CA server certificate on the admin SVM of the source cluster:

```
security certificate install -type server-ca -vserver src_admin_svm -cert -name storage_grid_server_certificate
```

See the `security certificate install` man page for details.

6. Define the S3 SnapMirror destination object store:

```
snapmirror object-store config create -vserver svm_name -object-store-name target_store_name -usage data -provider-type {AWS_S3|SGWS} -server target_FQDN -container-name remote_bucket_name -is-ssl-enabled true -port port_number -access-key target_access_key -secret-password target_secret_key
```

Parameters:

- * *-object-store-name* – the name of the object store target on the local ONTAP system.
- * *-usage* – use data for this workflow.
- * *-provider-type* – AWS_S3 and SGWS (StorageGRID) targets are supported.
- * *-server* – the target server's FQDN or IP address.
- * *-is-ssl-enabled* – enabling SSL is optional but recommended.

See the snapmirror object-store config create man page for details.

Example

```
src_cluster::> snapmirror object-store config create -vserver vs0  
-object-store-name sgws-store -usage data -provider-type SGWS  
-server sgws.example.com -container-name target-test-bucket -is-ssl  
-enabled true -port 443 -access-key abc123 -secret-password xyz890
```

7. Create an S3 SnapMirror relationship:

```
snapmirror create -source-path svm_name:/bucket/bucket_name -destination  
-path object_store_name:/objstore -policy policy_name
```

Parameters:

* -destination-path – the object store name you created in the previous step and the fixed value objstore.

You can use a policy you created or accept the default.

Example

```
src_cluster::> snapmirror create -source-path vs0:/bucket/test-  
bucket -destination-path sgws-store:/objstore -policy test-policy
```

8. Verify that mirroring is active:

```
snapmirror show -policy-type continuous -fields status
```

= Create a backup relationship for an existing bucket (cloud target)

:toc: macro

:linkatrrs:

:relative_path: ./s3-snapmirror/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can begin backing up existing S3 buckets at any time; for example, if you upgraded an S3 configuration from a release earlier than ONTAP 9.10.1.

What you'll need

- You have valid account credentials and configuration information for the object store provider.
- Intercluster network interfaces and an IPspace have been configured on the source system.
- The DNS configuration for the source storage VM must be able to resolve the target's FQDN.

== System Manager procedure

1. Verify that the users and groups are correctly defined:

Click **Storage > storage VMs**, click the storage VM, click **Settings** and then click  under S3.

See [Add S3 users and groups](#) for more information.

2. Create an S3 SnapMirror policy if you don't have an existing one and you don't want to use the default policy:
 - a. Click **Protection > Overview**, and then click **Local Policy Settings**.
 - b. Click  next to **Protection Policies**, then click **Add**.
 - c. Enter the policy name and description.
 - d. Select the policy scope, cluster or SVM
 - e. Select **Continuous** for S3 SnapMirror relationships.
 - f. Enter your **Throttle** and **Recovery Point Objective values**.
3. Add a Cloud Object Store on the source system:
 - a. Click **Protection > Overview**, then select **Cloud Object Store**.
 - b. Click **Add**, then select **Amazon S3 or Others** for StorageGRID Webscale.
 - c. Enter the following values:
 - Cloud object store name
 - URL style (path or virtual-hosted)
 - storage VM (enabled for S3)
 - Object store server name (FQDN)
 - Object store certificate
 - Access key
 - Secret key
 - Container (bucket) name
4. Verify that the bucket access policy of the existing bucket still meets your needs:
 - a. Click **Storage > Buckets** and then select the bucket you want to protect.
 - b. In the **Permissions** tab, click  **Edit**, then click **Add** under **Permissions**.
 - **Principal** and **Effect** - select values corresponding to your user group settings or accept the defaults.
 - **Actions** - make sure the following values are shown:
`GetObject,PutObject,DeleteObject,ListBucket,GetBucketAcl,GetObjectAcl, ListBucketMultipartUploads, ListMultipartUploadParts`
 - **Resources** - use the defaults (`bucketname, bucketname/*`) or other values you need.
5. Back up the bucket using S3 SnapMirror:
 - a. Click **Storage > Buckets** and then select the bucket you want to back up.
 - b. Click **Protect**, select **Cloud Storage** under **Target**, then select the **Cloud Object Store**.

When you click **Save**, the existing bucket is backed up to the cloud object store.

== CLI procedure

1. Verify that the access rules in the default bucket policy are correct:

```
vserver object-store-server bucket policy add-statement -vserver svm_name -bucket bucket_name -effect {allow|deny} -action object_store_actions -principal user_and_group_names -resource object_store_resources [-sid text] [-index integer]
```

Example

```
clusterA::> vserver object-store-server bucket policy add-statement -bucket test-bucket -effect allow -action GetObject,PutObject,DeleteObject,ListBucket,GetBucketAcl,GetObjectAcl,ListBucketMultipartUploads,ListMultipartUploadParts -principal -resource test-bucket, test-bucket /*
```

2. Create an S3 SnapMirror policy if you don't have an existing one and you don't want to use the default policy:

```
snapmirror policy create -vserver svm_name -policy policy_name -type continuous [-rpo integer] [-throttle throttle_type] [-comment text] [additional_options]
```

Parameters:

- * *type continuous* – the only policy type for S3 SnapMirror relationships (required).
- * *-rpo* – specifies the time for recovery point objective, in seconds (optional).
- * *-throttle* – specifies the upper limit on throughput/bandwidth, in kilobytes/seconds (optional).

Example

```
clusterA::> snapmirror policy create -vserver vs0 -type continuous -rpo 0 -policy test-policy
```

3. If the target is a StorageGRID system, install the StorageGRID CA certificate on the admin SVM of the source cluster:

```
security certificate install -type server-ca -vserver src_admin_svm -cert -name storage_grid_server_certificate
```

See the `security certificate install` man page for details.

4. Define the S3 SnapMirror destination object store:

```
snapmirror object-store config create -vserver svm_name -object-store-name target_store_name -usage data -provider-type {AWS_S3|SGWS} -server target_FQDN -container-name remote_bucket_name -is-ssl-enabled true -port port_number -access-key target_access_key -secret-password target_secret_key
```

Parameters:

- * *-object-store-name* – the name of the object store target on the local ONTAP system.
- * *-usage* – use data for this workflow.
- * *-provider-type* – AWS_S3 and SGWS (StorageGRID) targets are supported.
- * *-server* – the target server's FQDN or IP address.
- * *-is-ssl-enabled* – enabling SSL is optional but recommended.

See the snapmirror object-store config create man page for details.

Example

```
src_cluster::> snapmirror object-store config create -vserver vs0  
-object-store-name sgws-store -usage data -provider-type SGWS  
-server sgws.example.com -container-name target-test-bucket -is-ssl  
-enabled true -port 443 -access-key abc123 -secret-password xyz890
```

5. Create an S3 SnapMirror relationship:

```
snapmirror create -source-path svm_name:/bucket/bucket_name -destination  
-path object_store_name:/objstore -policy policy_name
```

Parameters:

* -destination-path – the object store name you created in the previous step and the fixed value objstore.

You can use a policy you created or accept the default.

Example

```
src_cluster::> snapmirror create -source-path vs0:/bucket/buck-evp  
-destination-path sgws-store:/objstore -policy test-policy
```

6. Verify that mirroring is active:

```
snapmirror show -policy-type continuous -fields status
```

= Restore a bucket from a cloud target

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./s3-snapmirror/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

When data in a source bucket is lost or corrupted, you repopulate your data by restoring from a destination bucket.

About this task

You can restore the destination bucket to an existing bucket or a new bucket. The target bucket for the restore operation must be larger than the destination bucket's logical used space.

If you use an existing bucket, it must be empty when starting a restore operation. Restore does not "roll back" a bucket in time; rather, it populates an empty bucket with its previous contents.

-- System Manager procedure

Restore the back-up data:

1. Click **Protection > Relationships**, then select **S3 SnapMirror**.
2. Click and then select **Restore**.
3. Under **Source**, select **Existing Bucket** (the default) or **New Bucket**.
 - To restore to an **Existing Bucket** (the default), complete these actions:
 - Select the cluster and storage VM to search for the existing bucket.
 - Select the existing bucket.
 - Copy and paste the contents of the *destination* S3 server CA certificate.
 - To restore to a **New Bucket**, enter the following values:
 - The cluster and storage VM to host the new bucket.
 - The new bucket's name, capacity, and performance service level.
See [Storage service levels](#) for more information.
 - The contents of the destination S3 server CA certificate.
4. Under **Destination**, copy and paste the contents of the *source* S3 server CA certificate.
5. Click **Protection > Relationships** to monitor the restore progress.

== CLI procedure

. If you are restoring to a new bucket, create the new bucket. For more information, see [Create a backup relationship for a bucket \(cloud target\)](#).

. Initiate a restore operation for the destination bucket:

```
snapmirror restore -source-path object_store_name:/objstore -destination-path
svm_name:/bucket/bucket_name
```

+

.Example

+

The following example restores a destination bucket to an existing bucket.

```
clusterA::> snapmirror restore -source-path sgws.store:/objstore -destination
-path vs0:/bucket/test-bucket
```

= Modify a mirror policy

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrs:

:relative_path: ./s3-snapmirror/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You might want to modify an S3 mirror policy; for example, if you want to adjust the RPO and throttle values.

== System Manager procedure

If you want to adjust these values, you can edit an existing protection policy.

1. Click **Protection > Relationships**, and then select the protection policy for the relationship you want to modify.

2. Click  next to the policy name, then click **Edit**.

== CLI procedure

Modify an S3 SnapMirror policy:

```
snapmirror policy modify -vserver svm_name -policy policy_name [-rpo integer]  
[-throttle throttle_type] [-comment text]
```

Parameters:

- **-rpo** – specifies the time for recovery point objective, in seconds.
- **-throttle** – specifies the upper limit on throughput/bandwidth, in kilobytes/seconds.

Example

```
clusterA::> snapmirror policy modify -vserver vs0 -policy test-policy  
-rpo 60
```

= Audit S3 events

= Audit S3 events

:icons: font

:relative_path: ./s3-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

Beginning with ONTAP 9.10.1, you can audit data and management events in ONTAP S3 environments. S3 audit functionality is similar to existing NAS auditing capabilities, and S3 and NAS auditing can coexist in a cluster.

When you create and enable an S3 auditing configuration on an SVM, S3 events are recorded in a log file. The you can specify the following events to be logged:

- Object access (data) events
 - GetObject, PutObject, and DeleteObject
- Management events
 - PutBucket and DeleteBucket

The log format is JavaScript Object Notation (JSON).

The combined limit for S3 and NFS auditing configurations is 50 SVMs per cluster.

The following license bundle is required:

* Core Bundle, for ONTAP S3 protocol and storage

For more information, see [How the ONTAP auditing process works](#).

== Guaranteed auditing

By default, S3 and NAS auditing is guaranteed. ONTAP guarantees that all auditable bucket access events are recorded, even if a node is unavailable. A requested bucket operation cannot be completed

until the audit record for that operation is saved to the staging volume on persistent storage. If audit records cannot be committed in the staging files, either because of insufficient space or because of other issues, client operations are denied.

== Space requirements for auditing

In the ONTAP auditing system, audit records are initially stored in binary staging files on individual nodes. Periodically, they are consolidated and converted to user-readable event logs, which are stored in the audit event log directory for the SVM.

The staging files are stored in a dedicated staging volume, which is created by ONTAP when the auditing configuration is created. There is one staging volume per aggregate.

You must plan for sufficient available space in the auditing configuration:

- For the staging volumes in aggregates that contain audited buckets.
- For the volume containing the directory where converted event logs are stored.

You can control the number of event logs, and hence the available space in the volume, using one of two methods when creating the S3 auditing configuration:

- A numerical limit; the `-rotate-limit` parameter controls the minimum number of audit files that must be preserved.
- A time limit; the `-retention-duration` parameter controls the maximum period that files can be preserved.

In both parameters, once that configured is exceeded, older audit files can be deleted to make room for newer ones. For both parameters, the value is 0, indicating that all files must be maintained. In order to ensure sufficient space, it is therefore a best practice to set one of the parameters to a non-zero value.

Because of guaranteed auditing, if the space available for audit data runs out before the rotation limit, newer audit data cannot be created, resulting in failure to clients accessing data. Therefore, the choice of this value and of the space allocated to auditing must be chosen carefully, and you must respond to warnings about available space from the auditing system.

For more information, see [Basic auditing concepts](#).

= Plan an S3 auditing configuration

You must specify a number of parameters for the S3 auditing configuration or accept the defaults. In particular, you should consider which log rotation parameters will help ensure adequate free space.

See the **vserver object-store-server audit create** man page for syntax details.

== General parameters

There are two required parameters that you must specify when you create the auditing configuration. There are also three optional parameters that you can specify.

Type of information	Option	Required
<p><i>SVM name</i></p> <p>Name of the SVM on which to create the auditing configuration.</p> <p>The SVM must already exist and be enabled for S3.</p>	<code>-verserver svm_name</code>	Yes
<p><i>Log destination path</i></p> <p>Specifies where the converted audit logs are stored. The path must already exist on the SVM.</p> <p>The path can be up to 864 characters in length and must have read-write permissions.</p> <p>If the path is not valid, the audit configuration command fails.</p>	<code>-destination text</code>	Yes
<p><i>Categories of events to audit</i></p> <p>The following event categories can be audited:</p> <ul style="list-style-type: none"> * data GetObject, PutObject, and DeleteObject events * management PutBucket and DeleteBucket events <p>The default is to audit data events only.</p>	<code>-events {data management}, ...</code>	No

You can enter one of the following parameters to control the number of audit log files. If no value is entered, all log files are retained.

Type of information	Option	Required
<p><i>Log files rotation limit</i></p> <p>Determines how many audit log files to retain before rotating the oldest log file out. For example, if you enter a value of 5, the last five log files are retained.</p> <p>A value of 0 indicates that all the log files are retained. The default value is 0.</p>	<code>-rotate-limit integer</code>	No
<p><i>Log files duration limit</i></p> <p>Determines how long a log file can be retained before being deleted. For example, if you enter a value of 5d0h0m, logs more than 5 days old are deleted.</p> <p>A value of 0 indicates that all the log files are retained. The default value is 0.</p>	<code>-retention duration integer_time</code>	No

== Parameters for audit log rotation

You can rotate audit logs based on size or schedule. The default is to rotate audit logs based on size.

==== Rotate logs based on log size

If you want to use the default log rotation method and the default log size, you do not need to configure any specific parameters for log rotation. The default log size is 100 MB.

If you do not want to use the default log size, you can configure the **-rotate-size** parameter to specify a custom log size.

If you want to reset the rotation based on a log size alone, use the following command to unset the **-rotate-schedule-minute** parameter:

```
vserver audit modify -vserver svm_name -destination / -rotate-schedule-minute  
-
```

==== Rotate logs based on a schedule

If you choose to rotate the audit logs based on a schedule, you can schedule log rotation by using the time-based rotation parameters in any combination.

- If you use time-based rotation, the **-rotate-schedule-minute** parameter is mandatory.
- All other time-based rotation parameters are optional.
 - **-rotate-schedule-month**
 - **-rotate-schedule-dayofweek**
 - **-rotate-schedule-day**
 - **-rotate-schedule-hour**
- The rotation schedule is calculated by using all the time-related values.
For example, if you specify only the **-rotate-schedule-minute** parameter, the audit log files are rotated based on the minutes specified on all days of the week, during all hours on all months of the year.
- If you specify only one or two time-based rotation parameters (for example, **-rotate-schedule-month** and **-rotate-schedule-minutes**), the log files are rotated based on the minute values that you specified on all days of the week, during all hours, but only during the specified months.

For example, you can specify that the audit log is to be rotated during the months January, March, and August on all Mondays, Wednesdays, and Saturdays at 10:30 a.m.

- If you specify values for both **-rotate-schedule-dayofweek** and **-rotate-schedule-day**, they are considered independently.

For example, if you specify **-rotate-schedule-dayofweek** as Friday and **-rotate-schedule-day** as 13, then the audit logs would be rotated on every Friday and on the 13th day of the specified month, not just on every Friday the 13th.

- If you want to reset the rotation based on a schedule alone, use the following command to unset the **-rotate-size** parameter:

```
vserver audit modify -vserver svm_name -destination / -rotate-size -
```

== Rotate logs based on log size and schedule

You can choose to rotate the log files based on log size and a schedule by setting both the `-rotate-size` parameter and the time-based rotation parameters in any combination. For example: if `-rotate-size` is set to 10 MB and `-rotate-schedule-minute` is set to 15, the log files rotate when the log file size reaches 10 MB or on the 15th minute of every hour (whichever event occurs first).

= Create and enable an S3 auditing configuration

To implement S3 auditing, you first create a persistent object store auditing configuration on an S3-enabled SVM, then enable the configuration.

What you'll need

- An S3-enabled SVM.
- Sufficient space for staging volumes in the aggregate.

About this task

An auditing configuration is required for each SVM that contains S3 buckets that you wish to audit. You can enable S3 auditing on new or existing S3 servers. Auditing configurations persist in an S3 environment until removed by the **vserver object-store-server audit delete** command.

The S3 auditing configuration applies to all buckets in the SVM that you select for auditing. An audit-enabled SVM can contain audited and un-audited buckets.

It is recommended that you configure S3 auditing for automatic log rotation, determined by log size or a schedule. If you don't configure automatic log rotation, all log files are retained by default. You can also rotate S3 log files manually using the **vserver object-store-server audit rotate-log** command.

If the SVM is an SVM disaster recovery source, the destination path cannot be on the root volume.

Procedure

1. Create the auditing configuration to rotate audit logs based on log size or a schedule.

If you want to rotate audit logs by...	Enter...
Log size	<pre>vserver object-store-server audit create -vserver svm_name -destination path [[-events] {data management}, ...] {[-rotate-limit integer] [-retention-duration [integer_d] [_integer_h][_integer_m][_integers]]} [-rotate- size {integer[KB MB GB TB PB]}]</pre>

If you want to rotate audit logs by...	Enter...
A schedule	<pre>vserver object-store-server audit create -vserver svm_name -destination path [[-events] {data management}, ...] {[-rotate-limit integer] [-retention-duration [integerd] [integerh] [integerm] [integers]]} [-rotate-schedule-month chron_month] [-rotate-schedule-dayofweek chron_dayofweek] [-rotate-schedule-day chron_dayofmonth] [-rotate-schedule-hour chron_hour] -rotate-schedule-minute chron_minute</pre> <p>The <code>-rotate-schedule-minute</code> parameter is required if you are configuring time-based audit log rotation.</p>

2. Enable S3 auditing:

```
vserver object-store-server audit enable -vserver svm_name
```

Examples

The following example creates an auditing configuration that audits all S3 events (the default) using size-based rotation. The logs are stored in the `/audit_log` directory. The log file size limit is 200 MB. The logs are rotated when they reach 200 MB in size.

```
cluster1::> vserver audit create -vserver vs1 -destination /audit_log -rotate
-size 200MB
```

The following example creates an auditing configuration that audits all S3 events (the default) using size-based rotation. The log file size limit is 100 MB (the default), and the logs are retained for 5 days before being deleted.

```
cluster1::> vserver audit create -vserver vs1 -destination /audit_log
-retention-duration 5d0h0m
```

The following example creates an auditing configuration that audits S3 management events, and central access policy staging events using time-based rotation. The audit logs are rotated monthly, at 12:30 p.m. on all days of the week. The log rotation limit is 5.

```
cluster1::> vserver audit create -vserver vs1 -destination /audit_log -events
management -rotate-schedule-month all -rotate-schedule-dayofweek all -rotate
-schedule-hour 12 -rotate-schedule-minute 30 -rotate-limit 5
```

= Select buckets for S3 auditing

:icons: font

:relative_path: ./s3-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You must specify which buckets to audit in an audit-enabled SVM.

What you'll need

- An SVM enabled for S3 auditing.

About this task

S3 auditing configurations are enabled on a per-SVM basis, but you must select the buckets in SVMS that are enabled for audit. If you add buckets to the SVM and you want the new buckets to be audited, you must select them with this procedure. You can also have non-audited buckets in an SVM enabled for S3 auditing.

Auditing configurations persist for buckets until removed by the `vserver object-store-server audit object-select delete` command.

Procedure

Select a bucket for S3 auditing:

```
vserver object-store-server audit event-selector create -vserver svm_name
-bucket bucket_name [[-access] {read-only|write-only|all}] [[-permission]
{allow-only|deny-only|all}]
```

- `-access` - specifies the type of event access to be audited: `read-only`, `write-only` or `all` (default is `all`).
- `-permission` - specifies the type of event permission to be audited: `allow-only`, `deny-only` or `all` (default is `all`).

Example

The following example creates a bucket auditing configuration that only logs allowed events with read-only access:

```
cluster1::> vserver object-store-server audit event-selector create -vserver
vs1 -bucket test-bucket -access read-only -permission allow-only
```

= Modify an S3 auditing configuration
:icons: font
:relative_path: ./s3-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin/..media/

You can modify the auditing parameters of individual buckets or the auditing configuration of all buckets selected for audit in the SVM.

Table 2. Procedure

If you want to modify the audit configuration for...	Enter...
Individual buckets	<code>vserver object-store-server audit event-selector modify -vserver <i>svm_name</i> [-bucket <i>bucket_name</i>] [<i>parameters to modify</i>]</code>
All buckets in the SVM	<code>vserver object-store-server audit modify -vserver <i>svm_name</i> [<i>parameters to modify</i>]</code>

Examples

The following example modifies an individual bucket auditing configuration to audit only write-only access

events:

```
cluster1::> vserver object-store-server audit event-selector modify  
-vserver vs1 -bucket test-bucket -access write-only
```

The following example modifies the auditing configuration of all buckets in the SVM to change the log size limit to 10MB and to retain 3 log files before rotating.

```
cluster1::> vserver object-store-server audit modify -vserver vs1  
-rotate-size 10MB -rotate-limit 3
```

= Show S3 auditing configurations

:icons: font

:relative_path: ./s3-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./smb-admin/..media/

After completing the auditing configuration, you can verify that auditing is configured properly and is enabled. You can also display information about all object store auditing configurations in the cluster.

About this task

You can display information about bucket and SVM auditing configurations.

- Buckets – use the `vserver object-store-server audit event-selector show` command

Without any parameters, the command displays the following information about buckets in all SVMs in the cluster with object store auditing configurations:

- SVM name
- Bucket name
- Access and permission values

- SVMs – use the `vserver object-store-server audit show` command

Without any parameters, the command displays the following information about all SVMs in the cluster with object store auditing configurations:

- SVM name
- Audit state
- Target directory

You can specify the `-fields` parameter to specify which audit configuration information to display.

Procedure

Show information about S3 auditing configurations:

If you want to modify the configuration for...	Enter...
Buckets	vserver object-store-server audit event-selector show [-vserver <i>svm_name</i>] [<i>parameters</i>]
SVMs	vserver object-store-server audit show [-vserver <i>svm_name</i>] [<i>parameters</i>]

Examples

The following example displays information for a single bucket:

```
cluster1::> vserver object-store-server audit event-selector show
-vserver vs1 -bucket test-bucket
      Vserver      Bucket      Access          Permission
----- -----
      vs1        bucket1    read-only      allow-only
```

The following example displays information for all buckets on an SVM:

```
cluster1::> vserver object-store-server audit event-selector show
-vserver vs1

      Vserver      :vs1
      Bucket       :test-bucket
      Access       :all
      Permission   :all
```

The following example displays the name, audit state, event types, log format, and target directory for all SVMs.

```
cluster1::> vserver object-store-server audit show

      Vserver      State  Event Types Log Format Target Directory
----- -----
      vs1        false   data      json      /audit_log
```

The following example displays the SVM names and details about the audit log for all SVMs.

```
cluster1::> vserver object-store-server audit show -log-save-details
```

Vserver	File Size	Rotation	Rotation Schedule	Limit
vs1	100MB	-	-	0

The following example displays in list form all audit configuration information about all SVMs.

```
cluster1::> vserver object-store-server audit show -instance
```

```
          Vserver: vs1
          Auditing state: true
          Log Destination Path: /audit_log
          Categories of Events to Audit: data
          Log Format: json
          Log File Size Limit: 100MB
          Log Rotation Schedule: Month: -
          Log Rotation Schedule: Day of Week: -
          Log Rotation Schedule: Day: -
          Log Rotation Schedule: Hour: -
          Log Rotation Schedule: Minute: -
          Rotation Schedules: -
          Log Files Rotation Limit: 0
          Log Retention Time: 0s
```

Beginning with ONTAP 9.7, you can manage cluster security with System Manager.

With System Manager, you use ONTAP standard methods to secure client and administrator access to storage and to protect against viruses. Advanced technologies are available for encryption of data at rest

and for WORM storage.

If you are using the classic System Manager (available only in ONTAP 9.7 and earlier), refer to [System Manager Classic \(ONTAP 9.0 to 9.7\)](#)

== Client authentication and authorization

ONTAP authenticates a client machine and user by verifying their identities with a trusted source. ONTAP authorizes a user to access a file or directory by comparing the user's credentials with the permissions configured on the file or directory.

== Administrator authentication and RBAC

Administrators use local or remote login accounts to authenticate themselves to the cluster and storage VM. Role-Based Access Control (RBAC) determines the commands to which an administrator has access.

== Virus scanning

You can use integrated antivirus functionality on the storage system to protect data from being compromised by viruses or other malicious code. ONTAP virus scanning, called *Vscan*, combines best-in-class third-party antivirus software with ONTAP features that give you the flexibility you need to control which files get scanned and when.

== Encryption

ONTAP offers both software- and hardware-based encryption technologies for ensuring that data at rest cannot be read if the storage medium is repurposed, returned, misplaced, or stolen.

== WORM storage

SnapLock is a high-performance compliance solution for organizations that use *write once, read many* (WORM) storage to retain critical files in unmodified form for regulatory and governance purposes.

= Set up multifactor authentication

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

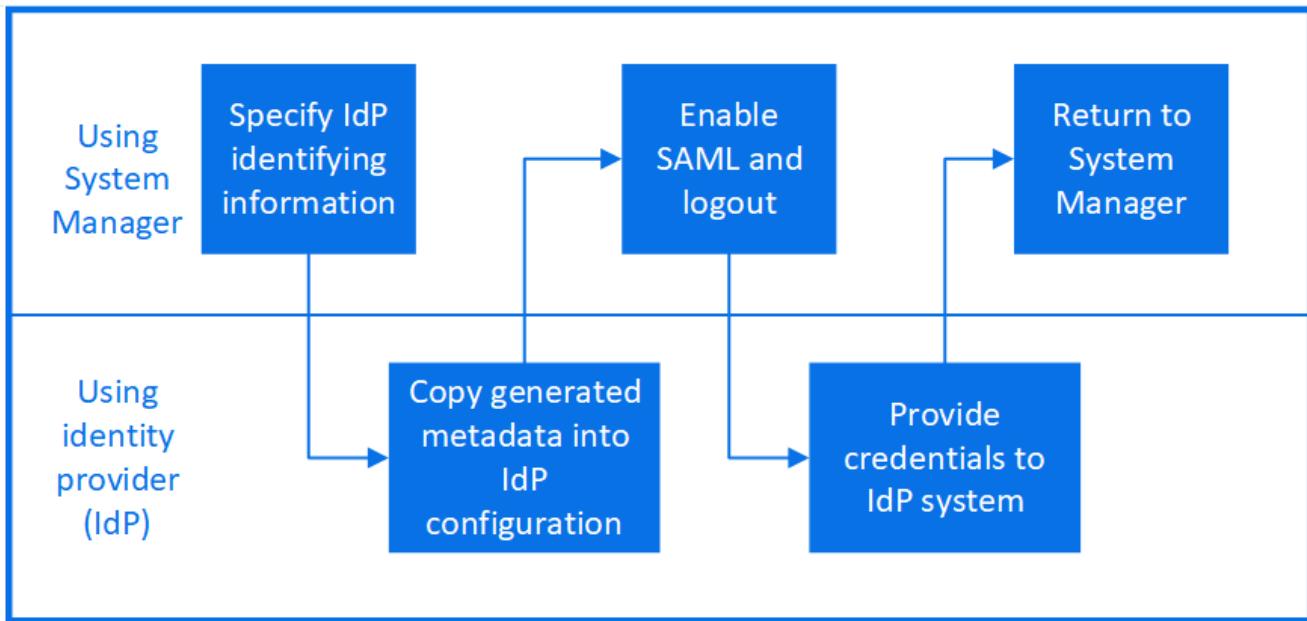

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/

Security Assertion Markup Language (SAML) authentication allows users to log in to an application by using a secure identity provider (IdP).

In System Manager, in addition to standard ONTAP authentication, SAML-based authentication is provided as an option for multifactor authentication.

Security Assertion Markup Language (SAML) is an XML-based framework for authentication and authorization between two entities: a service provider and an identity provider.

== Enable SAML authentication

To enable SAML authentication, perform the following steps:

Steps

1. Click **Cluster > Settings**.
2. Next to **SAML Authentication**, click .
3. Ensure there is a check in the **Enable SAML Authentication** checkbox.
4. Enter the URL of the IdP URI (including "https://").
5. Modify the host system address, if needed.
6. Ensure the correct certificate is being used:
 - If your system was mapped with only one certificate with type "server", then that certificate is considered the default and it isn't displayed.
 - If your system was mapped with multiple certificates as type "server", then one of the certificates is displayed. To select a different certificate, click **Change**.
7. Click **Save**. A confirmation window displays the metadata information, which has been automatically copied to your clipboard.
8. Go to the IdP system you specified and copy the metadata from your clipboard to update the system metadata.
9. Return to the confirmation window (in System Manager) and check the checkbox **I have configured the IdP with the host URI or metadata**.
10. Click **Logout** to enable SAML-based authentication. The IdP system will display an authentication screen.
11. In the IdP system, enter your SAML-based credentials. After your credentials are verified, you will be directed to the System Manager home page.

== Disable SAML authentication

To disable SAML authentication, perform the following steps:

Steps

1. Click **Cluster > Settings**.
2. Under **SAML Authentication**, click the **Enabled** toggle button.
3. *Optional:* You can also click  next to **SAML Authentication**, and then uncheck the **Enable SAML Authentication** checkbox.

= Control administrator access

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/

The role assigned to an administrator determines which functions the administrator can perform with System Manager. Predefined roles for cluster administrators and storage VM administrators are provided by System Manager. You assign the role when you create the administrator's account, or you can assign a different role later.

Depending on how you have enabled account access, you might need to perform any of the following:

- Associate a public key with a local account.
- Install a CA-signed server digital certificate.
- Configure AD, LDAP, or NIS access.

You can perform these tasks before or after enabling account access.

== Assigning a role to an administrator

Assign a role to an administrator, as follows:

Steps

1. Click **Cluster > Settings**.
2. Click  next to **Users and Roles**.
3. Click  **Add** under **Users**.
4. Specify a user name, and select a role in the drop-down menu for **Role**.
5. Specify a login method and password for the user.

== Changing an administrator's role

Change the role for an administrator, as follows:

Steps

1. Click **Cluster > Settings**.
2. Select the name of user whose role you want to change, then click the  that appears next to the user name.
3. Click **Edit**.
4. Select a role in the drop-down menu for **Role**.

= Diagnose and correct file access issues
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrs:
:relative_path: ./
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.smb-admin./media/

Steps

1. In System Manager, select **Storage > Storage VMs**.
2. Select the storage VM on which you want to perform a trace.
3. Click  **More**.
4. Click **Trace File Access**.
5. Provide the user name and client IP address, then click **Start Tracing**.

The trace results are displayed in a table. The **Reasons** column provides the reason why a file could not be accessed.

6. Click  in the left column of the results table to view the file access permissions.

= Manage certificates with System Manager

Beginning with ONTAP 9.10.1, you can use System Manager to manage trusted certificate authorities, client/server certificates, and local (onboard) certificate authorities.

With System Manager, you can manage the certificates received from other applications so you can authenticate communications from those applications. You can also manage your own certificates that identify your system to other applications.

== View certificate information

With System Manager, you can view trusted certificate authorities, client/server certificates, and local certificate authorities that are stored on the cluster.

Steps

1. In System Manager, click **Cluster > Settings**.
2. Scroll to the **Security** area.

In the **Certificates** section, the following details are displayed:

- The number of stored trusted certificate authorities.
 - The number of stored client/server certificates.
 - The number of stored local certificate authorities.
3. Click any number to view details about a category of certificates, or click  to view the **Certificates** page, which contains information about all categories.

The list displays the information for the entire cluster. If you want to display information for only a specific storage VM, perform the following steps:

- a. Click **Storage > Storage VMs**.
- b. Select the storage VM.
- c. View the **Settings** tab.
- d. Click a number shown in the **Certificate** section.

What to do next

- From the **Certificates** page, you can [\[Generate a certificate signing request\]](#).
- The certificate information is separated into three tabs, one for each category. You can perform the following tasks from each tab:

On this tab...	You can perform these procedures...
Trusted certificate authorities	<ul style="list-style-type: none"> • [install-trusted-cert] • [Delete a trusted certificate authority] • [Renew a trusted certificate authority]
Client/server certificates	<ul style="list-style-type: none"> • [install-cs-cert] • [gen-cs-cert] • [delete-cs-cert] • [renew-cs-cert]
Local certificate authorities	<ul style="list-style-type: none"> • [Create a new local certificate authority] • [Sign a certificate using a local certificate authority] • [Delete a local certificate authority] • [Renew a local certificate authority]

== Generate a certificate signing request

You can generate a certificate signing request (CSR) with System Manager from any tab of the **Certificates** page. A private key and a corresponding CSR are generated, which can be signed using a certificate authority to generate a public certificate.

Steps

1. View the **Certificates** page. See [\[View certificate information\]](#).
2. Click **+Generate CSR**.
3. Complete the information for the subject name:
 - a. Enter a **common name**.
 - b. Select a **country**.
 - c. Enter an **organization**.
 - d. Enter an **organization unit**.
4. If you want to override defaults, select **More Options** and provide additional information.

== Install (add) a trusted certificate authority

You can install additional trusted certificate authorities in System Manager.

Steps

1. View the **Trusted Certificate Authorities** tab. See [\[View certificate information\]](#).
2. Click  .
3. On the **Add Trusted Certificate Authority** panel, perform the following:
 - Enter a **name**.
 - For the **scope**, select a storage VM.
 - Enter a **common name**.
 - Select a **type**.
 - Enter or import **certificate details**.

== Delete a trusted certificate authority

With System Manager, you can delete a trusted certificate authority.

You cannot delete trusted certificate authorities that were preinstalled with ONTAP.

Steps

1. View the **Trusted Certificate Authorities** tab. See [\[View certificate information\]](#).
2. Click the name of the trusted certificate authority.
3. Click  next to the name, then click **Delete**.

== Renew a trusted certificate authority

With System Manager, you can renew a trusted certificate authority that has expired or is about to expire.

Steps

1. View the **Trusted Certificate Authorities** tab. See [\[View certificate information\]](#).
2. Click the name of the trusted certificate authority.
3. Click  next to the name, then click **Renew**.

== Install (add) a client/server certificate

With System Manager, you can install additional client/server certificates.

Steps

1. View the **Client/Server Certificates** tab. See [\[View certificate information\]](#).
2. Click  .
3. On the **Add Client/Server Certificate** panel, perform the following:
 - Enter a **certificate name**.
 - For the **scope**, select a storage VM.
 - Enter a **common name**.
 - Select a **type**.

- Enter or import **certificate details**.

You can either write in or copy and paste in the certificate details from a text file or you can import the text from a certificate file by clicking **Import**.

- Enter a the **private key**.

You can either write in or copy and paste in the private key from a text file or you can import the text from a private key file by clicking **Import**.

= Generate (add) a self-signed client/server certificate

With System Manager, you can generate additional self-signed client/server certificates.

Steps

1. View the **Client/Server Certificates** tab. See [\[View certificate information\]](#).
2. Click **+Generate Self-signed Certificate**.
3. On the **Generate Self-Signed Certificate** panel, perform the following:
 - Enter a **certificate name**.
 - For the **scope**, select a storage VM.
 - Enter a **common name**.
 - Select a **type**.
 - Select a **hash function**.
 - Select a **key size**.
 - Select a **storage VM**.

== Delete a client/server certificate

With System Manager, you can delete client/server certificates.

Steps

1. View the **Client/Server Certificates** tab. See [\[View certificate information\]](#).
2. Click the name of the client/server certificate.
3. Click  next to the name, then click **Delete**.

== Renew a client/server certificate

With System Manager, you can renew a client/server certificate that has expired or is about to expire.

Steps

1. View the **Client/Server Certificates** tab. See [\[View certificate information\]](#).
2. Click the name of the client/server certificate.
3. Click  next to the name, then click **Renew**.

== Create a new local certificate authority

With System Manager, you can create a new local certificate authority.

Steps

1. View the **Local Certificate Authorities** tab. See [\[View certificate information\]](#).
2. Click  .
3. On the **Add Local Certificate Authority** panel, perform the following:
 - Enter a **name**.
 - For the **scope**, select a storage VM.
 - Enter a **common name**.
4. If you want to override defaults, select **More Options** and provide additional information.

== Sign a certificate using a local certificate authority

In System Manager, you can use a local certificate authority to sign a certificate.

Steps

1. View the **Local Certificate Authorities** tab. See [\[View certificate information\]](#).
2. Click the name of the local certificate authority.
3. Click  next to the name, then click **Sign a certificate**.
4. Complete the **Sign a Certificate Signing Request** form.
 - You can either paste in the certificate signing content or import a certificate signing request file by clicking **Import**.
 - Specify the number of days for which the certificate will be valid.

== Delete a local certificate authority

With System Manager, you can delete a local certificate authority.

Steps

1. View the **Local Certificate Authority** tab. See [\[View certificate information\]](#).
2. Click the name of the local certificate authority.
3. Click  next to the name, then click **Delete**.

== Renew a local certificate authority

With System Manager, you can renew a local certificate authority that has expired or is about to expire.

Steps

1. View the **Local Certificate Authority** tab. See [\[View certificate information\]](#).
2. Click the name of the local certificate authority.
3. Click  next to the name, then click **Renew**.

= Manage administrator authentication and RBAC with the CLI

= Administrator authentication and RBAC overview with the CLI

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can enable login accounts for ONTAP cluster administrators and storage virtual machine (SVM) administrators. You can also use role-based access control (RBAC) to define the capabilities of administrators.

You enable login accounts and RBAC in the following ways:

- You want to use the ONTAP command-line interface (CLI), not System Manager or an automated scripting tool.
- You want to use best practices, not explore every available option.
- You are not using SNMP to collect information about the cluster.

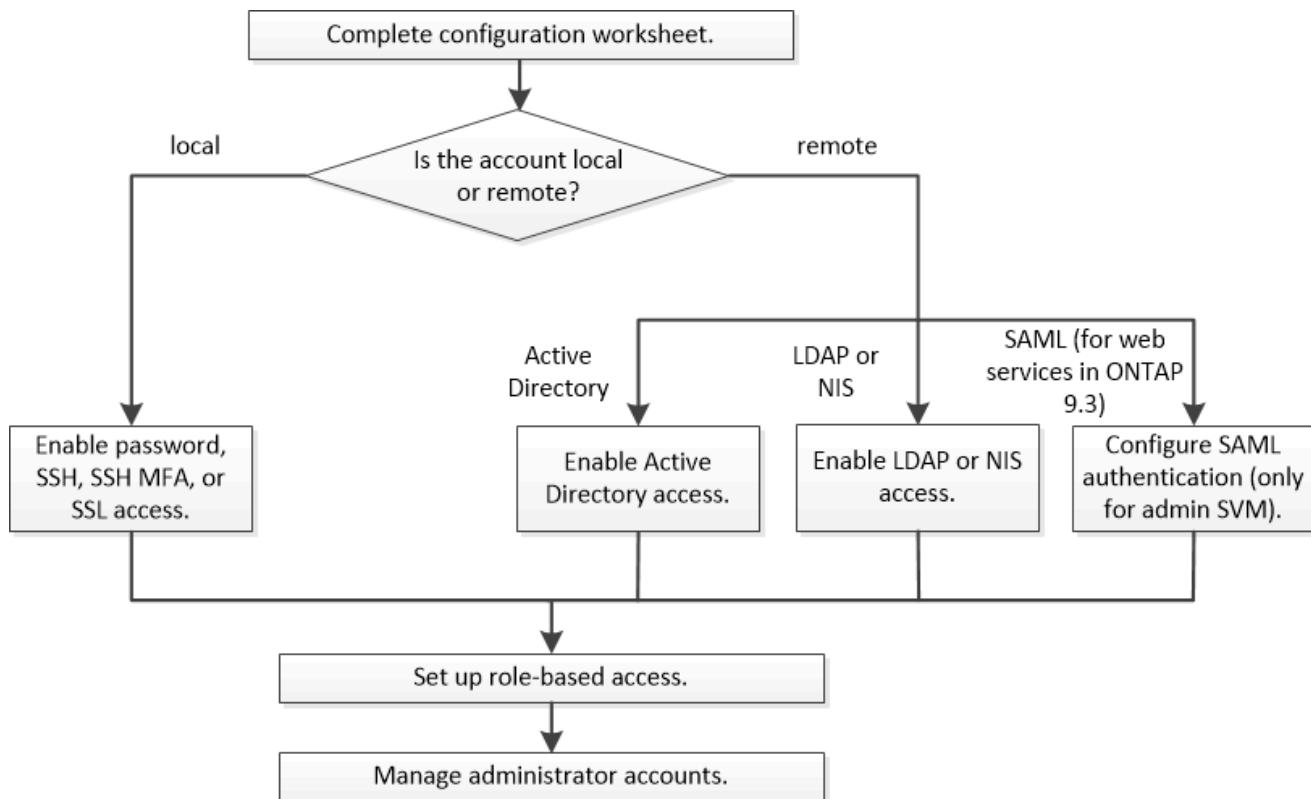

= Administrator authentication and RBAC workflow

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can enable authentication for local administrator accounts or remote administrator accounts. The account information for a local account resides on the storage system and the account information for a remote account resides elsewhere. Each account can have a predefined role or a custom role.

You can enable local administrator accounts to access an admin storage virtual machine (SVM) or a data SVM with the following types of authentication:

- Password
- SSH public key
- SSL certificate

- SSH multifactor authentication (MFA)

Beginning with ONTAP 9.3, authentication with password and public key is supported.

You can enable remote administrator accounts to access an admin SVM or a data SVM with the following types of authentication:

- Active Directory
- SAML authentication (only for admin SVM)

Beginning with ONTAP 9.3, Security Assertion Markup Language (SAML) authentication can be used for accessing the admin SVM by using any of the following web services: Service Processor Infrastructure, ONTAP APIs, or System Manager.

- Beginning with ONTAP 9.4, SSH MFA can be used for remote users on LDAP or NIS servers. Authentication with nsswitch and public key is supported.

= Worksheets for administrator authentication and RBAC configuration

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Before creating login accounts and setting up role-based access control (RBAC), you should gather information for each item in the configuration worksheets.

== Create or modify login accounts

You provide these values with the `security login create` command when you enable login accounts to access a storage virtual machine (SVM). You provide the same values with the `security login modify` command when you modify how an account accesses an SVM.

Field	Description	Your value
<code>-vserver</code>	The name of the SVM that the account accesses. The default value is the name of the admin SVM for the cluster.	
<code>-user-or-group-name</code>	The user name or group name of the account. Specifying a group name enables access to each user in the group. You can associate a user name or group name with multiple applications.	

-application	The application that is used to access the SVM: <ul style="list-style-type: none">• http• ontapi• snmp• ssh	
-authmethod	The method that is used to authenticate the account: <ul style="list-style-type: none">• cert for SSL certificate authentication• domain for Active Directory authentication• nsswitch for LDAP or NIS authentication• password for user password authentication• publickey for public key authentication• community for SNMP community strings• usm for SNMP user security model• saml for Security Assertion Markup Language (SAML) authentication	
-remote-switch-ipaddress	The IP address of the remote switch. The remote switch can be a cluster switch monitored by the cluster switch health monitor (CSHM) or a Fibre Channel (FC) switch monitored by the MetroCluster health monitor (MCC-HM). This option is applicable only when the application is <code>snmp</code> and the authentication method is <code>usm</code> .	

-role	<p>The access control role that is assigned to the account:</p> <ul style="list-style-type: none"> • For the cluster (the admin SVM), the default value is <code>admin</code>. • For a data SVM, the default value is <code>vsadmin</code>. 	
-comment	(Optional) Descriptive text for the account. You should enclose the text in double quotation marks (").	
-is-ns-switch-group	Whether the account is an LDAP group account or NIS group account (<code>yes</code> or <code>no</code>).	
-second-authentication -method	<p>Second authentication method in case of multifactor authentication in ONTAP 9.3:</p> <ul style="list-style-type: none"> • <code>none</code> if not using multifactor authentication, default value • <code>publickey</code> for public key authentication when the <code>authmethod</code> is <code>password</code> or <code>nsswitch</code> • <code>password</code> for user password authentication when the <code>authmethod</code> is <code>publickey</code> • <code>nsswitch</code> for user password authentication when the <code>authmethod</code> is <code>publickey</code> <p> Support for <code>nsswitch</code> is available from ONTAP 9.4</p> <p>The order of authentication is always the public key followed by the password.</p>	

== Define custom roles

You provide these values with the `security login role create` command when you define a custom role.

Field	Description	Your value
-vserver	(Optional) The name of the SVM that is associated with the role.	
-role	The name of the role.	
-cmddirname	The command or command directory to which the role gives access. You should enclose command subdirectory names in double quotation marks ("). For example, "volume snapshot". You must enter DEFAULT to specify all command directories.	
-access	<p>(Optional) The access level for the role. For command directories:</p> <ul style="list-style-type: none"> • none (the default value for custom roles) denies access to commands in the command directory • readonly grants access to the show commands in the command directory and its subdirectories • all grants access to all of the commands in the command directory and its subdirectories <p>For <i>nonintrinsic commands</i> (commands that do not end in create, modify, delete, or show):</p> <ul style="list-style-type: none"> • none (the default value for custom roles) denies access to the command • readonly is not applicable • all grants access to the command <p>To grant or deny access to intrinsic commands, you must specify the command directory.</p>	

-query	(Optional) The query object that is used to filter the access level, which is specified in the form of a valid option for the command or for a command in the command directory. You should enclose the query object in double quotation marks ("). For example, if the command directory is volume, the query object "-aggr aggr0" would enable access for the aggr0 aggregate only.
--------	---

== Associate a public key with a user account

You provide these values with the `security login publickey create` command when you associate an SSH public key with a user account.

Field	Description	Your value
-vserver	(Optional) The name of the SVM that the account accesses.	
-username	The user name of the account. The default value, admin, which is the default name of the cluster administrator.	
-index	The index number of the public key. The default value is 0 if the key is the first key that is created for the account; otherwise, the default value is one more than the highest existing index number for the account.	
-publickey	The OpenSSH public key. You should enclose the key in double quotation marks (").	
-role	The access control role that is assigned to the account.	
-comment	(Optional) Descriptive text for the public key. You should enclose the text in double quotation marks (").	

== Install a CA-signed server digital certificate

You provide these values with the `security certificate generate-csr` command when you generate a digital certificate signing request (CSR) for use in authenticating an SVM as an SSL server.

Field	Description	Your value
<code>-common-name</code>	The name of the certificate, which is either a fully qualified domain name (FQDN) or a custom common name.	
<code>-size</code>	The number of bits in the private key. The higher the value, the more secure the key. The default value is 2048. Possible values are 512, 1024, 1536, and 2048.	
<code>-country</code>	The country of the SVM, in a two-letter code. The default value is US. See the man pages for a list of codes.	
<code>-state</code>	The state or province of the SVM.	
<code>-locality</code>	The locality of the SVM.	
<code>-organization</code>	The organization of the SVM.	
<code>-unit</code>	The unit in the organization of the SVM.	
<code>-email-addr</code>	The email address of the contact administrator for the SVM.	
<code>-hash-function</code>	The cryptographic hashing function for signing the certificate. The default value is SHA256. Possible values are SHA1, SHA256, and MD5.	

You provide these values with the `security certificate install` command when you install a CA-signed digital certificate for use in authenticating the cluster or SVM as an SSL server. Only the options that are relevant to this guide are shown in the following table.

Field	Description	Your value
<code>-vserver</code>	The name of the SVM on which the certificate is to be installed.	

-type	<p>The certificate type:</p> <ul style="list-style-type: none"> • <code>server</code> for server certificates and intermediate certificates • <code>client-ca</code> for the public key certificate of the root CA of the SSL client • <code>server-ca</code> for the public key certificate of the root CA of the SSL server of which ONTAP is a client • <code>client</code> for a self-signed or CA-signed digital certificate and private key for ONTAP as an SSL client 	
-------	--	--

== Configure Active Directory domain controller access

You provide these values with the `security login domain-tunnel create` command when you have already configured a SMB server for a data SVM and you want to configure the SVM as a gateway or *tunnel* for Active Directory domain controller access to the cluster.

Field	Description	Your value
<code>-vserver</code>	The name of the SVM for which the SMB server has been configured.	

You provide these values with the `vserver active-directory create` command when you have not configured a SMB server and you want to create an SVM computer account on the Active Directory domain.

Field	Description	Your value
<code>-vserver</code>	The name of the SVM for which you want to create an Active Directory computer account.	
<code>-account-name</code>	The NetBIOS name of the computer account.	
<code>-domain</code>	The fully qualified domain name (FQDN).	

-ou	The organizational unit in the domain. The default value is CN=Computers. ONTAP appends this value to the domain name to produce the Active Directory distinguished name.
-----	---

== Configure LDAP or NIS server access

You provide these values with the `vserver services name-service ldap client create` command when you create an LDAP client configuration for the SVM.

Beginning with ONTAP 9.2, the `-ldap-servers` field replaces the `-servers` field. This new field can take either a host name or an IP address as the value for the LDAP server.

Only the options that are relevant to this guide are shown in the following table:

Field	Description	Your value
<code>-vserver</code>	The name of the SVM for the client configuration.	
<code>-client-config</code>	The name of the client configuration.	
<code>-servers</code>	ONTAP 9.0, 9.1: A comma-separated list of IP addresses for the LDAP servers to which the client connects.	
<code>-ldap-servers</code>	ONTAP 9.2: A comma-separated list of IP addresses and host names for the LDAP servers to which the client connects.	
<code>-schema</code>	The schema that the client uses to make LDAP queries.	

-use-start-tls	<p>Whether the client uses Start TLS to encrypt communication with the LDAP server (true or false).</p> <p> Start TLS is supported for access to data SVMs only. It is not supported for access to admin SVMs.</p>	
----------------	---	--

You provide these values with the `vserver services name-service ldap create` command when you associate an LDAP client configuration with the SVM.

Field	Description	Your value
-vserver	The name of the SVM with which the client configuration is to be associated.	
-client-config	The name of the client configuration.	
-client-enabled	Whether the SVM can use the LDAP client configuration (true or false).	

You provide these values with the `vserver services name-service nis-domain create` command when you create an NIS domain configuration on an SVM.

Beginning with ONTAP 9.2, the `-nis-servers` field replaces the `-servers` field. This new field can take either a host name or an IP address as the value for the NIS server.

Field	Description	Your value
-vserver	The name of the SVM on which the domain configuration is to be created.	
-domain	The name of the domain.	
-active	Whether the domain is active (true or false).	

-servers	ONTAP 9.0, 9.1: A comma-separated list of IP addresses for the NIS servers that are used by the domain configuration.	
-nis-servers	ONTAP 9.2: A comma-separated list of IP addresses and host names for the NIS servers that are used by the domain configuration.	

You provide these values with the `vserver services name-service ns-switch create` command when you specify the look-up order for name service sources.

Field	Description	Your value
-vserver	The name of the SVM on which the name service look-up order is to be configured.	
-database	The name service database: <ul style="list-style-type: none"> • hosts for files and DNS name services • group for files, LDAP, and NIS name services • passwd for files, LDAP, and NIS name services • netgroup for files, LDAP, and NIS name services • namemap for files and LDAP name services 	
-sources	The order in which to look up name service sources (in a comma-separated list): <ul style="list-style-type: none"> • files • dns • ldap • nis 	

== Configure SAML access

Beginning with ONTAP 9.3, you provide these values with the `security saml-sp create` command to configure SAML authentication.

Field	Description	Your value
-idp-uri	The FTP address or HTTP address of the Identity Provider (IdP) host from where the IdP metadata can be downloaded.	
-sp-host	The host name or IP address of the SAML service provider host (ONTAP system). By default, the IP address of the cluster-management LIF is used.	
{[-cert-ca] and -cert-serial} or [-cert-common-name]	The server certificate details of the service provider host (ONTAP system).	
-verify-metadata-server	Whether the identity of the IdP metadata server must be validated (true or false). The best practice is to always set this value to true.	

= Create login accounts

= Create login accounts overview

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can enable local or remote cluster and SVM administrator accounts. A local account is one in which the account information, public key, or security certificate resides on the storage system. AD account information is stored on a domain controller. LDAP and NIS accounts reside on LDAP and NIS servers.

-- Cluster and SVM administrators

A *cluster administrator* accesses the admin SVM for the cluster. The admin SVM and a cluster administrator with the reserved name `admin` are automatically created when the cluster is set up.

A cluster administrator with the default `admin` role can administer the entire cluster and its resources. The cluster administrator can create additional cluster administrators with different roles as needed.

An *SVM administrator* accesses a data SVM. The cluster administrator creates data SVMs and SVM administrators as needed.

SVM administrators are assigned the `vsadmin` role by default. The cluster administrator can assign different roles to SVM administrators as needed.

 The following generic names cannot be used for remote cluster and SVM administrator accounts: "adm", "bin", "cli", "daemon", "ftp", "games", "halt", "lp", "mail", "man", "nroot", "netapp", "news", "nobody", "operator", "root", "shutdown", "sshd", "sync", "sys", "uucp", and "www".

== Merged roles

If you enable multiple remote accounts for the same user, the user is assigned the union of all roles specified for the accounts. That is, if an LDAP or NIS account is assigned the `vsadmin` role, and the AD group account for the same user is assigned the `vsadmin-volume` role, the AD user logs in with the more inclusive `vsadmin` capabilities. The roles are said to be *merged*.

= Enable local account access

= Enable local account access overview

:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

A local account is one in which the account information, public key, or security certificate resides on the storage system. You can use the `security login create` command to enable local accounts to access an admin or data SVM.

= Enable password account access

:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use the `security login create` command to enable administrator accounts to access an admin or data SVM with a password. You are prompted for the password after you enter the command.

What you'll need

You must be a cluster administrator to perform this task.

About this task

If you are unsure of the access control role that you want to assign to the login account, you can use the `security login modify` command to add the role later.

Step

1. Enable local administrator accounts to access an SVM using a password:

```
security login create -vserver SVM_name -user-or-group-name
user_or_group_name -application application -authmethod
authentication_method -role role -comment comment
```

For complete command syntax, see the [worksheet](#).

The following command enables the cluster administrator account `admin1` with the predefined `backup` role to access the `admin` SVM `engCluster` using a password. You are prompted for the password after you enter the command.

```
cluster1::>security login create -vserver engCluster -user-or-group-name admin1 -application ssh -authmethod password -role backup
```

= Enable SSH public key accounts
:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use the `security login create` command to enable administrator accounts to access an admin or data SVM with an SSH public key.

What you'll need

You must be a cluster administrator to perform this task.

About this task

- You must associate the public key with the account before the account can access the SVM.

[Associating a public key with a user account](#)

You can perform this task before or after you enable account access.

- If you are unsure of the access control role that you want to assign to the login account, you can use the `security login modify` command to add the role later.

If you want to enable SSL FIPS mode on a cluster where administrator accounts authenticate with an SSH public key before accessing SVMs, you must ensure that the host key algorithm is supported before enabling FIPS.

- Supported key types: ecdsa-sha2-nistp256, ssh-ed25519
- Unsupported key types: ssh-rsa, ssh-dss

Existing SSH public key accounts without the supported key algorithms must be reconfigured with a supported key type before enabling FIPS, or the administrator authentication will fail.

For more information, see [Configure network security using FIPS](#).

Step

1. Enable local administrator accounts to access an SVM using an SSH public key:

```
security login create -vserver SVM_name -user-or-group-name  
user_or_group_name -application application -authmethod  
authentication_method -role role -comment comment
```

For complete command syntax, see the [worksheet](#).

The following command enables the SVM administrator account `svmadmin1` with the predefined `vsadmin-volume` role to access the `SVMengData1` using an SSH public key:

```
cluster1::>security login create -vserver engData1 -user-or-group  
-name svadmin1 -application ssh -authmethod publickey -role  
vsadmin-volume
```

After you finish

If you have not associated a public key with the administrator account, you must do so before the account can access the SVM.

[Associating a public key with a user account](#)

= Enable SSH multifactor authentication (MFA)

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Beginning with ONTAP 9.3, you can use the `security login create` command to enhance security by requiring that administrators log in to an admin or data SVM with both an SSH public key and a user password.

What you'll need

You must be a cluster administrator to perform this task.

About this task

- You must associate the public key with the account before the account can access the SVM.

[Associating a public key with a user account](#)

You can perform this task before or after you enable account access.

- If you are unsure of the access control role that you want to assign to the login account, you can use the `security login modify` command to add the role later.

[Modifying the role assigned to an administrator](#)

- The user is always authenticated with public key authentication followed by password authentication.

Step

1. Require local administrator accounts to access an SVM using SSH MFA:

```
security login create -vserver SVM -user-or-group-name user_name  
-application ssh -authentication-method password|publickey -role admin  
-second-authentication-method password|publickey
```

The following command requires the SVM administrator account `admin2` with the predefined `admin` role to log in to the SVM `engData1` with both an SSH public key and a user password:

```
cluster-1::> security login create -vserver engData1 -user-or-group-name admin2 -application ssh -authentication-method publickey -role admin -second-authentication-method password

Please enter a password for user 'admin2':
Please enter it again:
Warning: To use public-key authentication, you must create a public key for user "admin2".
```

After you finish

If you have not associated a public key with the administrator account, you must do so before the account can access the SVM.

Associating a public key with a user account

= Enable SSL certificate accounts
:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use the `security login create` command to enable administrator accounts to access an admin or data SVM with an SSL certificate.

What you'll need

You must be a cluster administrator to perform this task.

About this task

- You must install a CA-signed server digital certificate before the account can access the SVM.

Generating and installing a CA-signed server certificate

You can perform this task before or after you enable account access.

- If you are unsure of the access control role you want to assign to the login account, you can add the role later with the `security login modify` command.

Modifying the role assigned to an administrator

For cluster administrator accounts, certificate authentication is supported only with the `http` and `ontapi` applications. For SVM administrator accounts, certificate authentication is supported only with the `ontapi` application.

Step

1. Enable local administrator accounts to access an SVM using an SSL certificate:

```
security login create -vserver SVM_name -user-or-group-name user_or_group_name -application application -authmethod authentication_method -role role -comment comment
```

For complete command syntax, see the [ONTAP man pages by release](#).

The following command enables the SVM administrator account `svmadmin2` with the default `vsadmin` role to access the SVM `engData2` using an SSL digital certificate.

```
cluster1::>security login create -vserver engData2 -user-or-group-name svmadmin2 -application ontapi -authmethod cert
```

After you finish

If you have not installed a CA-signed server digital certificate, you must do so before the account can access the SVM.

[Generating and installing a CA-signed server certificate](#)

= Enable Active Directory account access

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use the `security login create` command to enable Active Directory (AD) user or group accounts to access an admin or data SVM. Any user in the AD group can access the SVM with the role that is assigned to the group.

What you'll need

- The cluster time must be synchronized to within five minutes of the time on the AD domain controller.
- You must be a cluster administrator to perform this task.

About this task

- You must configure AD domain controller access to the cluster or SVM before the account can access the SVM.

[Configuring Active Directory domain controller access](#)

You can perform this task before or after you enable account access.

- If you are unsure of the access control role that you want to assign to the login account, you can use the `security login modify` command to add the role later.

[Modifying the role assigned to an administrator](#)

AD group account access is supported only with the `SSH` and `ontapi` applications.

Step

1. Enable AD user or group administrator accounts to access an SVM:

```
security login create -vserver SVM_name -user-or-group-name user_or_group_name -application application -authmethod domain -role role -comment comment
```

For complete command syntax, see the [worksheet](#).

Creating or modifying login accounts

The following command enables the AD cluster administrator account DOMAIN1\guest1 with the predefined backup role to access the admin SVMengCluster.

```
cluster1::>security login create -vserver engCluster -user-or-group  
-name DOMAIN1\guest1 -application ssh -authmethod domain -role  
backup
```

The following command enables the SVM administrator accounts in the AD group account DOMAIN1\adgroup with the predefined vsadmin-volume role to access the SVMengData.

```
cluster1::>security login create -vserver engData -user-or-group  
-name DOMAIN1\adgroup -application ssh -authmethod domain -role  
vsadmin-volume
```

After you finish

If you have not configured AD domain controller access to the cluster or SVM, you must do so before the account can access the SVM.

Configuring Active Directory domain controller access

= Enable LDAP or NIS account access
:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use the security login create command to enable LDAP or NIS user accounts to access an admin or data SVM. If you have not configured LDAP or NIS server access to the SVM, you must do so before the account can access the SVM.

What you'll need

You must be a cluster administrator to perform this task.

About this task

- Group accounts are not supported.
- You must configure LDAP or NIS server access to the SVM before the account can access the SVM.

Configuring LDAP or NIS server access

You can perform this task before or after you enable account access.

- If you are unsure of the access control role that you want to assign to the login account, you can use the security login modify command to add the role later.

Modifying the role assigned to an administrator

- Beginning with ONTAP 9.4, multifactor authentication (MFA) is supported for remote users over LDAP or NIS servers.
- Because of a known LDAP issue, you should not use the ' : ' (colon) character in any field of LDAP user account information (for example, gecos, userPassword, and so on). Otherwise, the lookup operation will fail for that user.

Steps

1. Enable LDAP or NIS user or group accounts to access an SVM:

```
security login create -vserver SVM_name -user-or-group-name user_name
-application application -authmethod nsswitch -role role -comment comment
-is-ns-switch-group yes|no
```

For complete command syntax, see the [worksheet](#).

[Creating or modifying login accounts](#)

The following command enables the LDAP or NIS cluster administrator account guest2 with the predefined backup role to access the admin SVMengCluster.

```
cluster1::>security login create -vserver engCluster -user-or-group
-name guest2 -application ssh -authmethod nsswitch -role backup
```

2. Enable MFA login for LDAP or NIS users:

```
security login modify -user-or-group-name rem_usr1 -application ssh
-authentication-method nsswitch -role admin -is-ns-switch-group no -second
-authentication-method publickey
```

The authentication method can be specified as publickey and second authentication method as nsswitch.

The following example shows the MFA authentication being enabled:

```
cluster-1::*> security login modify -user-or-group-name rem_usr2
-application ssh -authentication-method nsswitch -vserver
cluster-1 -second-authentication-method publickey"
```

After you finish

If you have not configured LDAP or NIS server access to the SVM, you must do so before the account can access the SVM.

[Configuring LDAP or NIS server access](#)

= Configure SAML authentication
:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Beginning with ONTAP 9.3, you can configure Security Assertion Markup Language (SAML) authentication for web services. When SAML authentication is configured and enabled, users are authenticated by an external Identity Provider (IdP) instead of the directory service providers such as Active Directory and LDAP.

What you'll need

- You must have configured the IdP for SAML authentication.
- You must have the IdP URI.

About this task

- SAML authentication applies only to the `http` and `ontapi` applications.

The `http` and `ontapi` applications are used by the following web services: Service Processor Infrastructure, ONTAP APIs, or System Manager.

- SAML authentication is applicable only for accessing the admin SVM.

Steps

1. Create a SAML configuration so that ONTAP can access the IdP metadata:

```
security saml-sp create -idp-uri idp_uri -sp-host ontap_host_name
```

`idp_uri` is the FTP or HTTP address of the IdP host from where the IdP metadata can be downloaded.

`ontap_host_name` is the host name or IP address of the SAML service provider host, which in this case is the ONTAP system. By default, the IP address of the cluster-management LIF is used.

You can optionally provide the ONTAP server certificate information. By default, the ONTAP web server certificate information is used.

```
cluster_12::> security saml-sp create -idp-uri  
https://scspr0235321001.gdl.englab.netapp.com/idp/shibboleth -verify  
-metadata-server false
```

Warning: This restarts the web server. Any HTTP/S connections that are active

will be disrupted.

Do you want to continue? {y|n}: y

[Job 179] Job succeeded: Access the SAML SP metadata using the URL:
`https://10.63.56.150/saml-sp/Metadata`

Configure the IdP and Data ONTAP users for the same directory server domain to ensure that users are the same for different authentication methods. See the "security login show" command for the Data ONTAP user configuration.

The URL to access the ONTAP host metadata is displayed.

- From the IdP host, configure the IdP with the ONTAP host metadata.

For more information about configuring the IdP, see the IdP documentation.

- Enable SAML configuration:

```
security saml-sp modify -is-enabled true
```

Any existing user that accesses the `http` or `ontapi` application is automatically configured for SAML authentication.

- If you want to create users for the `http` or `ontapi` application after SAML is configured, specify SAML as the authentication method for the new users.

- Create a login method for new users with SAML authentication: `security login create -user-or-group-name user_name -application [http | ontapi] -authentication-method saml -vserver svm_name`

```
cluster_12::> security login create -user-or-group-name admin1  
-application http -authentication-method saml -vserver  
cluster_12
```

- Verify that the user entry is created:

```
security login show
```

```

cluster_12::> security login show

Vserver: cluster_12

Second

```

Related information

[ONTAP 9 commands](#)

= Manage access-control roles

= Manage access-control roles overview

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

The role assigned to an administrator determines the commands to which the administrator has access. You assign the role when you create the account for the administrator. You can assign a different role or define custom roles as needed.

= Modify the role assigned to an administrator

```
:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

You can use the `security login modify` command to change the role of a cluster or SVM administrator account. You can assign a predefined or custom role.

What you'll need

You must be a cluster administrator to perform this task.

Step

1. Change the role of a cluster or SVM administrator:

```
security login modify -vserver SVM_name -user-or-group-name
user_or_group_name -application application -authmethod
authentication_method -role role -comment comment
```

For complete command syntax, see the [worksheet](#).

[Creating or modifying login accounts](#)

The following command changes the role of the AD cluster administrator account `DOMAIN1\guest1` to the predefined `readonly` role.

```
cluster1::>security login modify -vserver engCluster -user-or-group
-name DOMAIN1\guest1 -application ssh -authmethod domain -role
readonly
```

The following command changes the role of the SVM administrator accounts in the AD group account `DOMAIN1\adgroup` to the custom `vol_role` role.

```
cluster1::>security login modify -vserver engData -user-or-group
-name DOMAIN1\adgroup -application ssh -authmethod domain -role
vol_role
```

= Define custom roles

```
:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

You can use the `security login role create` command to define a custom role. You can execute the command as many times as necessary to achieve the exact combination of capabilities that you want to associate with the role.

What you'll need

You must be a cluster administrator to perform this task.

About this task

- A role, whether predefined or custom, grants or denies access to ONTAP commands or command directories.

A command directory (volume, for example) is a group of related commands and command subdirectories. Except as described in this procedure, granting or denying access to a command directory grants or denies access to each command in the directory and its subdirectories.

- Specific command access or subdirectory access overrides parent directory access.

If a role is defined with a command directory, and then is defined again with a different access level for a specific command or for a subdirectory of the parent directory, the access level that is specified for the command or subdirectory overrides that of the parent.

You cannot assign an SVM administrator a role that gives access to a command or command directory that is available only to the admin cluster administrator—for example, the security command directory.

Step

1. Define a custom role:

```
security login role create -vserver SVM_name -role role -cmddirname
command_or_directory_name -access access_level -query query
```

For complete command syntax, see the [worksheet](#).

The following commands grant the vol_role role full access to the commands in the volume command directory and read-only access to the commands in the volume snapshot subdirectory.

```
cluster1::>security login role create -role vol_role -cmddirname
"volume" -access all

cluster1::>security login role create -role vol_role -cmddirname
"volume snapshot" -access readonly
```

The following commands grant the SVM_storage role read-only access to the commands in the storage command directory, no access to the commands in the storage encryption subdirectory, and full access to the storage aggregate plex offline nonintrinsic command.

```
cluster1::>security login role create -role SVM_storage -cmddirname
"storage" -access readonly

cluster1::>security login role create -role SVM_storage -cmddirname
"storage encryption" -access none

cluster1::>security login role create -role SVM_storage -cmddirname
"storage aggregate plex offline" -access all
```

= Predefined roles for cluster administrators

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

The predefined roles for cluster administrators should meet most of your needs. You can create custom roles as necessary. By default, a cluster administrator is assigned the predefined `admin` role.

The following table lists the predefined roles for cluster administrators:

This role...	Has this level of access...	To the following commands or command directories
admin	all	All command directories (DEFAULT)
autosupport	all	<ul style="list-style-type: none">• set• system node autosupport
	none	All other command directories (DEFAULT)
backup	all	vserver services ndmp
	readonly	volume
	none	All other command directories (DEFAULT)
readonly	all	<ul style="list-style-type: none">• security login password• set
	none	security
	readonly	All other command directories (DEFAULT)
none	none	All command directories (DEFAULT)

The `autosupport` role is assigned to the predefined `autosupport` account, which is used by AutoSupport OnDemand. ONTAP prevents you from modifying or deleting the `autosupport` account. ONTAP also prevents you from assigning the `autosupport` role to other user accounts.

= Predefined roles for SVM administrators

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

The predefined roles for SVM administrators should meet most of your needs. You can create custom roles as necessary. By default, an SVM administrator is assigned the predefined `vsadmin` role.

The following table lists the predefined roles for SVM administrators:

Role name	Capabilities
vsadmin	<ul style="list-style-type: none">• Managing own user account local password and key information• Managing volumes, except volume moves• Managing quotas, qtrees, Snapshot copies, and files• Managing LUNs• Performing SnapLock operations, except privileged delete• Configuring protocols: NFS, SMB, iSCSI, and FC, including FCoE• Configuring services: DNS, LDAP, and NIS• Monitoring jobs• Monitoring network connections and network interface• Monitoring the health of the SVM

vsadmin-volume	<ul style="list-style-type: none"> • Managing own user account local password and key information • Managing volumes, including volume moves • Managing quotas, qtrees, Snapshot copies, and files • Managing LUNs • Configuring protocols: NFS, SMB, iSCSI, and FC, including FCoE • Configuring services: DNS, LDAP, and NIS • Monitoring network interface • Monitoring the health of the SVM
vsadmin-protocol	<ul style="list-style-type: none"> • Managing own user account local password and key information • Configuring protocols: NFS, SMB, iSCSI, and FC, including FCoE • Configuring services: DNS, LDAP, and NIS • Managing LUNs • Monitoring network interface • Monitoring the health of the SVM
vsadmin-backup	<ul style="list-style-type: none"> • Managing own user account local password and key information • Managing NDMP operations • Making a restored volume read/write • Managing SnapMirror relationships and Snapshot copies • Viewing volumes and network information
vsadmin-snaplock	<ul style="list-style-type: none"> • Managing own user account local password and key information • Managing volumes, except volume moves • Managing quotas, qtrees, Snapshot copies, and files • Performing SnapLock operations, including privileged delete • Configuring protocols: NFS and SMB • Configuring services: DNS, LDAP, and NIS • Monitoring jobs • Monitoring network connections and network interface

vsadmin_READONLY

- Managing own user account local password and key information
- Monitoring the health of the SVM
- Monitoring network interface
- Viewing volumes and LUNs
- Viewing services and protocols

= Manage administrator accounts

= Manage administrator accounts overview

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Depending on how you have enabled account access, you may need to associate a public key with a local account, install a CA-signed server digital certificate, or configure AD, LDAP, or NIS access. You can perform all of these tasks before or after enabling account access.

= Associate a public key with an administrator account

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

For SSH public key authentication, you must associate the public key with an administrator account before the account can access the SVM. You can use the security login publickey create command to associate a key with an administrator account.

What you'll need

- You must have generated the SSH key.
- You must be a cluster or SVM administrator to perform this task.

About this task

If you authenticate an account over SSH with both a password and an SSH public key, the account is authenticated first with the public key.

Step

1. Associate a public key with an administrator account:

```
security login publickey create -vserver SVM_name -username user_name  
-index index -publickey certificate -comment comment
```

For complete command syntax, see the [worksheet](#).

Associating a public key with a user account

The following command associates a public key with the SVM administrator account `svadmin1` for

the SVM engData1. The public key is assigned index number 5.

```
cluster1::>security login publickey create -vserver engData1  
-username svadmin1 -index 5 -publickey  
"ssh-rsa AAAAB3NzaC1yc2EAAAQABIAQH64CYbUsDQCdW22JnK6J  
/vU9upnKzd2zAk9C1f7YaWRUAFNs2Qe51UmQ3ldi8AD0Vfbr5T6HZPCixNAIza  
FcIDy7hgnmdj9eNGedGr/JNrftQbLD1hZybX+72DpQB0tYWBhe6eDJ1oPlob  
ZBGfM1PXh8VjeU44i7W4+s0hG0E=tsmith@publickey.example.com"
```

= Generate and install a CA-signed server certificate

= Generate and install a CA-signed server certificate overview

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

On production systems, it is a best practice to install a CA-signed digital certificate for use in authenticating the cluster or SVM as an SSL server. You can use the security certificate generate-csr command to generate a certificate signing request (CSR), and the security certificate install command to install the certificate you receive back from the certificate authority.

= Generate a certificate signing request

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

You can use the security certificate generate-csr command to generate a certificate signing request (CSR). After processing your request, the certificate authority (CA) sends you the signed digital certificate.

What you'll need

You must be a cluster or SVM administrator to perform this task.

Steps

1. Generate a CSR:

```
security certificate generate-csr -common-name FQDN_or_common_name -size  
512|1024|1536|2048 -country country -state state -locality locality  
-organization organization -unit unit -email-addr email_of_contact -hash  
-function SHA1|SHA256|MD5
```

The following command creates a CSR with a 2048-bit private key generated by the SHA256 hashing function for use by the Software group in the IT department of a company whose custom common name is server1.companyname.com, located in Sunnyvale, California, USA. The email address of the SVM contact administrator is web@example.com. The system displays the CSR and the private key in the output.

```
cluster1::>security certificate generate-csr -common-name  
server1.companyname.com -size 2048 -country US -state California  
-locality Sunnyvale -organization IT -unit Software -email-addr  
web@example.com -hash-function SHA256
```

Certificate Signing Request :

-----END RSA PRIVATE KEY-----
```

Note: Please keep a copy of your certificate request and private key for future reference.

2. Copy the certificate request from the CSR output, and send it in electronic form (such as email) to a trusted third-party CA for signing.

After processing your request, the CA sends you the signed digital certificate. You should keep a copy of the private key and the CA-signed digital certificate.

= Install a CA-signed server certificate

```
:icons: font  
:relative_path: ./authentication/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

You can use the security certificate install command to install a CA-signed server certificate on an SVM. ONTAP prompts you for the certificate authority (CA) root and intermediate certificates that form the certificate chain of the server certificate.

What you'll need

You must be a cluster or SVM administrator to perform this task.

Step

1. Install a CA-signed server certificate: `security certificate install -vserver SVM_name -type certificate_type`

For complete command syntax, see the [worksheet](#).

ONTAP prompts you for the CA root and intermediate certificates that form the certificate chain of the server certificate. The chain starts with the certificate of the CA that issued the server certificate, and can range up to the root certificate of the CA. Any missing intermediate certificates result in the failure of server certificate installation.

The following command installs the CA-signed server certificate and intermediate certificates on the SVMengData2.

```
cluster1::>security certificate install -vserver engData2 -type
server

= Configure Active Directory domain controller access

= Configure Active Directory domain controller access overview

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

You must configure AD domain controller access to the cluster or SVM before an AD account can access the SVM. If you have already configured a SMB server for a data SVM, you can configure the SVM as a gateway, or *tunnel*, for AD access to the cluster. If you have not configured a SMB server, you can create a computer account for the SVM on the AD domain.

ONTAP supports the following domain controller authentication services:

- Kerberos

- LDAP
- Netlogon
- Local Security Authority (LSA)

ONTAP supports the following session key algorithms for secure Netlogon connections:

Session key algorithm	Available in...
HMAC-SHA256, based on the Advanced Encryption Standard (AES)	ONTAP 9.10.1 and later
DES and HMAC-MD5 (when strong key is set)	All ONTAP 9 releases

If you want to use AES session keys during Netlogon secure channel establishment in ONTAP 9.10.1 and later, you must enable them using the following command:

```
cifs security modify -vserver vs1 -aes-enabled-for-netlogon-channel true
```

The default is false.

In ONTAP releases earlier than 9.10.1, if the domain controller enforces AES for secure Netlogon services, the connection fails. The domain controller must be configured to accept strong key connections with ONTAP in these releases.

= Configure an authentication tunnel
 :icons: font
 :relative_path: ./authentication/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

If you have already configured a SMB server for a data SVM, you can use the `security login domain-tunnel create` command to configure the SVM as a gateway, or *tunnel*, for AD access to the cluster.

What you'll need

- You must have configured a SMB server for a data SVM.
- You must have enabled an AD domain user account to access the admin SVM for the cluster.
- You must be a cluster administrator to perform this task.

Beginning with ONTAP 9.10.1, if you have an SVM gateway (domain tunnel) for AD access, you can use Kerberos for admin authentication if you have disabled NTLM in your AD domain. In earlier releases, Kerberos was not supported with admin authentication for SVM gateways. This functionality is available by default; no configuration is required.

NOTE

Kerberos authentication is always attempted first. In case of failure, NTLM authentication is then attempted.

Step

1. Configure a SMB-enabled data SVM as an authentication tunnel for AD domain controller access to the cluster:

```
security login domain-tunnel create -vserver SVM_name
```

For complete command syntax, see the [worksheet](#).

The SVM must be running for the user to be authenticated.

The following command configures the SMB-enabled data SVMengData as an authentication tunnel.

```
cluster1::>security login domain-tunnel create -vserver engData
```

= Create an SVM computer account on the domain
:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

If you have not configured an SMB server for a data SVM, you can use the `vserver active-directory create` command to create a computer account for the SVM on the domain.

What you'll need

You must be a cluster or SVM administrator to perform this task.

About this task

After you enter the `vserver active-directory create` command, you are prompted to provide the credentials for an AD user account with sufficient privileges to add computers to the specified organizational unit in the domain. The password of the account cannot be empty.

Step

1. Create a computer account for an SVM on the AD domain:

```
vserver active-directory create -vserver SVM_name -account-name  
NetBIOS_account_name -domain domain -ou organizational_unit
```

For complete command syntax, see the [worksheet](#).

The following command creates a computer account named `ADSERVER1` on the domain `example.com` for the SVM `engData`. You are prompted to enter the AD user account credentials after you enter the command.

```
cluster1::>vserver active-directory create -vserver engData -account  
-name ADSERVER1 -domain example.com
```

In order to create an Active Directory machine account, you must supply the name and password of a Windows account with sufficient privileges to add computers to the "CN=Computers" container within the "example.com" domain.

Enter the user name: Administrator

Enter the password:

= Configure LDAP or NIS server access

= Configure LDAP or NIS server access overview

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

You must configure LDAP or NIS server access to an SVM before LDAP or NIS accounts can access the SVM. The switch feature lets you use LDAP or NIS as alternative name service sources.

= Configure LDAP server access

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

You must configure LDAP server access to an SVM before LDAP accounts can access the SVM. You can use the vserver services name-service ldap client create command to create an LDAP client configuration on the SVM. You can then use the vserver services name-service ldap create command to associate the LDAP client configuration with the SVM.

What you'll need

- You must have installed a [CA-signed server digital certificate](#) on the SVM.
- You must be a cluster or SVM administrator to perform this task.

About this task

Most LDAP servers can use the default schemas provided by ONTAP:

- MS-AD-BIS (the preferred schema for most Windows 2012 and later AD servers)
- AD-IDMU (Windows 2008, Windows 2012 and later AD servers)
- AD-SFU (Windows 2003 and earlier AD servers)
- RFC-2307 (UNIX LDAP servers)

It is best to use the default schemas unless there is a requirement to do otherwise. If so, you can create your own schema by copying a default schema and modifying the copy. For more information, see the following documents.

- NFS configuration
- NetApp Technical Report 4835: How to Configure LDAP in ONTAP

Steps

1. Create an LDAP client configuration on an SVM: `vserver services name-service ldap client create -vserver SVM_name -client-config client_configuration -servers LDAP_server_IPs -schema schema -use-start-tls true|false`

Start TLS is supported for access to data SVMs only. It is not supported for access to admin SVMs.

For complete command syntax, see the [worksheet](#).

The following command creates an LDAP client configuration named `corp` on the `SVMengData`. The client makes anonymous binds to the LDAP servers with the IP addresses `172.16.0.100` and `172.16.0.101`. The client uses the `RFC-2307` schema to make LDAP queries. Communication between the client and server is encrypted using Start TLS.

```
cluster1::>vserver services name-service ldap client create  
-vserver engData -client-config corp -servers  
172.16.0.100,172.16.0.101 -schema RFC-2307 -use-start-tls true
```

Beginning with ONTAP 9.2, the field `-ldap-servers` replaces the field `-servers`. This new field can take either a hostname or an IP address for the LDAP server.

2. Associate the LDAP client configuration with the SVM: `vserver services name-service ldap create -vserver SVM_name -client-config client_configuration -client -enabled true|false`

For complete command syntax, see the [worksheet](#).

The following command associates the LDAP client configuration `corp` with the `SVMengData`, and enables the LDAP client on the SVM.

```
cluster1::>vserver services name-service ldap create -vserver  
engData -client-config corp -client-enabled true
```

Beginning with ONTAP 9.2, the `vserver services name-service ldap create` command performs an automatic configuration validation and reports an error message if ONTAP is unable to contact the name server.

3. Validate the status of the name servers by using the `vserver services name-service ldap check` command.

The following command validates LDAP servers on the SVM vs0.

```
cluster1::> vserver services name-service ldap check -vserver vs0

| Vserver: vs0
| Client Configuration Name: c1
| LDAP Status: up
| LDAP Status Details: Successfully connected to LDAP server
"10.11.12.13".
```

The name service check command is available beginning with ONTAP 9.2.

= Configure NIS server access
:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You must configure NIS server access to an SVM before NIS accounts can access the SVM. You can use the `vserver services name-service nis-domain create` command to create an NIS domain configuration on an SVM.

What you'll need

- All configured servers must be available and accessible before you configure the NIS domain on the SVM.
- You must be a cluster or SVM administrator to perform this task.

About this task

You can create multiple NIS domains. Only one NIS domain can be set to `active` at a time.

Step

1. Create an NIS domain configuration on an SVM: `vserver services name-service nis-domain create -vserver SVM_name -domain client_configuration -active true|false -nis-servers NIS_server_IPs`

For complete command syntax, see the [worksheet](#).

Beginning with ONTAP 9.2, the field `-nis-servers` replaces the field `-servers`. This new field can take either a hostname or an IP address for the NIS server.

The following command creates an NIS domain configuration on the SVM engData. The NIS domain `nisdomain` is `active` on creation and communicates with an NIS server with the IP address 192.0.2.180.

```
cluster1::>vserver services name-service nis-domain create
-vserver engData -domain nisdomain -active true -nis-servers
192.0.2.180
```

= Create a name service switch
:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

The name service switch feature lets you use LDAP or NIS as alternative name service sources. You can use the vserver services name-service ns-switch modify command to specify the look-up order for name service sources.

What you'll need

- You must have configured LDAP and NIS server access.
- You must be a cluster administrator or SVM administrator to perform this task.

Step

1. Specify the lookup order for name service sources:

```
vserver services name-service ns-switch modify -vserver SVM_name -database  
name_service_switch_database -sources name_service_source_order
```

For complete command syntax, see the [worksheet](#).

The following command specifies the lookup order of the LDAP and NIS name service sources for the passwd database on the engDataSVM.

```
cluster1::>vserver services name-service ns-switch  
modify -vserver engData -database passwd -source files ldap,nis
```

= Change an administrator password
:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You should change your initial password immediately after logging into the system for the first time. If you are an SVM administrator, you can use the security login password command to change your own password. If you are a cluster administrator, you can use the security login password command to change any administrator's password.

What you'll need

- You must be a cluster or SVM administrator to change your own password.
- You must be a cluster administrator to change another administrator's password.

About this task

The new password must observe the following rules:

- It cannot contain the user name
- It must be at least eight characters long

- It must contain at least one letter and one number
- It cannot be the same as the last six passwords

You can use the security login role config modify command to modify the password rules for accounts associated with a given role. For more information, see the man page `security login role config modify`

Step

1. Change an administrator password: `security login password -vserver SVM_name -username user_name`

The following command changes the password of the administrator `admin1` for the `SVMvs1.example.com`. You are prompted to enter the current password, then enter and reenter the new password.

```
vs1.example.com::>security login password -vserver engData -username admin1
Please enter your current password:
Please enter a new password:
Please enter it again:
```

= Lock and unlock an administrator account

:icons: font

:relative_path: ./authentication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use the `security login lock` command to lock an administrator account, and the `security login unlock` command to unlock the account.

What you'll need

You must be a cluster administrator to perform these tasks.

Steps

1. Lock an administrator account:

```
security login lock -vserver SVM_name -username user_name
```

The following command locks the administrator account `admin1` for the SVM `vs1.example.com`:

```
cluster1::>security login lock -vserver engData -username admin1
```

2. Unlock an administrator account:

```
security login unlock -vserver SVM_name -username user_name
```

The following command unlocks the administrator account `admin1` for the SVM `vs1.example.com`:

```
cluster1::>security login unlock -vserver engData -username admin1
```

= Manage failed login attempts
:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Repeated failed login attempts sometimes indicate that an intruder is attempting to access the storage system. You can take a number of steps to ensure that an intrusion does not take place.

== How you will know that login attempts have failed

The Event Management System (EMS) notifies you about failed login attempts every hour. You can find a record of failed login attempts in the `audit.log` file.

== What to do if repeated login attempts fail

In the short term, you can take a number of steps to prevent an intrusion:

- Require that passwords be composed of a minimum number of uppercase characters, lowercase characters, special characters, and/or digits
- Impose a delay after a failed login attempt
- Limit the number of allowed failed login attempts, and lock out users after the specified number of failed attempts
- Expire and lock out accounts that are inactive for a specified number of days

You can use the `security login role config modify` command to perform these tasks.

Over the long term, you can take these additional steps:

- Use the `security ssh modify` command to limit the number of failed login attempts for all newly created SVMs.
- Migrate existing MD5-algorithm accounts to the more secure SHA-512 algorithm by requiring users to change their passwords.

= Enforce SHA-2 on administrator account passwords
:icons: font
:relative_path: ./authentication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Administrator accounts created prior to ONTAP 9.0 continue to use MD5 passwords after the upgrade, until the passwords are manually changed. MD5 is less secure than SHA-2. Therefore, after upgrading, you should prompt users of MD5 accounts to change their passwords to use the default SHA-512 hash function.

About this task

The password hash functionality enables you to do the following:

- Display user accounts that match the specified hash function.
- Expire accounts that use a specified hash function (for example, MD5), forcing the users to change their passwords in their next login.
- Lock accounts whose passwords use the specified hash function.
- When reverting to a release earlier than ONTAP 9, reset the cluster administrator's own password for it to be compatible with the hash function (MD5) that is supported by the earlier release.

ONTAP accepts pre-hashed SHA-2 passwords only by using NetApp Manageability SDK (security-login-create and security-login-modify-password).

Manageability enhancements

Steps

1. Migrate the MD5 administrator accounts to the SHA-512 password hash function:

a. Expire all MD5 administrator accounts: `security login expire-password -vserver * -username * -hash-function md5`

Doing so forces MD5 account users to change their passwords upon next login.

- b. Ask users of MD5 accounts to log in through a console or SSH session.

The system detects that the accounts are expired and prompts users to change their passwords. SHA-512 is used by default for the changed passwords.

2. For MD5 accounts whose users do not log in to change their passwords within a period of time, force the account migration:

a. Lock accounts that still use the MD5 hash function (advanced privilege level): `security login expire-password -vserver * -username * -hash-function md5 -lock-after integer`

After the number of days specified by `-lock-after`, users cannot access their MD5 accounts.

b. Unlock the accounts when the users are ready to change their passwords: `security login unlock -vserver vserver_name -username user_name`

c. Have users log in to their accounts through a console or SSH session and change their passwords when the system prompts them to do so.

= Ransomware protection

= Anti-ransomware overview

:toc: macro

:hardbreaks:

:toclevels: 1

:icons: font

:linkatrrs:

:relative_path: ./anti-ransomware/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

Beginning with ONTAP 9.10.1, the anti-ransomware feature uses workload analysis in NAS (NFS and SMB) environments to proactively detect and warn about abnormal activity that might indicate a ransomware attack.

When an attack is suspected, anti-ransomware also creates new Snapshot backups, in addition to existing protection from scheduled Snapshot copies.

The anti-ransomware feature requires the Multi-tenant Encryption Key Management (MT_EK_MGMT) license, which is available in the security and compliance bundle.

== ONTAP ransomware protection strategy

An effective ransomware detection strategy should include more than a single layer of protection.

An analogy would be the safety features of a vehicle. You wouldn't want to rely on a single feature, such as a seatbelt, to completely protect you in an accident. Air bags, anti-lock brakes, and forward-collision warning are all additional safety features that will lead to a much better outcome. Ransomware protection should be viewed in the same way.

While ONTAP includes features like FPolicy, Snapshot copies, SnapLock, and Active IQ Digital Advisor to help protect from ransomware, the following information focuses on the ONTAP anti-ransomware on-box feature with machine-learning capabilities.

To learn more about ONTAP's other anti-ransomware features, see: [TR-4572: NetApp Solution for Ransomware](#).

== What ONTAP anti-ransomware detects

There are two types of ransomware attacks:

1. Denial of service to files by encrypting data.
The attacker withholds access to this data unless a ransom is paid.
2. Theft of sensitive proprietary data.
The attacker threatens to release this data to the public domain unless a ransom is paid.

ONTAP ransomware protection addresses the first type, with an anti-ransomware detection mechanism that is based on:

1. Identification of the incoming data as encrypted or plaintext.
2. Analytics, which detects
 - High data *entropy* (an evaluation of the randomness of data in a file)
 - A surge in abnormal volume activity with data encryption
 - An extension that does not conform to the normal extension type

No ransomware detection or prevention system can completely guarantee safety from a ransomware attack. While it's possible an attack might go undetected, NetApp ransomware protection acts as an important additional layer of defense if anti-virus software has failed to detect an intrusion. Anti-ransomware can detect the spread of most ransomware attacks after only a small number of files are encrypted, take action automatically to protect data, and alert you that a suspected attack is happening.

== How to recover data in ONTAP after a ransomware attack

When an attack is suspected, the system takes a volume Snapshot copy at that point in time and locks that copy. If the attack is confirmed later, the volume can be restored to this proactively taken snapshot, minimizing the data loss.

Locked Snapshot copies cannot be deleted by normal means. However, if you decide later to mark the attack as a false positive, the locked copy will be deleted.

With the knowledge of the affected files and the time of attack, it is possible to selectively recover the affected files from various Snapshot copies, rather than simply reverting the whole volume to one of the snapshots.

Anti-ransomware thus builds on proven ONTAP data protection and disaster recovery technology to respond to ransomware attacks. See the following topics for more information on recovering data.

- [Recover from Snapshot copies \(System Manager\)](#)
- [Restoring files from Snapshot copies \(CLI\)](#)
- [Smart ransomware recovery](#)

= Anti-ransomware use cases and considerations

:toc: macro
:hardbreaks:
:toclevels: 1
:icons: font
:linkatrrs:
:relative_path: ./anti-ransomware/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

In the current release, ransomware protection is most suitable in NAS environments. Support for other environments will be available in future releases.

Suitable workloads:

- Databases on NFS storage
- Windows or Linux home directories

Because users could create files with extensions that weren't detected in the learning period, there is greater possibility of false positives in this workload.

- Images and video

For example, health care records and Electronic Design Automation (EDA) data.

Unsuitable workloads:

- Workloads with a high frequency of file create or delete (hundreds of thousands of files in few seconds; for example, test/dev workloads)
- The anti-ransomware feature depends on the ability to recognize an unusual surge in file create or delete activity. If the application itself is the source of the file activity, it cannot be effectively distinguished from ransomware activity
- Workloads where the application or the host encrypts data
The anti-ransomware feature depends on distinguishing incoming data as encrypted or unencrypted. If the application itself is encrypting the data, then the effectiveness of the feature is reduced. However, the feature can still work based on file activity (create, delete, and overwrite) and file type.

Unsupported system configurations:

- SAN environments
- ONTAP S3 environments
- VMDKs on NFS
- Cloud Volumes ONTAP
- Cloud Volume Services for AWS and Google Cloud
- Azure NetApp Files
- Amazon FSx for ONTAP
- ONTAP Select

Volume requirements:

- Less than 100% full
- Junction path must be active

Unsupported volume types:

- offline volumes
- restricted volumes
- Snaplock volumes
- SnapLock volumes
- FlexGroup volumes
- FlexCache volumes
- SAN-only volumes
- volumes of stopped storage VMs
- root volumes of storage VMs
- data protection volumes

== Anti-ransomware performance and frequency considerations

The anti-ransomware feature can have a minimal impact on system performance as measured in throughput and peak IOPS. The impact of the anti-ransomware feature is highly dependent on volume workloads. For most typical or common workloads, the following configuration limits are recommended:

- No more than 50 volumes per node if the workload is either read-intensive or the data can be compressed.
- No more than 20 volumes per node if the workload is write-intensive and the data cannot be compressed.

Because anti-ransomware analytics are run in a prioritized sequence, as the number of protected volumes increases, analytics are run on each volume less frequently.

= Enable anti-ransomware

:toc: macro

:hardbreaks:

:toclevels: 1

:icons: font

:linkatrs:

```
:relative_path: ./anti-ransomware/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/
```

Anti-ransomware can be enabled on new or existing volumes. You first enable anti-ransomware in learning mode, in which the system analyzes the workload to characterize normal behavior, then you switch to active mode, in which abnormal activity is flagged for your evaluation.

What you'll need

- A storage VM enabled for NFS or SMB (or both).
- The Multi-tenant Encryption Key Management (MT_EK_MGMT) license installed from the security and compliance bundle.
- An NAS workload with clients configured.
- The volume to be protected must have an active junction-path.
- Optional but recommended: The EMS system is configured to send email notifications, which will include notices of anti-ransomware activity. For more information, see [Configure EMS events to send email notifications](#).

About this task

The NetApp anti-ransomware feature includes an initial learning period (also known as “dry run”), in which an ONTAP system learns which file extensions are valid and uses the analyzed data to develop alert profiles. After running anti-ransomware in learning mode for enough time to assess workload characteristics, you can switch to active mode and start protecting your data. Anti-ransomware continues to collect and analyze data to refine alert profiles.

During the learning period, the system automatically learns the workload characteristics of a configured volume, performing special observations and pattern analysis.

A learning period of 30 days is recommended. Although you can switch from learning to active mode anytime, switching early may lead to too many false positives.

In the ONTAP CLI, you can use the security anti-ransomware volume workload-behavior show command to show file extensions detected to date. However, it is recommended that you not use this tool to shorten the learning period.

You can enable ransomware protection on an existing volume, or you can create a new volume and enable ransomware protection from the beginning.

In existing volumes, learning and active modes only apply to newly-written data, not to already existing data in the volume. The existing data is not scanned and analyzed, because the characteristics of earlier normal data traffic are assumed based on the new data after the volume is enabled for the anti-ransomware feature.

In the ONTAP CLI, a new command family has been introduced to manage this feature: `security anti-ransomware volume`. You can also use the `volume modify` command with the `-anti-ransomware` parameter to manage the feature.

== System Manager procedure

1. Click **Storage > Volumes** and then select the volume you want to protect.

2. In the Security tab of the Volumes overview, click **Status** to switch from Disabled to Enabled in learning-mode in the Anti-ransomware box.
3. When the learning period is over, switch anti-ransomware to active mode.
 - a. Click **Storage > Volumes** and then select the volume that is ready for active mode.
 - b. In the Security tab of the Volumes overview, click **Switch** to active mode in the Anti-ransomware box.
4. You can always verify the anti-ransomware state of the volume in the Anti-ransomware box.
To display anti-ransomware status for all volumes: In the Volumes pane, click **Show/Hide**, then ensure that Anti-ransomware status is checked.

== CLI procedure

1. Modify an existing volume to enable ransomware protection in learning mode:

```
security anti-ransomware volume dry-run -volume vol_name -vserver svm_name
```

You can also enable ransomware with the `volume modify` command:

```
volume modify -volume vol_name -vserver svm_name -anti-ransomware-state
dry-run
```

At the CLI, you can also create a new volume with anti-ransomware protection enabled before provisioning data.

```
volume create -volume vol_name -vserver svm_name -aggregate aggr_name -size
nn -anti-ransomware-state dry-run -junction-path /path_name
```

You should always enable ransomware initially in the dry-run state. Beginning with the active state can lead to excessive false positive reports.

2. When the learning period is over, modify the protected volume to switch to active mode:

```
security anti-ransomware volume enable -volume vol_name -vserver svm_name
```

You can also switch to active mode with the `modify volume` command:

```
volume modify -volume vol_name -vserver svm_name -anti-ransomware-state
active
```

3. Verify the anti-ransomware state of the volume.

```
security anti-ransomware volume show
```

= Enable anti-ransomware by default in new volumes

:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./anti-ransomware/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Beginning with ONTAP 9.10.1, you can configure storage VMs (SVMs) such that new volumes are enabled by default for anti-ransomware in learning mode.

What you'll need

- The Multi-tenant Encryption Key Management (MT_EK_MGMT) license installed from the security and compliance bundle.

About this task

New volumes are created by default with anti-ransomware in disabled mode, but you can change this setting in System Manager and at the CLI. Volumes enabled by default are set to anti-ransomware in learning mode.

== System Manager procedure

1. Click **Storage > Storage VMs** and then select the storage VM for default anti-virus.
2. In the **Settings** tab, [in the **Security** section], click  in the **Anti-ransomware** box, then check the box to enable anti-ransomware for NAS volumes.

== CLI procedure

1. Modify an existing SVM to enable anti-ransomware by default in new volumes:

```
vserver modify -vserver svm_name -anti-ransomware-default-volume-state dry-run
```

At the CLI, you can also create a new SVM with anti-ransomware enabled by default for new volumes.

```
vserver create -vserver svm_name -anti-ransomware-default-volume-state dry-run [other parameters as needed]
```

= Pause anti-ransomware to exclude workload events from analysis

:toc: macro

:hardbreaks:

:toclevels: 1

:icons: font

:linkatrrs:

:relative_path: ./anti-ransomware/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

If you are expecting unusual workload events, you can temporarily suspend and resume anti-ransomware analysis at any time.

What you'll need

- Anti-ransomware is running in learning or active mode.

About this task

During an anti-ransomware pause, no events are logged nor are any actions for new writes. However, the analytics operation continues for earlier logs in the background.

Do not use the anti-ransomware disable function to pause analytics. Doing so disables anti-ransomware on the volume and all the existing information around learned workload behavior is lost. This would require a restart of the learning period.

== System Manager procedure

1. Click **Storage > Volumes** and then select the volume where you want to pause anti-ransomware.
2. In the Security tab of the Volumes overview, click **Pause anti-ransomware** in the Anti-ransomware box.

== CLI procedure

Pause ransomware protection on a volume:

```
security anti-ransomware volume pause -vserver svm_name -volume vol_name
```

To resume processing, use the resume parameter.

```
security anti-ransomware volume resume -vserver svm_name -volume vol_name
```

= Respond to abnormal activity.

:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./anti-ransomware/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

When anti-ransomware detects abnormal activity in a protected volume, it issues a warning. You should evaluate the notification to determine whether the activity is expected and acceptable, or whether an attack is under way.

What you'll need

- Anti-ransomware is running in active mode.

About this task

Anti-ransomware displays a list of suspected files when it detects any combination of high data entropy, abnormal volume activity with data encryption, and unusual file extensions.

When the warning is issued, you can respond by marking the file activity in one of two ways:

- False positive

The identified file type is expected in your workload and can be ignored.

- Potential ransomware attack

The identified file type is unexpected in your workload and should be treated as a potential attack.

In both cases, normal monitoring resumes after updating and clearing the notices; anti-ransomware records your evaluation, logs are updated with the new file types and using them for future analysis. However, in the case of a suspected attack, you must determine whether it is an attack, respond to it if it is, and restore protected data before clearing the notices. For more information, see [How to recover from a ransomware attack](#).

== System Manager procedure

1. When you receive an “abnormal activity” notification, click on the link or navigate to the **Security** tab of the **Volumes** overview.

Warnings are displayed in the Overview pane of the Events window.

2. When a “Detected abnormal volume activity” message is displayed, view the suspect files.

In the **Security** tab, click **View Suspected File Types**.

3. In the **Suspected File Types** dialog box, examine each file type and mark it as either “False Positive” or “Potential Ransomware attack”.

If you selected this value...	Take this action...
False Positive	Click Update and Clear Suspect File Types to record your decision and resume normal anti-ransomware monitoring.
Potential Ransomware Attack	Respond to the attack and restore protected data. Then click Update and Clear Suspect File Types to record your decision and resume normal anti-ransomware monitoring.

== CLI procedure

1. When you receive a notification of a suspected ransomware attack, verify the time and severity of the attack:

```
security anti-ransomware volume show -vserver svm_name -volume vol_name
```

Sample output:

```
Vserver Name: vs0
Volume Name: vol1
State: enabled
Attack Probability: moderate
Attack Timeline: 9/14/2021 01:03:23
Number of Attacks: 1
```

You can also check EMS messages:

```
event log show -message-name callhome.arw.activity.seen
```

2. Generate an attack report and note the output location:

```
security anti-ransomware volume attack generate-report -volume vol_name
-dest-path file_location/
```

Sample output:

```
Report "report_file_vs0_vol1_14-09-2021_01-21-08" available at path
"vs0:vol1/"
```

3. View the report on an admin client system. For example:

```
[root@rhel8 mnt]# cat report_file_vs0_vol1_14-09-2021_01-21-08  
19 "9/14/2021 01:03:23" test_dir_1/test_file_1.jpg.lckd  
20 "9/14/2021 01:03:46" test_dir_2/test_file_2.jpg.lckd  
21 "9/14/2021 01:03:46" test_dir_3/test_file_3.png.lckd`
```

4. Take one of the following actions based on your evaluation of the file extensions:

- False positive

Enter the following command to record your decision – adding the new extension to the list of those allowed – and resume normal anti-ransomware monitoring:

```
anti-ransomware volume attack clear-suspect -vserver svm_name -volume vol_name [extension identifiers] -false-positive true
```

Use one of the following parameters to identify the extensions:

[-seq-no integer] Sequence number of the file in the suspect list.

[-extension text, ...] File extensions

[-start-time date_time -end-time date_time] Starting and ending times for the range of files to be cleared, in the form "MM/DD/YYYY HH:MM:SS".

- Potential ransomware attack

Respond to the attack and restore data. Then enter the following command to record your decision and resume normal anti-ransomware monitoring:

```
anti-ransomware volume attack clear-suspect -vserver svm_name -volume vol_name [extension identifiers] -false-positive false
```

Use one of the following parameters to identify the extensions:

[-seq-no integer] Sequence number of the file in the suspect list

[-extension text, ...] File extension

[-start-time date_time -end-time date_time] Starting and ending times for the range of files to be cleared, in the form "MM/DD/YYYY HH:MM:SS".

= Restore data after an attack

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./anti-ransomware/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

Snapshot copies named “Anti_ransomware_backup” are created when anti-ransomware detects a potential attack. You can restore data from these anti-ransomware copies or other Snapshot copies.

If a ransomware attack occurs, you should contact NetApp Support to see if they can assist with data recovery.

What you'll need

- Anti-ransomware enabled
- Reports from potential ransomware attacks

== System Manager procedure

1. Display the Snapshot copies in volumes identified in a potential attack:
Click **Storage > Volumes**, select the volume, then click the Snapshot Copies tab.
2. Restore the desired copies according to these instructions:
[Recover from Snapshot copies](#)

== CLI procedure

1. Display the Snapshot copies in volumes identified in a potential attack:
`volume snapshot show -vserver svm_name -volume vol_name`
2. Restore the desired copies according to these instructions:
[Restoring files from Snapshot copies](#)

= Antivirus configuration

= Antivirus configuration overview

:icons: font

:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use NetApp virus scanning, called *Vscan*, to protect data from being compromised by viruses or other malicious code. It shows you how to use on-access scanning to check for viruses when clients access files over SMB, and how to use on-demand scanning to check for viruses immediately or on a schedule.

You can work with *Vscan* by using the ONTAP command-line interface (CLI), not System Manager or an automated scripting tool. *Vscan* is not supported by System Manager.

= About NetApp antivirus protection

= About NetApp virus scanning

:icons: font

:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use integrated antivirus functionality on NetApp storage systems to protect

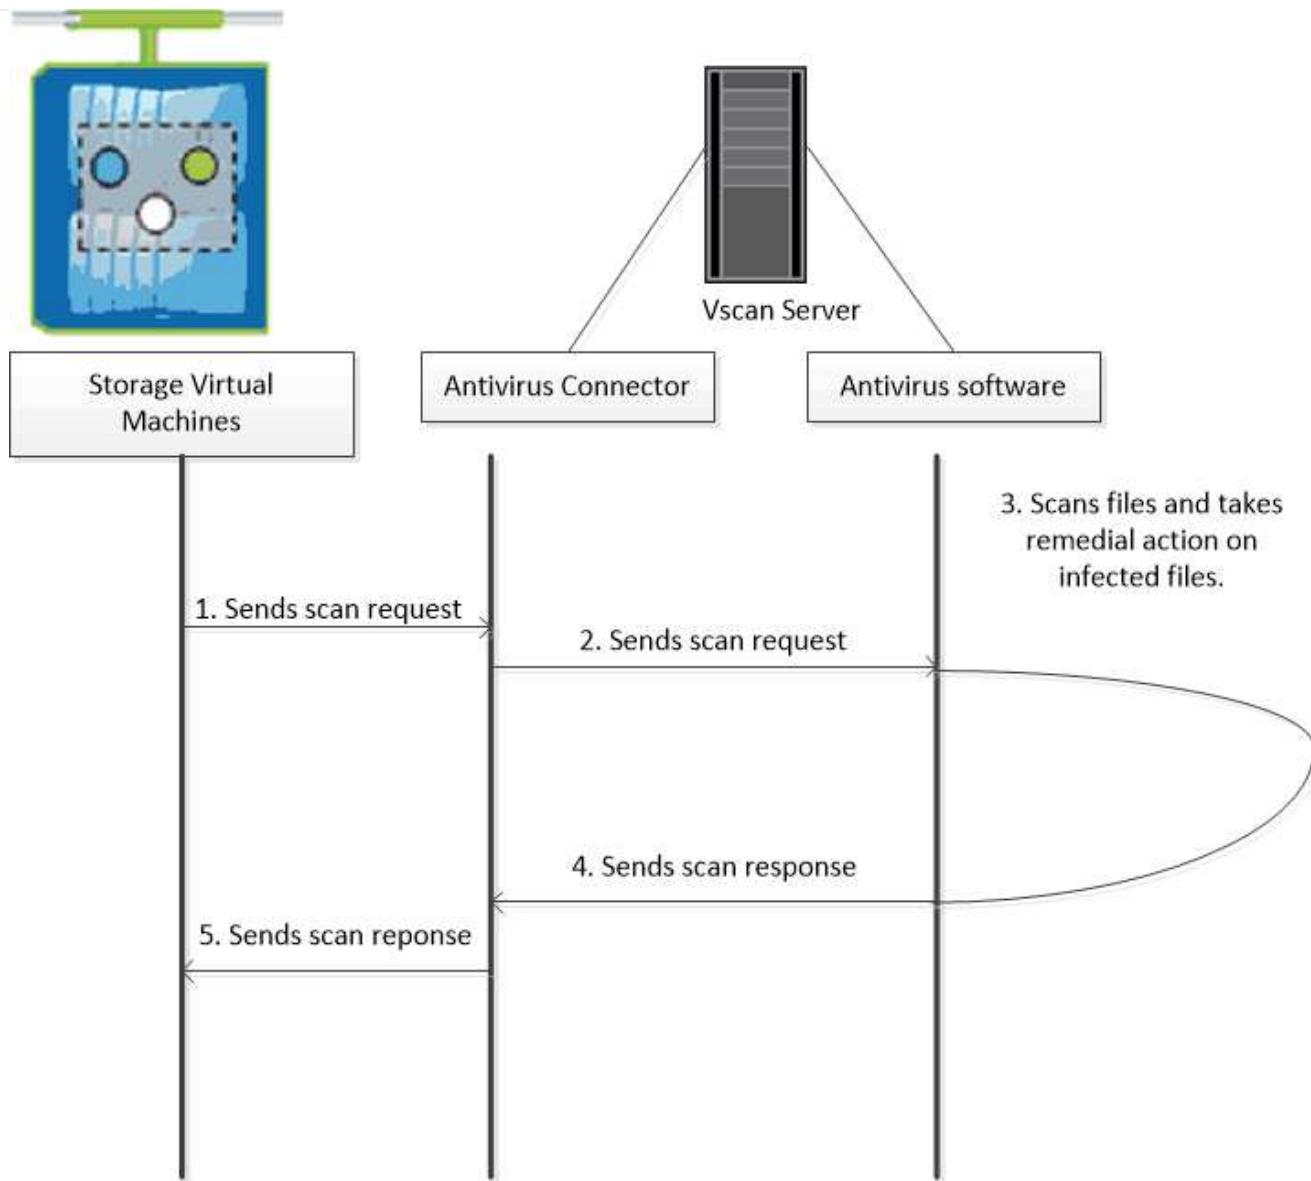

data from being compromised by viruses or other malicious code. NetApp virus scanning, called *Vscan*, combines best-in-class third-party antivirus software with ONTAP features that give you the flexibility you need to control which files get scanned and when.

== How virus scanning works

Storage systems offload scanning operations to external servers hosting antivirus software from third-party vendors. The ONTAP Antivirus Connector, provided by NetApp and installed on the external server, handles communication between the storage system and the antivirus software.

- You can use *on-access scanning* to check for viruses when clients open, read, rename, or close files over SMB. File operation is suspended until the external server reports the scan status of the file. If the file has already been scanned, ONTAP allows the file operation. Otherwise, it requests a scan from the server.
- You can use *on-demand scanning* to check files for viruses immediately or on a schedule. You might want to run scans only in off-peak hours, for example. The external server updates the scan status of the checked files, so that file-access latency for those files (assuming they have not been modified) is typically reduced when they are next accessed over SMB. You can use on-demand scanning for any path in the SVM namespace, even for volumes that are exported only through NFS.

You typically enable both scanning modes on an SVM. In either mode, the antivirus software takes remedial action on infected files based on your settings in the software.

= Virus scanning workflow

:icons: font

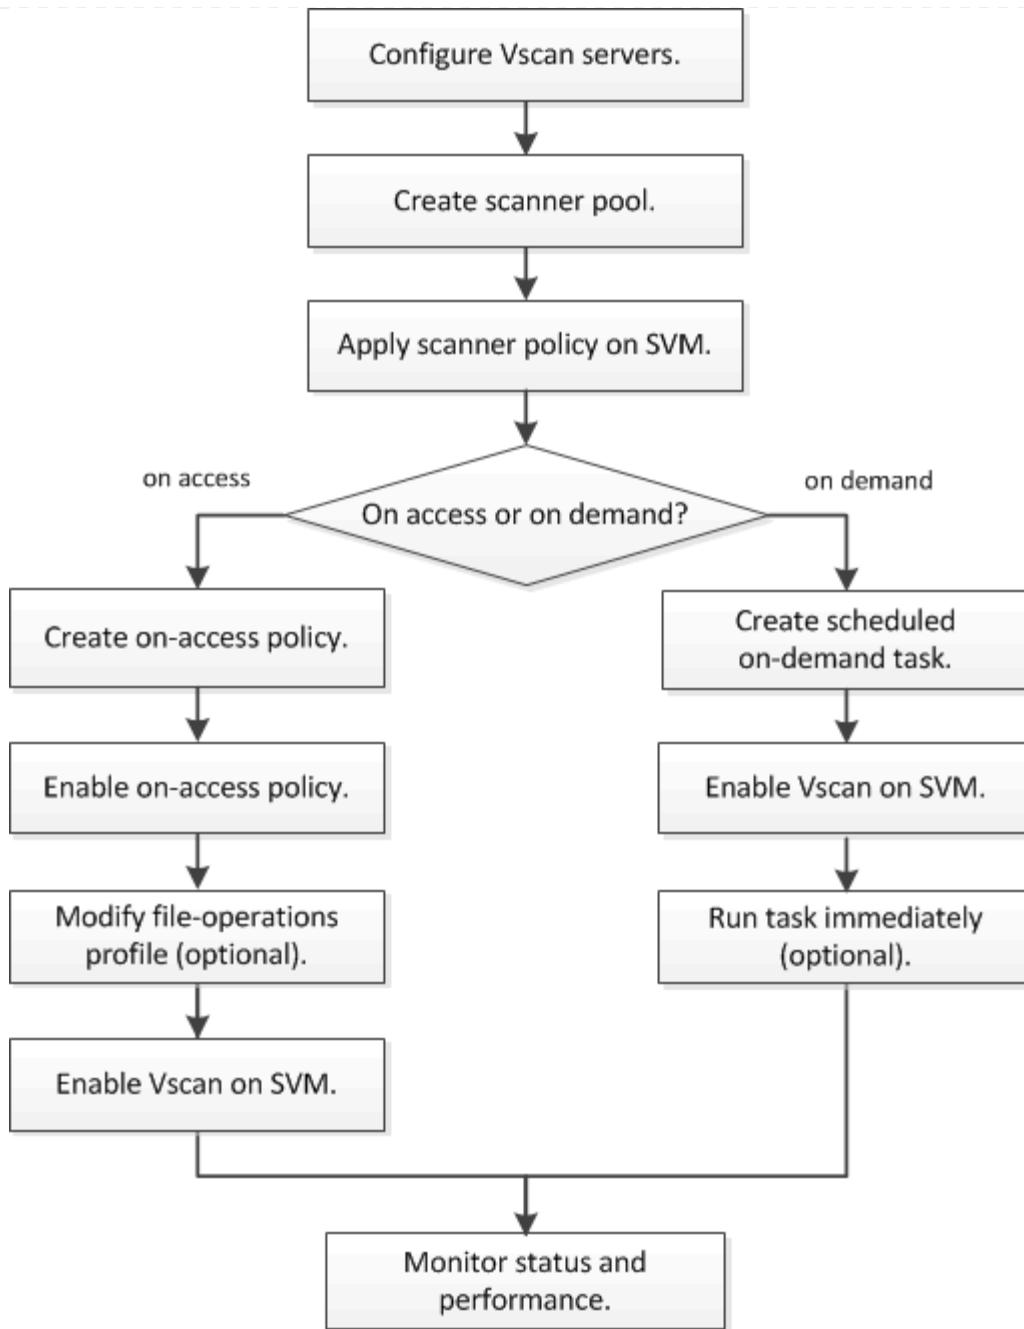

:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You must create a scanner pool and apply a scanner policy before you can enable scanning. You typically enable both on-access and on-demand scanning on an SVM.

You must have completed the CIFS configuration.

= Antivirus architecture

:icons: font

:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

The NetApp antivirus architecture consists of a Vscan server and a set of ONTAP configurables.

== Vscan server components

You must install the following components on the Vscan server.

- **ONTAP Antivirus Connector**

The ONTAP Antivirus Connector provided by NetApp handles communication between ONTAP and

the Vscan server.

- **Antivirus software**

ONTAP-compliant third-party antivirus software scans files for viruses or other malicious code. You specify the remedial actions to be taken on infected files when you configure the software.

== ONTAP configurables

You must configure the following items on the NetApp storage system.

- **Scanner pool**

A scanner pool defines the Vscan servers and privileged users that can connect to SVMs. It also defines a scan request timeout period, after which the scan request is sent to an alternative Vscan server if one is available.

It is a best practice to set the timeout period in the antivirus software on the Vscan server to five seconds less than the scanner-pool request timeout period, to avoid situations in which file access is delayed or denied altogether because the timeout period on the software is greater than the timeout period for the scan request.

- **Privileged user**

A privileged user is a domain user account that a Vscan server uses to connect to the SVM. The account must be included in the list of privileged users defined in the scanner pool.

- **Scanner policy**

A scanner policy determines whether a scanner pool is active. A scanner policy can have one of the following values:

- Primary specifies that the scanner pool is active.
 - Secondary specifies that the scanner pool is active only if none of the Vscan servers in the primary scanner pool is connected.
 - Idle specifies that the scanner pool is inactive.
- Scanner policies are system-defined. You cannot create a custom scanner policy.

- **On-access policy**

An on-access policy defines the scope of an on-access scan. You can specify the maximum size of the files to be scanned, the extensions of the files to be included in the scan, and the extensions and paths of the files to be excluded from the scan.

By default, only read-write volumes are scanned. You can specify filters that enable scanning of read-only volumes or that restrict scanning to files opened with execute access:

- `scan-ro-volume` enables scanning of read-only volumes.
- `scan-execute-access` restricts scanning to files opened with execute access.

“Execute access” is not identical with “execute permission.” A given client will have “execute access” on an executable file only if the file was opened with “execute intent.”

You can set the `scan-mandatory` option to off to specify that file access is allowed when no Vscan servers are available for virus scanning.

- **On-demand task**

An on-demand task defines the scope of an on-demand scan. You can specify the maximum size of the files to be scanned, the extensions and paths of the files to be included in the scan, and the extensions and paths of the files to be excluded from the scan. Files in subdirectories are scanned by default.

You use a cron schedule to specify when the task runs. You can use the `vserver vscan on-demand-task run` command to run the task immediately.

- **Vscan file-operations profile (on-access scanning only)**

The `-vscan-fileop-profile` parameter for the `vserver cifs share create` command defines which operations on a SMB share can trigger virus scanning. By default, the parameter is set to `standard`, which is the NetApp best practice.

You can adjust this parameter as necessary when you create or modify a SMB share:

- `no-scan` specifies that virus scans are never triggered for the share.
- `standard` specifies that virus scans can be triggered by open, close, and rename operations.
- `strict` specifies that virus scans can be triggered by open, read, close, and rename operations.

The `strict` profile provides enhanced security for situations in which multiple clients access a file simultaneously. If one client closes a file after writing a virus to it, and the same file remains open on a second client, `strict` ensures that a read operation on the second client triggers a scan before the file is closed.

You should be careful to restrict the `strict` profile to shares containing files that you anticipate will be accessed simultaneously. Because the profile generates more scan requests than the others, it may affect performance adversely.

- `writes-only` specifies that virus scans can be triggered only when a file that has been modified is closed.

If a client application performs a rename operation, the file is closed with the new name and is not scanned. If such operations pose a security concern in your environment, you should use the `standard` or `strict` profile.

Because `writes-only` generates fewer scan requests than the other profiles (except `no-scan`), it typically improves performance.

Keep in mind, though, that if you use this profile for a share, the scanner must be configured to delete or quarantine an unrepairable infected file, so that it cannot be accessed by clients later. If, for example, a client closes a file after writing a virus to it, and the file is not repaired, deleted, or quarantined, any client that accesses the file *without* writing to it will be infected.

= Vscan server installation and configuration
:icons: font
:relative_path: ./antivirus/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You must set up one or more Vscan servers to ensure that files on your system are scanned for viruses. Follow the instructions provided by your vendor to install and configure the antivirus software on the server. Follow the instructions in the readme file provided by NetApp to install and configure the ONTAP Antivirus Connector.

For disaster recovery and MetroCluster configurations, you must set up separate Vscan servers for the local and partner clusters.

== Antivirus software requirements

- For information about antivirus software requirements, see the vendor documentation.
- For information about the vendors, software, and versions supported by Vscan, see the NetApp Interoperability Matrix.

mysupport.netapp.com/matrix

== ONTAP Antivirus Connector requirements

- You can download the ONTAP Antivirus Connector from the Software Download page on the NetApp Support Site. [NetApp Downloads: Software](#)
- For information about the Windows versions supported by the ONTAP Antivirus Connector, see the NetApp Interoperability Matrix.

mysupport.netapp.com/matrix

You can install different versions of Windows servers for different Vscan servers in a cluster.

- .NET 3.0 or later must be installed on the Windows server.
- SMB 2.0 must be enabled on the Windows server.

= Configure scanner pools

= Configure scanner pools overview

:icons: font
:relative_path: ./antivirus/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

A scanner pool defines the Vscan servers and privileged users that can connect to SVMs. A scanner policy determines whether a scanner pool is active.

If you use an export policy on a SMB server, you must add each Vscan server to the export policy.

= Create a scanner pool on a single cluster

```
:icons: font
:relative_path: ./antivirus/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

A scanner pool defines the Vscan servers and privileged users that can connect to SVMs. You can create a scanner pool for an individual SVM or for all of the SVMs in a cluster.

What you'll need

- SVMs and Vscan servers must be in the same domain or in trusted domains.
- For scanner pools defined for an individual SVM, you must have configured the ONTAP Antivirus Connector with the SVM management LIF or the SVM data LIF.
- For scanner pools defined for all of the SVMs in a cluster, you must have configured the ONTAP Antivirus Connector with the cluster management LIF.

About this task

The list of privileged users must include the domain user account the Vscan server uses to connect to the SVM.

Steps

1. Create a scanner pool:

```
vserver vscan scanner-pool create -vserver data_SVM|cluster_admin_SVM
-scanner-pool scanner_pool -hostnames Vscan_server_hostnames -privileged-
-users privileged_users
```

- Specify a data SVM for a pool defined for an individual SVM, and specify a cluster admin SVM for a pool defined for all of the SVMs in a cluster.
- Specify an IP address or FQDN for each Vscan server host name.
- Specify the domain and user name for each privileged user.
For a complete list of options, see the man page for the command.

The following command creates a scanner pool named SP on the vs1SVM:

```
cluster1::> vserver vscan scanner-pool create -vserver vs1 -scanner
-pool SP -hostnames 1.1.1.1,vmwin204-27.fsct.nb -privileged-users
cifs\u1,cifs\u2
```

2. Verify that the scanner pool was created: `vserver vscan scanner-pool show -vserver data_SVM|cluster_admin_SVM -scanner-pool scanner_pool`

For a complete list of options, see the man page for the command.

The following command displays the details for the SP scanner pool:

```

cluster1::> vserver vscan scanner-pool show -vserver vs1 -scanner
-pool SP

          Vserver: vs1
          Scanner Pool: SP
          Applied Policy: idle
          Current Status: off
          Cluster on Which Policy Is Applied: -
          Scanner Pool Config Owner: vserver
          List of IPs of Allowed Vscan Servers: 1.1.1.1, 10.72.204.27
          List of Host Names of Allowed Vscan Servers: 1.1.1.1, vmwin204-
27.fsct.nb
          List of Privileged Users: cifs\u1, cifs\u2

```

You can also use the `vserver vscan scanner-pool show` command to view all of the scanner pools on an SVM. For complete command syntax, see the man page for the command.

= Create scanner pools in MetroCluster configurations
:icons: font
:relative_path: ./antivirus/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You must create primary and secondary scanner pools on each cluster in a MetroCluster configuration, corresponding to the primary and secondary SVMs on the cluster.

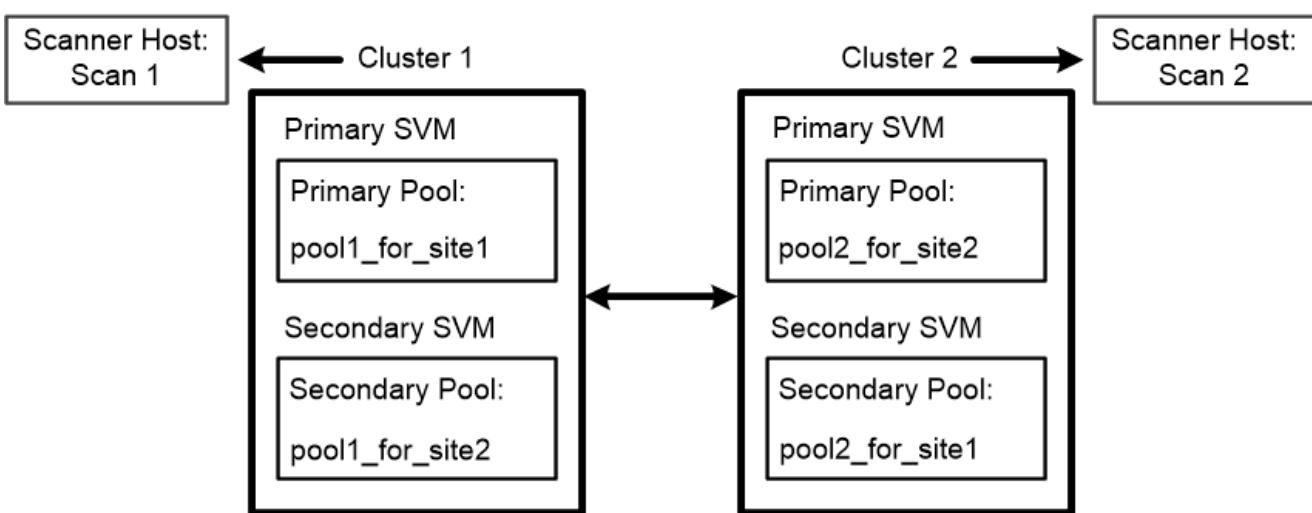

What you'll need

- SVMs and Vscan servers must be in the same domain or in trusted domains.
- For scanner pools defined for an individual SVM, you must have configured the ONTAP Antivirus Connector with the SVM management LIF or the SVM data LIF.
- For scanner pools defined for all of the SVMs in a cluster, you must have configured the ONTAP Antivirus Connector with the cluster management LIF.

About this task

MetroCluster configurations protect data by implementing two physically separate mirrored clusters. Each cluster synchronously replicates the data and SVM configuration of the other. A primary SVM on the local cluster serves data when the cluster is online. A secondary SVM on the local cluster serves data when the remote cluster is offline.

This means that you must create primary and secondary scanner pools on each cluster in a MetroCluster configuration, corresponding to the primary and secondary SVMs on the cluster. The secondary pool becomes active when the cluster begins serving data from the secondary SVM. The following illustration shows a typical MetroCluster configuration.

i The list of privileged users must include the domain user account the Vscan server uses to connect to the SVM.

Steps

1. Create a scanner pool:

```
vserver vscan scanner-pool create -vserver data_SVM|cluster_admin_SVM  
-scanner-pool scanner_pool -hostnames Vscan_server_hostnames -privileged  
-users privileged_users
```

- Specify a data SVM for a pool defined for an individual SVM, and specify a cluster admin SVM for a pool defined for all the SVMs in a cluster.
- Specify an IP address or FQDN for each Vscan server host name.
- Specify the domain and user name for each privileged user.

i You must create all scanner pools from the cluster containing the primary SVM.

For a complete list of options, see the man page for the command.

The following commands create primary and secondary scanner pools on each cluster in a MetroCluster configuration:

```

cluster1::> vserver vscan scanner-pool create -vserver cifssvm1 -
scanner-pool pool1_for_site1 -hostnames scan1 -privileged-users cifs
\u1,cifs\u2

cluster1::> vserver vscan scanner-pool create -vserver cifssvm1 -
scanner-pool pool1_for_site2 -hostnames scan1 -privileged-users cifs
\u1,cifs\u2

cluster1::> vserver vscan scanner-pool create -vserver cifssvm1 -
scanner-pool pool2_for_site1 -hostnames scan2 -privileged-users cifs
\u1,cifs\u2

cluster1::> vserver vscan scanner-pool create -vserver cifssvm1 -
scanner-pool pool2_for_site2 -hostnames scan2 -privileged-users cifs
\u1,cifs\u2

```

- Verify that the scanner pools were created: `vserver vscan scanner-pool show -vserver data_SVM|cluster_admin_SVM -scanner-pool scanner_pool`

For a complete list of options, see the man page for the command.

The following command displays the details for the scanner pool pool1:

```

cluster1::> vserver vscan scanner-pool show -vserver cifssvm1
-scanner-pool pool1_for_site1

Vserver: cifssvm1
Scanner Pool: pool1_for_site1
Applied Policy: idle
Current Status: off
Cluster on Which Policy Is Applied: -
Scanner Pool Config Owner: vserver
List of IPs of Allowed Vscan Servers:
List of Host Names of Allowed Vscan Servers: scan1
List of Privileged Users: cifs\u1,cifs\u2

```

You can also use the `vserver vscan scanner-pool show` command to view all of the scanner pools on an SVM. For complete command syntax, see the man page for the command.

= Apply a scanner policy on a single cluster
:icons: font
:relative_path: ./antivirus/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

A scanner policy determines whether a scanner pool is active. You must make a

scanner pool active before the Vscan servers that are defined in the scanner pool can connect to an SVM.

About this task

- You can apply only one scanner policy to a scanner pool.
- If you created a scanner pool for all of the SVMs in a cluster, you must apply a scanner policy on each SVM individually.
- For disaster recovery and MetroCluster configurations, you must apply a scanner policy to the scanner pools for the local cluster and partner cluster.

In the policy that you create for the local cluster, you must specify the local cluster in the `cluster` parameter. In the policy that you create for the partner cluster, you must specify the partner cluster in the `cluster` parameter. The partner cluster can then take over virus scanning operations in case of a disaster.

Steps

1. Apply a scanner policy:

```
vserver vscan scanner-pool apply-policy -vserver data_SVM -scanner-pool  
scanner_pool -scanner-policy primary|secondary|idle -cluster  
cluster_to_apply_policy_on
```

A scanner policy can have one of the following values:

- Primary specifies that the scanner pool is active.
- Secondary specifies that the scanner pool is active only if none of the Vscan servers in the primary scanner pool are connected.
- Idle specifies that the scanner pool is inactive.

The following example shows that the scanner pool named SP on the vs1 SVM is active:

```
cluster1::> vserver vscan scanner-pool apply-policy -vserver vs1  
-scanner-pool SP -scanner-policy primary
```

2. Verify that the scanner pool is active:

```
vserver vscan scanner-pool show -vserver data_SVM|cluster_admin_SVM  
-scanner-pool scanner_pool
```

For a complete list of options, see the man page for the command.

The following command displays the details for the SP scanner pool:

```
cluster1::> vserver vscan scanner-pool show -vserver vs1 -scanner
-pool SP

          Vserver: vs1
          Scanner Pool: SP
          Applied Policy: primary
          Current Status: on
          Cluster on Which Policy Is Applied: cluster1
          Scanner Pool Config Owner: vserver
          List of IPs of Allowed Vscan Servers: 1.1.1.1, 10.72.204.27
          List of Host Names of Allowed Vscan Servers: 1.1.1.1, vmwin204-
27.fsct.nb
          List of Privileged Users: cifs\u1, cifs\u2
```

You can use the `vserver vscan scanner-pool show-active` command to view the active scanner pools on an SVM. For the complete command syntax, see the man page for the command.

= Apply scanner policies in MetroCluster configurations
:icons: font
:relative_path: ./antivirus/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

A scanner policy determines whether a scanner pool is active. You must apply a scanner policy to the primary and secondary scanner pools on each cluster in a MetroCluster configuration.

About this task

- You can apply only one scanner policy to a scanner pool.
- If you created a scanner pool for all of the SVMs in a cluster, you must apply a scanner policy on each SVM individually.

Steps

1. Apply a scanner policy:

```
vserver vscan scanner-pool apply-policy -vserver data_SVM -scanner-pool
scanner_pool -scanner-policy primary|secondary|idle -cluster
cluster_to_apply_policy_on
```

A scanner policy can have one of the following values:

- Primary specifies that the scanner pool is active.
- Secondary specifies that the scanner pool is active only if none of the Vscan servers in the primary scanner pool is connected.
- Idle specifies that the scanner pool is inactive.

You must apply all scanner policies from the cluster containing the primary SVM.

The following commands apply scanner policies to the primary and secondary scanner pools on each cluster in a MetroCluster configuration:

```
cluster1::>vserver vscan scanner-pool apply-policy -vserver cifssvm1  
-scanner-pool pool1_for_site1 -scanner-policy primary -cluster  
cluster1

cluster1::>vserver vscan scanner-pool apply-policy -vserver cifssvm1  
-scanner-pool pool2_for_site1 -scanner-policy secondary -cluster  
cluster1

cluster1::>vserver vscan scanner-pool apply-policy -vserver cifssvm1  
-scanner-pool pool1_for_site2 -scanner-policy primary -cluster  
cluster2

cluster1::>vserver vscan scanner-pool apply-policy -vserver cifssvm1  
-scanner-pool pool2_for_site2 -scanner-policy secondary -cluster  
cluster2
```

2. Verify that the scanner pool is active:

```
vserver vscan scanner-pool show -vserver data_SVM|cluster_admin_SVM  
-scanner-pool scanner_pool
```

For a complete list of options, see the man page for the command.

The following command displays the details for the scanner pool pool1:

```
cluster1::> vserver vscan scanner-pool show -vserver cifssvm1  
-scanner-pool pool1_for_site1

Vserver: cifssvm1
Scanner Pool: pool1_for_site1
Applied Policy: primary
Current Status: on
Cluster on Which Policy Is Applied: cluster1
Scanner Pool Config Owner: vserver
List of IPs of Allowed Vscan Servers:
List of Host Names of Allowed Vscan Servers: scan1
List of Privileged Users: cifs\u1,cifs\u2
```

You can use the `vserver vscan scanner-pool show-active` command to view the active scanner pools on an SVM. For complete command syntax, see the man page for the command.

= Commands for managing scanner pools
:icons: font

```
:relative_path: ./antivirus/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

You can modify and delete scanner pools, and manage privileged users and Vscan servers for a scanner pool. You can view summary and details for a scanner pool.

If you want to...	Enter the following command...
Modify a scanner pool	vserver vscan scanner-pool modify
Delete a scanner pool	vserver vscan scanner-pool delete
Add privileged users to a scanner pool	vserver vscan scanner-pool privileged-users add
Delete privileged users from a scanner pool	vserver vscan scanner-pool privileged-users remove
Add Vscan servers to a scanner pool	vserver vscan scanner-pool servers add
Delete Vscan servers from a scanner pool	vserver vscan scanner-pool servers remove
View summary and details for a scanner pool	vserver vscan scanner-pool show
View privileged users for a scanner pool	vserver vscan scanner-pool privileged-users show
View Vscan servers for all scanner pools	vserver vscan scanner-pool servers show

For more information about these commands, see the man pages.

= Configure on-access scanning

= Create an on-access policy

```
:icons: font
```

```
:relative_path: ./antivirus/
```

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

An on-access policy defines the scope of an on-access scan. You can specify the maximum size of the files to be scanned, the extensions of the files to be included in the scan, and the extensions and paths of the files to be excluded from the scan. You can create an on-access policy for an individual SVM or for all the SVMs in a cluster.

About this task

By default, ONTAP creates an on-access policy named “default_CIFS” and enables it for all the SVMs in a

cluster.

You can set the `scan-mandatory` option to off to specify that file access is allowed when no Vscan servers are available for virus scanning. Keep in mind that any file that qualifies for scan exclusion based on the `paths-to-exclude`, `file-ext-to-exclude`, or `max-file-size` parameters is not considered for scanning even if the `scan-mandatory` option is set to on.

For potential issues related to the `scan-mandatory` option, see [Potential connectivity issues involving the scan-mandatory option](#).

By default, only read-write volumes are scanned. You can specify filters that enable scanning of read-only volumes or that restrict scanning to files opened with execute access.

Steps

1. Create an on-access policy:

```
vserver vscan on-access-policy create -vserver data_SVM|cluster_admin_SVM
-policy-name policy_name -protocol CIFS -max-file-size
max_size_of_files_to_scan -filters [scan-ro-volume,][scan-execute-access]
-file-ext-to-include extensions_of_files_to_include -file-ext-to-exclude
extensions_of_files_to_exclude -scan-files-with-no-ext true|false -paths-to
-exclude paths_of_files_to_exclude -scan-mandatory on|off
```

- Specify a data SVM for a policy defined for an individual SVM, a cluster admin SVM for a policy defined for all the SVMs in a cluster.
- The `-file-ext-to-exclude` setting overrides the `-file-ext-to-include` setting.
- Set `-scan-files-with-no-ext` to true to scan files without extensions.

The following command creates an on-access policy named `Policy1` on the `vs1SVM`:

```
cluster1::> vserver vscan on-access-policy create -vserver vs1
-policy-name Policy1 -protocol CIFS -filters scan-ro-volume -max
-file-size 3GB -file-ext-to-include "mp*","tx*" -file-ext-to-exclude
"mp3","txt" -scan-files-with-no-ext false -paths-to-exclude "\vol\ab\",
"\vol\ab\b\"
```

2. Verify that the on-access policy has been created: `vserver vscan on-access-policy show -instance data_SVM|cluster_admin_SVM -policy-name policy_name`

For a complete list of options, see the man page for the command.

The following command displays the details for the `Policy1` policy:

```
cluster1::> vserver vscan on-access-policy show -instance vs1
-priority-name Policy1

          Vserver: vs1
          Policy: Policy1
          Policy Status: off
          Policy Config Owner: vserver
          File-Access Protocol: CIFS
          Filters: scan-ro-volume
          Mandatory Scan: on
          Max File Size Allowed for Scanning: 3GB
          File Paths Not to Scan: \vol\ab\, \vol\ab\
          File Extensions Not to Scan: mp3, txt
          File Extensions to Scan: mp*, tx*
          Scan Files with No Extension: false
```

= Enable an on-access policy

:icons: font

:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

You must enable an on-access policy on an SVM before its files can be scanned. If you created an on-access policy for all the SVMs in a cluster, you must enable the policy on each SVM individually. You can enable only one on-access policy on an SVM at a time.

Steps

1. Enable an on-access policy:

```
vserver vscan on-access-policy enable -vserver data_SVM -policy-name
policy_name
```

The following command enables an on-access policy named `Policy1` on the `vs1` SVM:

```
cluster1::> vserver vscan on-access-policy enable -vserver vs1
-priority-name Policy1
```

2. Verify that the on-access policy is enabled: `vserver vscan on-access-policy show -instance data_SVM -policy-name policy_name`

For a complete list of options, see the man page for the command.

The following command displays the details for the `Policy1` on-access policy:

```
cluster1::> vserver vscan on-access-policy show -instance vs1  
-policy-name Policy1

          Vserver: vs1
          Policy: Policy1
          Policy Status: on
          Policy Config Owner: vserver
          File-Access Protocol: CIFS
          Filters: scan-ro-volume
          Mandatory Scan: on
          Max File Size Allowed for Scanning: 3GB
          File Paths Not to Scan: \vol\ab\, \vol\ab\
          File Extensions Not to Scan: mp3, txt
          File Extensions to Scan: mp*, tx*
          Scan Files with No Extension: false
```

= Modify the Vscan file-operations profile for an SMB share

:icons: font

:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

The Vscan file-operations profile for an SMB share defines which operations on the share can trigger scanning. By default, the parameter is set to standard. You can adjust the parameter as necessary when you create or modify an SMB share.

About this task

For more information on the available values for a Vscan file-operations profile, see “Vscan file-operations profile.”

[Vscan file-operations profile \(on-access scanning only\)](#)

Virus scanning is not performed on a SMB share for which the continuously-available parameter is set to Yes.

Step

1. Modify the value of the Vscan file-operations profile for a SMB share: `vserver cifs share modify -vserver data_SVM -share-name share -path share_path -vscan-fileop-profile no-scan|standard|strict|writes-only`

For a complete list of options, see the man page for the command.

The following command changes the Vscan file operations profile for a SMB share to strict:

```
cluster1::> vserver cifs share modify -vserver vs1 -share-name  
SALES_SHARE -path /sales -vscan-fileop-profile strict
```

= Commands for managing on-access policies

:icons: font

:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can modify, disable, or delete an on-access policy. You can view a summary and details for the policy.

If you want to...	Enter the following command...
Modify an on-access policy	vserver vscan on-access-policy modify
Disable an on-access policy	vserver vscan on-access-policy disable
Delete an on-access policy	vserver vscan on-access-policy delete
View summary and details for an on-access policy	vserver vscan on-access-policy show
Add to the list of paths to exclude	vscan on-access-policy paths-to-exclude add
Delete from the list of paths to exclude	vscan on-access-policy paths-to-exclude remove
View the list of paths to exclude	vscan on-access-policy paths-to-exclude show
Add to the list of file extensions to exclude	vscan on-access-policy file-ext-to-exclude add
Delete from the list of file extensions to exclude	vscan on-access-policy file-ext-to-exclude remove
View the list of file extensions to exclude	vscan on-access-policy file-ext-to-exclude show
Add to the list of file extensions to include	vscan on-access-policy file-ext-to-include add
Delete from the list of file extensions to include	vscan on-access-policy file-ext-to-include remove
View the list of file extensions to include	vscan on-access-policy file-ext-to-include show

For more information about these commands, see the man pages.

= Configure on-demand scanning

= Configure on-demand scanning overview

:icons: font

:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use on-demand scanning to check files for viruses immediately or on a schedule. You might want to run scans only in off-peak hours, for example, or you might want to scan very large files that were excluded from an on-access scan.

You can use a cron schedule to specify when the task runs:

- You can assign a schedule when you create a task.
- You can create a task without assigning a schedule, and use the vserver vscan on-demand-task schedule command to assign a schedule.
- You can use the vserver vscan on-demand-task run command to run a task immediately, whether or not you have assigned a schedule.

Only one task can be scheduled at a time on an SVM.

On-demand scanning does not support scanning of symbolic links or stream files.

= Create an on-demand task

:icons: font

:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

An on-demand task defines the scope of an on-demand scan. You can specify the maximum size of the files to be scanned, the extensions and paths of the files to be included in the scan, and the extensions and paths of the files to be excluded from the scan. Files in subdirectories are scanned by default.

Steps

1. Create an on-demand task:

```
vserver vscan on-demand-task create -vserver data_SVM -task-name task_name
-scan-paths paths_of_files_to_scan -report-directory report_directory_path
-report-expiry-time expiration_time_for_report -schedule cron_schedule -max
-file-size max_size_of_files_to_scan -paths-to-exclude
paths_of_files_to_exclude -file-ext-to-exclude
extensions_of_files_to_exclude -file-ext-to-include
extensions_of_files_to_include -scan-files-with-no-ext true|false
-directory-recursion true|false
```

◦ The `-file-ext-to-exclude` setting overrides the `-file-ext-to-include` setting.

◦ Set `-scan-files-with-no-ext` to true to scan files without extensions.

For a complete list of options, see the man page for the command.

The following command creates an on-access task named Task1 on the vs1SVM:

```
cluster1::> vserver vscan on-demand-task create -vserver vs1 -task  
-name Task1 -scan-paths "/vol1/", "/vol2/cifs/" -report-directory  
"/report" -schedule daily -max-file-size 5GB -paths-to-exclude  
"/vol1/cold-files/" -file-ext-to-include "vmdk?", "mp*" -file-ext-to  
-exclude "mp3", "mp4" -scan-files-with-no-ext false  
[Job 126]: Vscan On-Demand job is queued. Use the "job show -id 126"  
command to view the status.
```

You can use the `job show` command to view the status of the job. You can use the `job pause` and `job resume` commands to pause and restart the job, or the `job stop` command to end the job.

2. Verify that the on-demand task has been created: `vserver vscan on-demand-task show -instance data_SVM -task-name task_name`

For a complete list of options, see the man page for the command.

The following command displays the details for the `Task1` task:

```
cluster1::> vserver vscan on-demand-task show -instance vs1 -task  
-name Task1  
  
          Vserver: vs1  
          Task Name: Task1  
          List of Scan Paths: /vol1/, /vol2/cifs/  
          Report Directory Path: /report  
          Job Schedule: daily  
Max File Size Allowed for Scanning: 5GB  
          File Paths Not to Scan: /vol1/cold-files/  
          File Extensions Not to Scan: mp3, mp4  
          File Extensions to Scan: vmdk?, mp*  
Scan Files with No Extension: false  
          Request Service Timeout: 5m  
          Cross Junction: true  
          Directory Recursion: true  
          Scan Priority: low  
          Report Log Level: info  
Expiration Time for Report: -
```

After you finish

You must enable scanning on the SVM before the task is scheduled to run.

= Schedule an on-demand task
:icons: font
:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

If you have created an on-demand task without assigning a schedule, or if you want to assign a different schedule to a task, you can use the vserver vscan on-demand-task schedule command to assign a schedule to the task.

About this task

The schedule assigned with the vserver vscan on-demand-task schedule command overrides a schedule already assigned with the vserver vscan on-demand-task create command.

Steps

1. Schedule an on-demand task:

```
vserver vscan on-demand-task schedule -vserver data_SVM -task-name  
task_name -schedule cron_schedule
```

The following command schedules an on-access task named Task2 on the vs2SVM:

```
cluster1::> vserver vscan on-demand-task schedule -vserver vs2 -task  
-name Task2 -schedule daily  
[Job 142]: Vscan On-Demand job is queued. Use the "job show -id 142"  
command to view the status.
```

You can use the job show command to view the status of the job. You can use the job pause and job resume commands to pause and restart the job, or the job stop command to end the job.

2. Verify that the on-demand task has been scheduled: vserver vscan on-demand-task show -instance data_SVM -task-name task_name

For a complete list of options, see the man page for the command.

The following command displays the details for the Task 2 task:

```
cluster1::> vserver vscan on-demand-task show -instance vs2 -task  
-name Task2  
  
          Vserver: vs2  
          Task Name: Task2  
          List of Scan Paths: /vol1/, /vol2/cifs/  
          Report Directory Path: /report  
          Job Schedule: daily  
Max File Size Allowed for Scanning: 5GB  
          File Paths Not to Scan: /vol1/cold-files/  
          File Extensions Not to Scan: mp3, mp4  
          File Extensions to Scan: vmdk, mp*  
Scan Files with No Extension: false  
          Request Service Timeout: 5m  
          Cross Junction: true  
          Directory Recursion: true  
          Scan Priority: low  
          Report Log Level: info
```

After you finish

You must enable scanning on the SVM before the task is scheduled to run.

= Run an on-demand task immediately

:icons: font

:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can run an on-demand task immediately, whether or not you have assigned a schedule.

What you'll need

You must have enabled scanning on the SVM.

Step

1. Run an on-demand task immediately:

```
vserver vscan on-demand-task run -vserver data_SVM -task-name task_name
```

The following command runs an on-access task named Task1 on the vs1SVM:

```
cluster1::> vserver vscan on-demand-task run -vserver vs1 -task-name  
Task1  
[Job 161]: Vscan On-Demand job is queued. Use the "job show -id 161"  
command to view the status.
```

You can use the `job show` command to view the status of the job. You can use the `job pause` and `job resume` commands to pause and restart the job, or the `job stop` command to end the job.

= Commands for managing on-demand tasks

:icons: font

:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

You can modify, delete, or unschedule an on-demand task. You can view a summary and details for the task, and manage reports for the task.

If you want to...	Enter the following command...
Modify an on-demand task	<code>vserver vscan on-demand-task modify</code>
Delete an on-demand task	<code>vserver vscan on-demand-task delete</code>
Unschedule an on-demand task	<code>vserver vscan on-demand-task unschedule</code>
View summary and details for an on-demand task	<code>vserver vscan on-demand-task show</code>
View on-demand reports	<code>vserver vscan on-demand-task report show</code>
Delete on-demand reports	<code>vserver vscan on-demand-task report delete</code>

For more information about these commands, see the man pages.

= Enable virus scanning on an SVM

:icons: font

:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

You must enable virus scanning on an SVM before an on-access or on-demand scan can run. The Vscan configuration must exist.

Steps

1. Enable virus scanning on an SVM:

```
vserver vscan enable -vserver data_SVM
```

You can use the `vserver vscan disable` command to disable virus scanning if necessary.

The following command enables virus scanning on the vs1SVM:

```
cluster1::> vserver vscan enable -vserver vs1
```

2. Verify that virus scanning is enabled on the SVM:

```
vserver vscan show -vserver data_SVM
```

For a complete list of options, see the man page for the command.

The following command displays the Vscan status of the vs1SVM:

```
cluster1::> vserver vscan show -vserver vs1  
  
Vserver: vs1  
Vscan Status: on
```

= Reset the status of scanned files

:icons: font
:relative_path: ./antivirus/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Occasionally, you might want to reset the scan status of successfully scanned files on an SVM by using the vserver vscan reset command to discard the cached information for the files. You might want to use this command to restart the virus scanning processing in case of a misconfigured scan, for example.

About this task

After you run the vserver vscan reset command, all eligible files will be scanned the next time they are accessed.

This command can affect performance adversely, depending on the number and size of the files to be rescanned.

Step

1. Reset the status of scanned files:

```
vserver vscan reset -vserver data_SVM
```

The following command resets the status of scanned files on the vs1SVM:

```
cluster1::> vserver vscan reset -vserver vs1
```

= View Vscan event log information

:icons: font

```
:relative_path: ./antivirus/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

You can use the vserver vscan show-events command to view event log information about infected files, updates to Vscan servers, and the like. You can view event information for the cluster or for given nodes, SVMs, or Vscan servers.

What you'll need

Advanced privileges are required for this task.

Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. View Vscan event log information:

```
vserver vscan show-events
```

For a complete list of options, see the man page for the command.

The following command displays event log information for the cluster cluster1:

```
cluster1::*: vserver vscan show-events  
  
Vserver      Node          Server          Event Type      Event  
Time  
-----  
-----  
vs1          Cluster-01    192.168.1.1    file-infected  
9/5/2014 11:37:38  
vs1          Cluster-01    192.168.1.1    scanner-updated  
9/5/2014 11:37:08  
vs1          Cluster-01    192.168.1.1    scanner-connected  
9/5/2014 11:34:55  
3 entries were displayed.
```

= Troubleshoot connectivity issues

= Potential connectivity issues involving the scan-mandatory option

```
:icons: font
```

```
:relative_path: ./antivirus/
```

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

You can use the vserver vscan connection-status show commands to view information about Vscan server connections that you might find helpful in troubleshooting connectivity issues.

By default, the `scan-mandatory` option for on-access scanning denies file access when a Vscan server connection is not available for scanning. Although this option offers important safety features, it can lead to problems in a few situations.

- Before enabling client access, you must ensure that at least one Vscan server is connected to an SVM on each node that has a LIF. If you need to connect servers to SVMs after enabling client access, you must turn off the `scan-mandatory` option on the SVM to ensure that file access is not denied because a Vscan server connection is not available. You can turn the option back on after the server has been connected.
- If a target LIF hosts all the Vscan server connections for an SVM, the connection between the server and the SVM will be lost if the LIF is migrated. To ensure that file access is not denied because a Vscan server connection is not available, you must turn off the `scan-mandatory` option before migrating the LIF. You can turn the option back on after the LIF has been migrated.

Each SVM should have at least two Vscan servers assigned to it. It is a best practice to connect Vscan servers to the storage system over a different network from the one used for client access.

= Commands for viewing Vscan server connection status

:icons: font

:relative_path: ./antivirus/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use the `vserver vscan connection-status show` commands to view summary and detailed information about Vscan server connection status.

h	If you want to...	Enter the following command...
View a summary of Vscan server connections	<code>vserver vscan connection-status show</code>	View details for Vscan server connections
<code>vserver vscan connection-status show-all</code>	View details for connected Vscan servers	<code>vserver vscan connection-status show-connected</code>

For more information about these commands, see the man pages.

= NAS auditing and security tracing

= SMB and NFS auditing and security tracing overview

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use the file access auditing features available for the SMB and NFS protocols with ONTAP, such as native auditing and file policy management using FPolicy.

You should design and implement auditing of SMB and NFS file access events under the following circumstances:

- Basic SMB and NFS protocol file access has been configured.

- You want to create and maintain an auditing configuration using one of the following methods:

- Native ONTAP functionality
- External FPolicy servers

= Audit NAS events on SVMs

= Audit NAS events on SVMs overview

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Auditing for NAS events is a security measure that enables you to track and log certain SMB and NFS events on storage virtual machines (SVMs). This helps you track potential security problems and provides evidence of any security breaches. You can also stage and audit Active Directory central access policies to see what the result of implementing them would be.

== SMB events

You can audit the following events:

- SMB file and folder access events

You can audit SMB file and folder access events on objects stored on FlexVol volumes belonging to the auditing-enabled SVMs.

- SMB logon and logoff events

You can audit SMB logon and logoff events for SMB servers on SVMs.

- Central access policy staging events

You can audit the effective access of objects on SMB servers using permissions applied through proposed central access policies. Auditing through the staging of central access policies enables you to see what the effects are of central access policies before they are deployed.

Auditing of central access policy staging is set up using Active Directory GPOs; however, the SVM auditing configuration must be configured to audit central access policy staging events.

Although you can enable central access policy staging in the auditing configuration without enabling Dynamic Access Control on the SMB server, central access policy staging events are generated only if Dynamic Access Control is enabled. Dynamic Access Control is enabled through a SMB server option. It is not enabled by default.

== NFS events

You can audit file and directory NFSv4 access events on objects stored on SVMs.

= How auditing works

= Basic auditing concepts

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

To understand auditing in ONTAP, you should be aware of some basic auditing concepts.

- **Staging files**

The intermediate binary files on individual nodes where audit records are stored prior to consolidation and conversion. Staging files are contained in staging volumes.

- **Staging volume**

A dedicated volume created by ONTAP to store staging files. There is one staging volume per aggregate. Staging volumes are shared by all audit-enabled storage virtual machines (SVMs) to store audit records of data access for data volumes in that particular aggregate. Each SVM's audit records are stored in a separate directory within the staging volume.

Cluster administrators can view information about staging volumes, but most other volume operations are not permitted. Only ONTAP can create staging volumes. ONTAP automatically assigns a name to staging volumes. All staging volume names begin with MDV_aud_ followed by the UUID of the aggregate containing that staging volume (for example:

MDV_aud_1d0131843d4811e296fc123478563412.)

- **System volumes**

A FlexVol volume that contains special metadata, such as metadata for file services audit logs. The admin SVM owns system volumes, which are visible across the cluster. Staging volumes are a type of system volume.

- **Consolidation task**

A task that gets created when auditing is enabled. This long-running task on each SVM takes the audit records from staging files across the member nodes of the SVM. This task merges the audit records in sorted chronological order, and then converts them to a user-readable event log format specified in the auditing configuration—either the EVT or XML file format. The converted event logs are stored in the audit event log directory that is specified in the SVM auditing configuration.

= How the ONTAP auditing process works

:icons: font

:relative_path: ./has-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./..media/

The ONTAP auditing process is different from the Microsoft auditing process. Before you configure auditing, you should understand how the ONTAP auditing process works.

Audit records are initially stored in binary staging files on individual nodes. If auditing is enabled on an SVM, every member node maintains staging files for that SVM. Periodically, they are consolidated and converted to user-readable event logs, which are stored in the audit event log directory for the SVM.

-- Process when auditing is enabled on an SVM

Auditing can only be enabled on SVMs. When the storage administrator enables auditing on the SVM, the auditing subsystem checks whether staging volumes are present. A staging volume must exist for each

aggregate that contains data volumes owned by the SVM. The auditing subsystem creates any needed staging volumes if they do not exist.

The auditing subsystem also completes other prerequisite tasks before auditing is enabled:

- The auditing subsystem verifies that the log directory path is available and does not contain symlinks.

The log directory must already exist. The auditing subsystem does not assign a default log file location. If the log directory path specified in the auditing configuration is not a valid path, auditing configuration creation fails with the "The specified path "/path" does not exist in the namespace belonging to Vserver "Vserver_name" error.

Configuration creation fails if the directory exists but contains symlinks.

- Auditing schedules the consolidation task.

After this task is scheduled, auditing is enabled. The SVM auditing configuration and the log files persist across a reboot or if the NFS or SMB servers are stopped or restarted.

== Event log consolidation

Log consolidation is a scheduled task that runs on a routine basis until auditing is disabled. When auditing is disabled, the consolidation task verifies that all of the remaining logs are consolidated.

== Guaranteed auditing

By default, auditing is guaranteed. ONTAP guarantees that all auditable file access events (as specified by configured audit policy ACLs) are recorded, even if a node is unavailable. A requested file operation cannot be completed until the audit record for that operation is saved to the staging volume on persistent storage. If audit records cannot be committed to the disk in the staging files, either because of insufficient space or because of other issues, client operations are denied.

An administrator, or account user with privilege level access, can bypass the file audit logging operation by using NetApp Manageability SDK or REST APIs. You can determine if any file actions have been taken using NetApp Manageability SDK or REST APIs by reviewing the command history logs stored in the `audit.log` file.

For more information about command history audit logs, see the "Managing audit logging for management activities" section in [System administration](#).

== Consolidation process when a node is unavailable

If a node containing volumes belonging to an SVM with auditing enabled is unavailable, the behavior of the auditing consolidation task depends on whether the node's storage failover (SFO) partner (or the HA partner in the case of a two-node cluster) is available:

- If the staging volume is available through the SFO partner, the staging volumes last reported from the node are scanned, and consolidation proceeds normally.
- If the SFO partner is not available, the task creates a partial log file.

When a node is not reachable, the consolidation task consolidates the audit records from the other available nodes of that SVM. To identify that it is not complete, the task adds the suffix `.partial` to the consolidated file name.

- After the unavailable node is available, the audit records in that node are consolidated with the audit records from the other nodes at that time.
- All audit records are preserved.

== Event log rotation

Audit event log files are rotated when they reach a configured threshold log size or on a configured schedule. When an event log file is rotated, the scheduled consolidation task first renames the active converted file to a time-stamped archive file, and then creates a new active converted event log file.

== Process when auditing is disabled on the SVM

When auditing is disabled on the SVM, the consolidation task is triggered one final time. All outstanding, recorded audit records are logged in a user-readable format. Existing event logs stored in the event log directory are not deleted when auditing is disabled on the SVM and are available for viewing.

After all existing staging files for that SVM are consolidated, the consolidation task is removed from the schedule. Disabling the auditing configuration for the SVM does not remove the auditing configuration. A storage administrator can reenable auditing at any time.

The auditing consolidation job, which gets created when auditing is enabled, monitors the consolidation task and re-creates it if the consolidation task exits because of an error. Previously, users could delete the auditing consolidation job by using job manager commands such as `job delete`. Users are no longer allowed to delete the auditing consolidation job.

= Auditing requirements and considerations

:icons: font
 :relative_path: ./nas-audit/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Before you configure and enable auditing on your storage virtual machine (SVM), you need to be aware of certain requirements and considerations.

- The maximum number of auditing-enabled SVMs supported in a cluster is 50.
- Auditing is not tied to SMB or NFS licensing.

You can configure and enable auditing even if SMB and NFS licenses are not installed on the cluster.

- NFS auditing supports security ACEs (type U).
- For NFS auditing, there is no mapping between mode bits and auditing ACEs.

When converting ACLs to mode bits, auditing ACEs are skipped. When converting mode bits to ACLs, auditing ACEs are not generated.

- The directory specified in the auditing configuration must exist.

If it does not exist, the command to create the auditing configuration fails.

- The directory specified in the auditing configuration must meet the following requirements:
 - The directory must not contain symbolic links.

If the directory specified in the auditing configuration contains symbolic links, the command to create the auditing configuration fails.

- You must specify the directory by using an absolute path.
You should not specify a relative path, for example, /vs1/.../.
- Auditing is dependent on having available space in the staging volumes.
You must be aware of and have a plan for ensuring that there is sufficient space for the staging volumes in aggregates that contain audited volumes.
- Auditing is dependent on having available space in the volume containing the directory where converted event logs are stored.
You must be aware of and have a plan for ensuring that there is sufficient space in the volumes used to store event logs. You can specify the number of event logs to retain in the auditing directory by using the -rotate-limit parameter when creating an auditing configuration, which can help to ensure that there is enough available space for the event logs in the volume.
- Although you can enable central access policy staging in the auditing configuration without enabling Dynamic Access Control on the SMB server, Dynamic Access Control must be enabled to generate central access policy staging events.

Dynamic Access Control is not enabled by default.

== Aggregate space considerations when enabling auditing

When an auditing configuration is created and auditing is enabled on at least one storage virtual machine (SVM) in the cluster, the auditing subsystem creates staging volumes on all existing aggregates and on all new aggregates that are created. You need to be aware of certain aggregate space considerations when you enable auditing on the cluster.

Staging volume creation might fail due to non-availability of space in an aggregate. This might happen if you create an auditing configuration and existing aggregates do not have enough space to contain the staging volume.

You should ensure that there is enough space on existing aggregates for the staging volumes before enabling auditing on an SVM.

= Limitations for the size of audit records on staging files

:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

The size of an audit record on a staging file cannot be greater than 32 KB.

== When large audit records can occur

Large audit records might occur during management auditing in one of the following scenarios:

- Adding or deleting users to or from groups with a large number of users.
- Adding or deleting a file-share access control list (ACL) on a file-share with a large number of file-share users.
- Other scenarios.

Disable management auditing to avoid this issue. To do this, modify the audit configuration and remove

the following from the list of audit event types:

- file-share
- user-account
- security-group
- authorization-policy-change

After removal, they will not be audited by the file services auditing subsystem.

== The effects of audit records that are too large

- If the size of an audit record is too large (over 32 KB), the audit record is not created and the auditing subsystem generates an event management system (EMS) message similar to the following:

```
File Services Auditing subsystem failed the operation or truncated an audit
record because it was greater than max_audit_record_size value. Vserver
UUID=%s, event_id=%u, size=%u
```

If auditing is guaranteed, the file operation fails because its audit record cannot be created.

- If the size of the audit record is more than 9,999 bytes, the same EMS message as above is displayed. A partial audit record is created with the larger key value missing.
- If the audit record exceeds 2,000 characters, the following error message shows instead of the actual value:

The value of this field was too long to display.

= What the supported audit event log formats are

:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

Supported file formats for the converted audit event logs are **EVTX** and **XML** file formats.

You can specify the type of file format when you create the auditing configuration. By default, ONTAP converts the binary logs to the **EVTX** file format.

= View audit event logs

:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

You can use audit event logs to determine whether you have adequate file security and whether there have been improper file and folder access attempts. You can view and process audit event logs saved in the **EVTX** or **XML** file formats.

- **EVTX** file format

You can open the converted **EVTX** audit event logs as saved files using Microsoft Event Viewer.

There are two options that you can use when viewing event logs using Event Viewer:

- General view
 - Information that is common to all events is displayed for the event record. In this version of ONTAP, the event-specific data for the event record is not displayed. You can use the detailed view to display event-specific data.
 - Detailed view
 - A friendly view and an XML view are available. The friendly view and the XML view display both the information that is common to all events and the event-specific data for the event record.
- XML file format

You can view and process XML audit event logs on third-party applications that support the XML file format. XML viewing tools can be used to view the audit logs provided you have the XML schema and information about definitions for the XML fields. For more information about the XML schema and definitions, see the [ONTAP Auditing Schema Reference](#).

== How active audit logs are viewed using Event Viewer

If the audit consolidation process is running on the cluster, the consolidation process appends new records to the active audit log file for audit-enabled storage virtual machines (SVMs). This active audit log can be accessed and opened over an SMB share in Microsoft Event Viewer.

In addition to viewing existing audit records, Event Viewer has a refresh option that enables you to refresh the content in the console window. Whether the newly appended logs are viewable in Event Viewer depends on whether oplocks are enabled on the share used to access the active audit log.

Oplocks setting on the share	Behavior
Enabled	Event Viewer opens the log that contains events written to it up to that point in time. The refresh operation does not refresh the log with new events appended by the consolidation process.
Disabled	Event Viewer opens the log that contains events written to it up to that point in time. The refresh operation refreshes the log with new events appended by the consolidation process.

This information is applicable only for EVTX event logs. XML event logs can be viewed through SMB in a browser or through NFS using any XML editor or viewer.

= SMB events that can be audited

= SMB events that can be audited overview

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

ONTAP can audit certain SMB events, including certain file and folder access events,

certain logon and logoff events, and central access policy staging events. Knowing which access events can be audited is helpful when interpreting results from the event logs.

The following additional SMB events can be audited in ONTAP 9.2 and later:

Event ID (EVT/EVTX)	Event	Description	Category
4670	Object permissions were changed	OBJECT ACCESS: Permissions changed.	File Access
4907	Object auditing settings were changed	OBJECT ACCESS: Audit settings changed.	File Access
4913	Object Central Access Policy was changed	OBJECT ACCESS: CAP changed.	File Access

The following SMB events can be audited in ONTAP 9.0 and later:

Event ID (EVT/EVTX)	Event	Description	Category
540/4624	An account was successfully logged on	LOGON/LOGOFF: Network (SMB) logon.	Logon and Logoff
529/4625	An account failed to log on	LOGON/LOGOFF: Unknown user name or bad password.	Logon and Logoff
530/4625	An account failed to log on	LOGON/LOGOFF: Account logon time restriction.	Logon and Logoff
531/4625	An account failed to log on	LOGON/LOGOFF: Account currently disabled.	Logon and Logoff
532/4625	An account failed to log on	LOGON/LOGOFF: User account has expired.	Logon and Logoff
533/4625	An account failed to log on	LOGON/LOGOFF: User cannot log on to this computer.	Logon and Logoff
534/4625	An account failed to log on	LOGON/LOGOFF: User not granted logon type here.	Logon and Logoff
535/4625	An account failed to log on	LOGON/LOGOFF: User's password has expired.	Logon and Logoff

537/4625	An account failed to log on	LOGON/LOGOFF: Logon failed for reasons other than above.	Logon and Logoff
539/4625	An account failed to log on	LOGON/LOGOFF: Account locked out.	Logon and Logoff
538/4634	An account was logged off	LOGON/LOGOFF: Local or network user logoff.	Logon and Logoff
560/4656	Open Object/Create Object	OBJECT ACCESS: Object (file or directory) open.	File Access
563/4659	Open Object with the Intent to Delete	OBJECT ACCESS: A handle to an object (file or directory) was requested with the Intent to Delete.	File Access
564/4660	Delete Object	OBJECT ACCESS: Delete Object (file or directory). ONTAP generates this event when a Windows client attempts to delete the object (file or directory).	File Access
567/4663	Read Object/Write Object/Get Object Attributes/Set Object Attributes	<p>OBJECT ACCESS: Object access attempt (read, write, get attribute, set attribute).</p> <p>Note: For this event, ONTAP audits only the first SMB read and first SMB write operation (success or failure) on an object. This prevents ONTAP from creating excessive log entries when a single client opens an object and performs many successive read or write operations to the same object.</p>	File Access
NA/4664	Hard link	OBJECT ACCESS: An attempt was made to create a hard link.	File Access
NA/4818	Proposed central access policy does not grant the same access permissions as the current central access policy	OBJECT ACCESS: Central Access Policy Staging.	File Access

NA/NA Data ONTAP Event ID 9999	Rename Object	OBJECT ACCESS: Object renamed. This is an ONTAP event. It is not currently supported by Windows as a single event.	File Access
NA/NA Data ONTAP Event ID 9998	Unlink Object	OBJECT ACCESS: Object unlinked. This is an ONTAP event. It is not currently supported by Windows as a single event.	File Access

== Additional information about Event 4656

The HandleID tag in the audit XML event contains the handle of the object (file or directory) accessed. The HandleID tag for the EVTX 4656 event contains different information depending on whether the open event is for creating a new object or for opening an existing object:

- If the open event is an open request to create a new object (file or directory), the HandleID tag in the audit XML event shows an empty HandleID (for example: <Data Name="HandleID">0000000000000000;00;0000000;0000000</Data>).

The HandleID is empty because the OPEN (for creating a new object) request gets audited before the actual object creation happens and before a handle exists. Subsequent audited events for the same object have the right object handle in the HandleID tag.

- If the open event is an open request to open an existing object, the audit event will have the assigned handle of that object in the HandleID tag (for example: <Data Name="HandleID">00000000000401;00;00000ea;00123ed4</Data>).

= Determine what the complete path to the audited object is

```
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

The object path printed in the <ObjectName> tag for an audit record contains the name of the volume (in parentheses) and the relative path from the root of the containing volume. If you want to determine the complete path of the audited object, including the junction path, there are certain steps you must take.

Steps

1. Determine what the volume name and relative path to audited object is by looking at the <ObjectName> tag in the audit event.

In this example, the volume name is “data1” and the relative path to the file is /dir1/file.txt:

```
<Data Name="ObjectName"> (data1);/dir1/file.txt</Data>
```

2. Using the volume name determined in the previous step, determine what the junction path is for the volume containing the audited object:

In this example, the volume name is “data1” and the junction path for the volume containing the audited object is /data/data1:

```
volume show -junction -volume data1
```

Vserver	Volume	Language	Active	Junction Path	Junction Path
Source					
vsl	data1	en_US.UTF-8	true	/data/data1	RW_volume

3. Determine the full path to the audited object by appending the relative path found in the <ObjectName> tag to the junction path for the volume.

In this example, the junction path for the volume:

```
/data/data1/dir1/file.txt
```

= Considerations when auditing symlinks and hard links
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

There are certain considerations you must keep in mind when auditing symlinks and hard links.

An audit record contains information about the object being audited including the path to the audited object, which is identified in the ObjectName tag. You should be aware of how paths for symlinks and hard links are recorded in the ObjectName tag.

== Symlinks

A symlink is a file with a separate inode that contains a pointer to the location of a destination object, known as the target. When accessing an object through a symlink, ONTAP automatically interprets the symlink and follows the actual canonical protocol agnostic path to the target object in the volume.

In the following example output, there are two symlinks, both pointing to a file named target.txt. One of the symlinks is a relative symlink and one is an absolute symlink. If either of the symlinks are audited, the ObjectName tag in the audit event contains the path to the file target.txt:

```
[root@host1 audit]# ls -l
total 0
lrwxrwxrwx 1 user1 group1 37 Apr  2 10:09 softlink_fullpath.txt ->
/data/audit/target.txt
lrwxrwxrwx 1 user1 group1 10 Apr  2 09:54 softlink.txt -> target.txt
-rwxrwxrwx 1 user1 group1 16 Apr  2 10:05 target.txt
```

== Hard links

A hard link is a directory entry that associates a name with an existing file on a file system. The hard link points to the inode location of the original file. Similar to how ONTAP interprets symlinks, ONTAP interprets the hard link and follows the actual canonical path to the target object in the volume. When access to a hard link object is audited, the audit event records this absolute canonical path in the `ObjectName` tag rather than the hard link path.

= Considerations when auditing alternate NTFS data streams

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

There are certain considerations you must keep in mind when auditing files with NTFS alternate data streams.

The location of an object being audited is recorded in an event record using two tags, the `ObjectName` tag (the path) and the `HandleID` tag (the handle). To properly identify which stream requests are being logged, you must be aware of what ONTAP records in these fields for NTFS alternate data streams:

- EVTX ID: 4656 events (open and create audit events)
 - The path of the alternate data stream is recorded in the `ObjectName` tag.
 - The handle of the alternate data stream is recorded in the `HandleID` tag.
- EVTX ID: 4663 events (all other audit events, such as read, write, getattr, and so on)
 - The path of the base file, not the alternate data stream, is recorded in the `ObjectName` tag.
 - The handle of the alternate data stream is recorded in the `HandleID` tag.

Example

The following example illustrates how to identify EVTX ID: 4663 events for alternate data streams using the `HandleID` tag. Even though the `ObjectName` tag (path) recorded in the read audit event is to the base file path, the `HandleID` tag can be used to identify the event as an audit record for the alternate data stream.

Stream file names take the form `base_file_name:stream_name`. In this example, the `dir1` directory contains a base file with an alternate data stream having the following paths:

```
/dir1/file1.txt  
/dir1/file1.txt:stream1
```

The output in the following event example is truncated as indicated; the output does not display all of the available output tags for the events.

For an EVTX ID 4656 (open audit event), the audit record output for the alternate data stream records the alternate data stream name in the `ObjectName` tag:

```

- <Event>
- <System>
  <Provider Name="Netapp-Security-Auditing" />
  <EventID>4656</EventID>
  <EventName>Open Object</EventName>
  [...]
  </System>
- <EventData>
  [...]
  **<Data Name="ObjectType">Stream</Data>
  <Data Name="HandleID">00000000000401;00;000001e4;00176767</Data>
  <Data Name="ObjectName">\(data1\);/dir1/file1.txt:stream1</Data>
**
  [...]
</EventData>
</Event>
- <Event>

```

For an EVT ID 4663 (read audit event), the audit record output for the same alternate data stream records the base file name in the `ObjectName` tag; however, the handle in the `HandleID` tag is the alternative data stream's handle and can be used to correlate this event with the alternative data stream:

```

- <Event>
- <System>
  <Provider Name="Netapp-Security-Auditing" />
  <EventID>4663</EventID>
  <EventName>Read Object</EventName>
  [...]
  </System>
- <EventData>
  [...]
  **<Data Name="ObjectType">Stream</Data>
  <Data Name="HandleID">00000000000401;00;000001e4;00176767</Data>
  <Data Name="ObjectName">\(data1\);/dir1/file1.txt</Data> **
  [...]
</EventData>
</Event>
- <Event>

```

= NFS file and directory access events that can be audited

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

ONTAP can audit certain NFS file and directory access events. Knowing what access

events can be audited is helpful when interpreting results from the converted audit event logs.

You can audit the following NFS file and directory access events:

- READ
- OPEN
- CLOSE
- REaddir
- WRITE
- setattr
- CREATE
- LINK
- openattr
- REMOVE
- getattr
- VERIFY
- NVERIFY
- RENAME

To reliably audit NFS RENAME events, you should set audit ACEs on directories instead of files because file permissions are not checked for a RENAME operation if the directory permissions are sufficient.

= Plan the auditing configuration

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Before you configure auditing on storage virtual machines (SVMs), you must understand which configuration options are available and plan the values that you want to set for each option. This information can help you configure the auditing configuration that meets your business needs.

There are certain configuration parameters that are common to all auditing configurations.

Additionally, there are certain parameters that you can use to specify which methods are used when rotating the consolidated and converted audit logs. You can specify one of the three following methods when you configure auditing:

- Rotate logs based on log size

This is the default method used to rotate logs.

- Rotate logs based on a schedule
- Rotate logs based on log size and schedule (whichever event occurs first)

At least one of the methods for log rotation should always be set.

== Parameters common to all auditing configurations

There are two required parameters that you must specify when you create the auditing configuration. There are also three optional parameters that you can specify:

Type of information	Option	Required	Include	Your values
SVM name Name of the SVM on which to create the auditing configuration. The SVM must already exist.	-vserver vserver_name	Yes	Yes	
Log destination path Specifies where the converted audit logs are stored. The path must already exist on the SVM. The path can be up to 864 characters in length and must have read-write permissions. If the path is not valid, the audit configuration command fails. If the SVM is an SVM disaster recovery source, the log destination path cannot be on the root volume. This is because root volume content is not replicated to the disaster recovery destination. You cannot use a FlexCache volume as a log destination (ONTAP 9.7 and later).	-destination text	Yes	Yes	

<p>Categories of events to audit</p> <p>Specifies the categories of events to audit. The following event categories can be audited:</p> <ul style="list-style-type: none"> • File access events (both SMB and NFSv4) • SMB logon and logoff events • Central access policy staging events <p>Central access policy staging events are a new advanced auditing event available beginning with Windows 2012 Active Directory domains. Central access policy staging events log information about changes to central access policies configured in Active Directory.</p> <ul style="list-style-type: none"> • File share category events • Audit policy change events • Local user account management events • Security group management events • Authorization policy change events <p>The default is to audit file access and SMB logon and logoff events.</p> <p>Note: Before you can specify cap-staging as an event category, a SMB server must exist on the SVM. Although you can enable central access policy staging in the auditing configuration without enabling Dynamic Access Control on the SMB server, central access policy staging events are generated only if Dynamic Access Control is enabled. Dynamic Access Control is enabled through a SMB server option. It is not enabled by default.</p>	<pre>-events {file-ops cifs-logon-logoff cap-staging file-share audit-policy-change user-account security-group authorization-policy-change}</pre>	No	
<p>Log file output format</p> <p>Determines the output format of the audit logs. The output format can be either ONTAP-specific XML or Microsoft Windows EVTX log format. By default, the output format is EVTX.</p>	<pre>-format {xml evtx}</pre>	No	

<i>Log files rotation limit</i>	-rotate-limit integer	No	
Determines how many audit log files to retain before rotating the oldest log file out. For example, if you enter a value of 5, the last five log files are retained. A value of 0 indicates that all the log files are retained. The default value is 0.			

== Parameters used for determining when to rotate audit event logs

Rotate logs based on log size

The default is to rotate audit logs based on size.

- The default log size is 100 MB
- If you want to use the default log rotation method and the default log size, you do not need to configure any specific parameters for log rotation.
- If you want to rotate the audit logs based on a log size alone, use the following command to unset the `-rotate-schedule-minute` parameter: `vserver audit modify -vserver vs0 -destination / -rotate-schedule-minute -`

If you do not want to use the default log size, you can configure the `-rotate-size` parameter to specify a custom log size:

Type of information	Option	Required	Include	Your values
<i>Log file size limit</i> Determines the audit log file size limit.	<code>-rotate-size {integer[KB MB GB TB PB]}</code>	No		

Rotate logs based on a schedule

If you choose to rotate the audit logs based on a schedule, you can schedule log rotation by using the time-based rotation parameters in any combination.

- If you use time-based rotation, the `-rotate-schedule-minute` parameter is mandatory.
- All other time-based rotation parameters are optional.
- The rotation schedule is calculated by using all the time-related values.

For example, if you specify only the `-rotate-schedule-minute` parameter, the audit log files are rotated based on the minutes specified on all days of the week, during all hours on all months of the year.

- If you specify only one or two time-based rotation parameters (for example, `-rotate-schedule-month` and `-rotate-schedule-minutes`), the log files are rotated based on the minute values that you specified on all days of the week, during all hours, but only during the specified months.

For example, you can specify that the audit log is to be rotated during the months January, March, and August on all Mondays, Wednesdays, and Saturdays at 10:30 a.m.

- If you specify values for both `-rotate-schedule-dayofweek` and `-rotate-schedule-day`, they are considered independently.

For example, if you specify `-rotate-schedule-dayofweek` as Friday and `-rotate-schedule-day` as 13, then the audit logs would be rotated on every Friday and on the 13th day of the specified month, not just on every Friday the 13th.

- If you want to rotate the audit logs based on a schedule alone, use the following command to unset the `-rotate-size` parameter: `vserver audit modify -vserver vs0 -destination / -rotate-size -`

You can use the following list of available auditing parameters to determine what values to use for configuring a schedule for audit event log rotations:

Type of information	Option	Required	Include	Your values
<p><i>Log rotation schedule: Month</i></p> <p>Determines the monthly schedule for rotating audit logs.</p> <p>Valid values are January through December, and all. For example, you can specify that the audit log is to be rotated during the months January, March, and August.</p>	<code>-rotate-schedule-month</code> <code>chron_month</code>	No		
<p><i>Log rotation schedule: Day of week</i></p> <p>Determines the daily (day of week) schedule for rotating audit logs.</p> <p>Valid values are Sunday through Saturday, and all. For example, you can specify that the audit log is to be rotated on Tuesdays and Fridays, or during all the days of a week.</p>	<code>-rotate-schedule-dayofweek</code> <code>chron_dayofweek</code>	No		
<p><i>Log rotation schedule: Day</i></p> <p>Determines the day of the month schedule for rotating the audit log.</p> <p>Valid values range from 1 through 31. For example, you can specify that the audit log is to be rotated on the 10th and 20th days of a month, or all days of a month.</p>	<code>-rotate-schedule-day</code> <code>chron_dayofmonth</code>	No		

<i>Log rotation schedule: Hour</i> Determines the hourly schedule for rotating the audit log. Valid values range from 0 (midnight) to 23 (11:00 p.m.). Specifying all rotates the audit logs every hour. For example, you can specify that the audit log is to be rotated at 6 (6 a.m.) and 18 (6 p.m.).	-rotate-schedule-hour chron_hour	No	
<i>Log rotation schedule: Minute</i> Determines the minute schedule for rotating the audit log. Valid values range from 0 to 59. For example, you can specify that the audit log is to be rotated at the 30th minute.	-rotate-schedule -minute chron_minute	Yes, if configuring schedule-based log rotation; otherwise, no.	

Rotate logs based on log size and schedule

You can choose to rotate the log files based on log size and a schedule by setting both the `-rotate-size` parameter and the time-based rotation parameters in any combination. For example: if `-rotate-size` is set to 10 MB and `-rotate-schedule-minute` is set to 15, the log files rotate when the log file size reaches 10 MB or on the 15th minute of every hour (whichever event occurs first).

= Create a file and directory auditing configuration on SVMs

= Create the auditing configuration

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Creating a file and directory auditing configuration on your storage virtual machine (SVM) includes understanding the available configuration options, planning the configuration, and then configuring and enabling the configuration. You can then display information about the auditing configuration to confirm that the resultant configuration is the desired configuration.

Before you can begin auditing file and directory events, you must create an auditing configuration on the storage virtual machine (SVM).

Before you begin

If you plan on creating an auditing configuration for central access policy staging, a SMB server must exist on the SVM.

- Although you can enable central access policy staging in the auditing configuration without enabling Dynamic Access Control on the SMB server, central access policy staging events are generated only if Dynamic Access Control is enabled.

 Dynamic Access Control is enabled through a SMB server option. It is not enabled by default.

- If the arguments of a field in a command is invalid, for example, invalid entries for fields, duplicate entries, and non-existent entries, then the command fails before the audit phase.

Such failures do not generate an audit record.

About this task

If the SVM is an SVM disaster recovery source, the destination path cannot be on the root volume.

Step

- Using the information in the planning worksheet, create the auditing configuration to rotate audit logs based on log size or a schedule:

If you want to rotate audit logs by...	Enter...
Log size	<pre>vserver audit create -vserver vserver_name -destination path -events [{file-ops cifs-logon- logoff cap-staging file-share audit-policy- change user-account security-group authorization- policy-change}] [-format {xml evtx}] [-rotate-limit integer] [-rotate-size {integer[KB MB GB TB PB]}]</pre>
A schedule	<pre>vserver audit create -vserver vserver_name -destination path -events [{file-ops cifs-logon- logoff cap-staging}] [-format {xml evtx}] [-rotate- limit integer] [-rotate-schedule-month chron_month] [-rotate-schedule-dayofweek chron_dayofweek] [- rotate-schedule-day chron_dayofmonth] [-rotate- schedule-hour chron_hour] -rotate-schedule-minute chron_minute</pre> <p> The <code>-rotate-schedule-minute</code> parameter is required if you are configuring time-based audit log rotation.</p>

Examples

The following example creates an auditing configuration that audits file operations and SMB logon and logoff events (the default) using size-based rotation. The log format is EVTX (the default). The logs are stored in the `/audit_log` directory. The log file size limit is 200 MB. The logs are rotated when they reach 200 MB in size:

```
cluster1::> vserver audit create -vserver vs1 -destination /audit_log  
-rotate-size 200MB
```

The following example creates an auditing configuration that audits file operations and SMB logon and logoff events (the default) using size-based rotation. The log format is EVTX (the default). The log file size limit is 100 MB (the default), and the log rotation limit is 5:

```
cluster1::> vserver audit create -vserver vs1 -destination /audit_log  
-rotate-limit 5
```

The following example creates an auditing configuration that audits file operations, CIFS logon and logoff events, and central access policy staging events using time-based rotation. The log format is EVTX (the default). The audit logs are rotated monthly, at 12:30 p.m. on all days of the week. The log rotation limit is 5:

```
cluster1::> vserver audit create -vserver vs1 -destination /audit_log  
-events file-ops,cifs-logon-logoff,file-share,audit-policy-change,user-  
account,security-group,authorization-policy-change,cap-staging -rotate  
-schedule-month all -rotate-schedule-dayofweek all -rotate-schedule  
-hour 12 -rotate-schedule-minute 30 -rotate-limit 5
```

= Enable auditing on the SVM

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

After you finish setting up the auditing configuration, you must enable auditing on the storage virtual machine (SVM).

What you'll need

The SVM audit configuration must already exist.

About this task

When an SVM disaster recovery ID discard configuration is first started (after the SnapMirror initialization is complete) and the SVM has an auditing configuration, ONTAP automatically disables the auditing configuration. Auditing is disabled on the read-only SVM to prevent the staging volumes from filling up. You can enable auditing only after the SnapMirror relationship is broken and the SVM is read-write.

Step

1. Enable auditing on the SVM:

```
vserver audit enable -vserver vserver_name  
vserver audit enable -vserver vs1
```

= Verify the auditing configuration

```
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

After completing the auditing configuration, you should verify that auditing is configured properly and is enabled.

Steps

1. Verify the auditing configuration:

```
vserver audit show -instance -vserver vserver_name
```

The following command displays in list form all auditing configuration information for storage virtual machine (SVM) vs1:

```
vserver audit show -instance -vserver vs1
```

```
Vserver: vs1
Auditing state: true
Log Destination Path: /audit_log
Categories of Events to Audit: file-ops
Log Format: evtx
Log File Size Limit: 200MB
Log Rotation Schedule: Month: -
Log Rotation Schedule: Day of Week: -
Log Rotation Schedule: Day: -
Log Rotation Schedule: Hour: -
Log Rotation Schedule: Minute: -
Rotation Schedules: -
Log Files Rotation Limit: 0
```

= Configure file and folder audit policies

= Configure file and folder audit policies

```
:icons: font
```

```
:relative_path: ./nas-audit/
```

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

Implementing auditing on file and folder access events is a two-step process. First, you must create and enable an auditing configuration on storage virtual machines (SVMs). Second, you must configure audit policies on the files and folders that you want to monitor. You can configure audit policies to monitor both successful and failed access attempts.

You can configure both SMB and NFS audit policies. SMB and NFS audit policies have different configuration requirements and audit capabilities.

If the appropriate audit policies are configured, ONTAP monitors SMB and NFS access events as

specified in the audit policies only if the SMB or NFS servers are running.

= Configure audit policies on NTFS security-style files and directories
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Before you can audit file and directory operations, you must configure audit policies on the files and directories for which you want to collect audit information. This is in addition to setting up and enabling the audit configuration. You can configure NTFS audit policies by using the Windows Security tab or by using the ONTAP CLI.

-- Configuring NTFS audit policies using the Windows Security tab
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can configure NTFS audit policies on files and directories by using the **Windows Security** tab in the Windows Properties window. This is the same method used when configuring audit policies on data residing on a Windows client, which enables you to use the same GUI interface that you are accustomed to using.

What you'll need

Auditing must be configured on the storage virtual machine (SVM) that contains the data to which you are applying system access control lists (SACLs).

About this task

Configuring NTFS audit policies is done by adding entries to NTFS SACLs that are associated with an NTFS security descriptor. The security descriptor is then applied to NTFS files and directories. These tasks are automatically handled by the Windows GUI. The security descriptor can contain discretionary access control lists (DACLs) for applying file and folder access permissions, SACLs for file and folder auditing, or both SACLs and DACLs.

To set NTFS audit policies using the Windows Security tab, complete the following steps on a Windows host:

Steps

1. From the **Tools** menu in Windows Explorer, select **Map network drive**.
2. Complete the **Map Network Drive** box:
 - a. Select a **Drive** letter.
 - b. In the **Folder** box, type the SMB server name that contains the share, holding the data you want to audit and the name of the share.

You can specify the IP address of the data interface for the SMB server instead of the SMB server name.

If your SMB server name is “SMB_SERVER” and your share is named “share1”, you should enter \\SMB_SERVER\\share1.

- c. Click **Finish**.

The drive you selected is mounted and ready with the Windows Explorer window displaying files and folders contained within the share.

3. Select the file or directory for which you want to enable auditing access.
4. Right-click the file or directory, and then select **Properties**.
5. Select the **Security** tab.
6. Click **Advanced**.
7. Select the **Auditing** tab.
8. Perform the desired actions:

If you want to....	Do the following
Set up auditing for a new user or group	<ol style="list-style-type: none">a. Click Add.b. In the Enter the object name to select box, type the name of the user or group that you want to add.c. Click OK.
Remove auditing from a user or group	<ol style="list-style-type: none">a. In the Enter the object name to select box, select the user or group that you want to remove.b. Click Remove.c. Click OK.d. Skip the rest of this procedure.
Change auditing for a user or group	<ol style="list-style-type: none">a. In the Enter the object name to select box, select the user or group that you want to change.b. Click Edit.c. Click OK.

If you are setting up auditing on a user or group or changing auditing on an existing user or group, the Auditing Entry for <object> box opens.

9. In the **Apply to** box, select how you want to apply this auditing entry.

You can select one of the following:

- **This folder, subfolders and files**
- **This folder and subfolders**
- **This folder only**
- **This folder and files**
- **Subfolders and files only**
- **Subfolders only**
- **Files only**

If you are setting up auditing on a single file, the **Apply to** box is not active. The **Apply to** box setting defaults to **This object only**.

Because auditing takes SVM resources, select only the minimal level that provides the auditing events that meet your security requirements.

10. In the **Access** box, select what you want audited and whether you want to audit successful events, failure events, or both.

- To audit successful events, select the Success box.
- To audit failure events, select the Failure box.

Select only the actions that you need to monitor to meet your security requirements. For more information about these auditable events, see your Windows documentation. You can audit the following events:

- **Full control**
- **Traverse folder / execute file**
- **List folder / read data**
- **Read attributes**
- **Read extended attributes**
- **Create files / write data**
- **Create folders / append data**
- **Write attributes**
- **Write extended attributes**
- **Delete subfolders and files**
- **Delete**
- **Read permissions**
- **Change permissions**
- **Take ownership**

11. If you do not want the auditing setting to propagate to subsequent files and folders of the original container, select the **Apply these auditing entries to objects and/or containers within this container only** box.

12. Click **Apply**.

13. After you finish adding, removing, or editing auditing entries, click **OK**.

The Auditing Entry for <object> box closes.

14. In the **Auditing** box, select the inheritance settings for this folder.

Select only the minimal level that provides the auditing events that meet your security requirements. You can choose one of the following:

- Select the **Include inheritable auditing entries from this object's parent box**.
- Select the **Replace all existing inheritable auditing entries on all descendants with inheritable auditing entries from this object box**.
- Select both boxes.
- Select neither box.

If you are setting SACLs on a single file, the Replace all existing inheritable auditing entries on all descendants with inheritable auditing entries from this object box is not present in the Auditing box.

15. Click **OK**.

The Auditing box closes.

== Configure NTFS audit policies using the ONTAP CLI

You can configure audit policies on files and folders using the ONTAP CLI. This enables you to configure NTFS audit policies without needing to connect to the data using an SMB share on a Windows client.

You can configure NTFS audit policies by using the `vserver security file-directory` command family.

You can only configure NTFS SACLs using the CLI. Configuring NFSv4 SACLs is not supported with this ONTAP command family. See the man pages for more information about using these commands to configure and add NTFS SACLs to files and folders.

= Configure auditing for UNIX security style files and directories

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

You configure auditing for UNIX security style files and directories by adding audit ACEs to NFSv4.x ACLs. This allows you to monitor certain NFS file and directory access events for security purposes.

About this task

For NFSv4.x, both discretionary and system ACEs are stored in the same ACL. They are not stored in separate DACLs and SACLs. Therefore, you must exercise caution when adding audit ACEs to an existing ACL to avoid overwriting and losing an existing ACL. The order in which you add the audit ACEs to an existing ACL does not matter.

Steps

1. Retrieve the existing ACL for the file or directory by using the `nfs4_getfacl` or equivalent command.

For more information about manipulating ACLs, see the man pages of your NFS client.
2. Append the desired audit ACEs.
3. Apply the updated ACL to the file or directory by using the `nfs4_setfacl` or equivalent command.

= Display information about audit policies applied to files and directories

= Display information about audit policies using the Windows Security tab

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

You can display information about audit policies that have been applied to files and directories by using the Security tab in the Windows Properties window. This is the

same method used for data residing on a Windows server, which enables customers to use the same GUI interface that they are accustomed to using.

About this task

Displaying information about audit policies applied to files and directories enables you to verify that you have the appropriate system access control lists (SACLs) set on specified files and folders.

To display information about SACLs that have been applied to NTFS files and folders, complete the following steps on a Windows host.

Steps

1. From the **Tools** menu in Windows Explorer, select **Map network drive**.
2. Complete the **Map Network Drive** dialog box:
 - a. Select a **Drive** letter.
 - b. In the **Folder** box, type the IP address or SMB server name of the storage virtual machine (SVM) containing the share that holds both the data you would like to audit and the name of the share.
If your SMB server name is “SMB_SERVER” and your share is named “share1”, you should enter \\SMB_SERVER\share1.
 You can specify the IP address of the data interface for the SMB server instead of the SMB server name.
 - c. Click **Finish**.

The drive you selected is mounted and ready with the Windows Explorer window displaying files and folders contained within the share.

3. Select the file or directory for which you display auditing information.
4. Right-click on the file or directory, and select **Properties**.
5. Select the **Security** tab.
6. Click **Advanced**.
7. Select the **Auditing** tab.
8. Click **Continue**.

The Auditing box opens. The **Auditing entries** box displays a summary of users and groups that have SACLs applied to them.

9. In the **Auditing entries** box select the user or group whose SACL entries you want displayed.
10. Click **Edit**.

The Auditing entry for <object> box opens.

11. In the **Access** box, view the current SACLs that are applied to the selected object.
12. Click **Cancel** to close the **Auditing entry for <object>** box.
13. Click **Cancel** to close the **Auditing** box.

= Display information about NTFS audit policies on FlexVol volumes using the CLI
:icons: font

```
:relative_path: ./nas-audit/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

You can display information about NTFS audit policies on FlexVol volumes, including what the security styles and effective security styles are, what permissions are applied, and information about system access control lists. You can use the information to validate your security configuration or to troubleshoot auditing issues.

About this task

Displaying information about audit policies applied to files and directories enables you to verify that you have the appropriate system access control lists (SACLs) set on specified files and folders.

You must provide the name of the storage virtual machine (SVM) and the path to the files or folders whose audit information you want to display. You can display the output in summary form or as a detailed list.

- NTFS security-style volumes and qtrees use only NTFS system access control lists (SACLs) for audit policies.
- Files and folders in a mixed security-style volume with NTFS effective security can have NTFS audit policies applied to them.

Mixed security-style volumes and qtrees can contain some files and directories that use UNIX file permissions, either mode bits or NFSv4 ACLs, and some files and directories that use NTFS file permissions.

- The top level of a mixed security-style volume can have either UNIX or NTFS effective security and might or might not contain NTFS SACLs.
- Because Storage-Level Access Guard security can be configured on a mixed security-style volume or qtree even if the effective security style of the volume root or qtree is UNIX, the output for a volume or qtree path where Storage-Level Access Guard is configured might display both regular file and folder NFSv4 SACLs and Storage-Level Access Guard NTFS SACLs.
- If the path that is entered in the command is to data with NTFS effective security, the output also displays information about Dynamic Access Control ACEs if Dynamic Access Control is configured for the given file or directory path.
- When displaying security information about files and folders with NTFS effective security, UNIX-related output fields contain display-only UNIX file permission information.

NTFS security-style files and folders use only NTFS file permissions and Windows users and groups when determining file access rights.

- ACL output is displayed only for files and folders with NTFS or NFSv4 security.

This field is empty for files and folders using UNIX security that have only mode bit permissions applied (no NFSv4 ACLs).

- The owner and group output fields in the ACL output apply only in the case of NTFS security descriptors.

Step

1. Display file and directory audit policy settings with the desired level of detail:

If you want to display information...	Enter the following command...
In summary form	vserver security file-directory show -vserver vserver_name -path path
As a detailed list	vserver security file-directory show -vserver vserver_name -path path -expand-mask true

Examples

The following example displays the audit policy information for the path `/corp` in SVM vs1. The path has NTFS effective security. The NTFS security descriptor contains both a SUCCESS and a SUCCESS/FAIL SACL entry.

```
cluster::> vserver security file-directory show -vserver vs1 -path /corp
          Vserver: vs1
          File Path: /corp
          File Inode Number: 357
          Security Style: ntfs
          Effective Style: ntfs
          DOS Attributes: 10
          DOS Attributes in Text: ----D---
          Expanded Dos Attributes: -
          Unix User Id: 0
          Unix Group Id: 0
          Unix Mode Bits: 777
          Unix Mode Bits in Text: rwxrwxrwx
          ACLs: NTFS Security Descriptor
          Control:0x8014
          Owner:DOMAIN\Administrator
          Group:BUILTIN\Administrators
          SACL - ACEs
          ALL-DOMAIN\Administrator-0x100081-
OI|CI|SA|FA
          SUCCESSFUL-DOMAIN\user1-0x100116-OI|CI|SA
          DACL - ACEs
          ALLOW-BUILTIN\Administrators-0x1f01ff-OI|CI
          ALLOW-BUILTIN\Users-0x1f01ff-OI|CI
          ALLOW-CREATOR OWNER-0x1f01ff-OI|CI
          ALLOW-NT AUTHORITY\SYSTEM-0x1f01ff-OI|CI
```

The following example displays the audit policy information for the path `/datavol1` in SVM vs1. The path contains both regular file and folder SACLs and Storage-Level Access Guard SACLs.

```

cluster::> vserver security file-directory show -vserver vs1 -path
/datavoll

          Vserver: vs1
          File Path: /datavoll
          File Inode Number: 77
          Security Style: ntfs
          Effective Style: ntfs
          DOS Attributes: 10
          DOS Attributes in Text: ----D---
          Expanded Dos Attributes: -

= Ways to display information about file security and audit policies

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use the wildcard character (*) to display information about file security and audit policies of all files and directories under a given path or a root volume.

The wildcard character (*) can be used as the last subcomponent of a given directory path below which you want to display information of all files and directories.

If you want to display information of a particular file or directory named as "/*", then you need to provide the complete path inside double quotes ("").

Example

The following command with the wildcard character displays the information about all files and directories below the path /1/ of SVM vs1:

```

cluster::> vserver security file-directory show -vserver vs1 -path /1/*
                                         Vserver: vs1
                                         File Path: /1/1
                                         Security Style: mixed
                                         Effective Style: ntfs
                                         DOS Attributes: 10
                                         DOS Attributes in Text: ----D---
                                         Expanded Dos Attributes: -
                                             Unix User Id: 0
                                             Unix Group Id: 0

= CLI change events that can be audited

= CLI change events that can be audited overview

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

ONTAP can audit certain CLI change events, including certain SMB-share events, certain audit policy events, certain local security group events, local user group events, and authorization policy events. Understanding which change events can be audited is helpful when interpreting results from the event logs.

You can manage storage virtual machine (SVM) auditing CLI change events by manually rotating the audit logs, enabling or disabling auditing, displaying information about auditing change events, modifying auditing change events, and deleting auditing change events.

As an administrator, if you execute any command to change configuration related to the SMB-share, local user-group, local security-group, authorization-policy, and audit-policy events, a record generates and the corresponding event gets audited:

Auditing Category	Events	Event IDs	Run this command...
-------------------	--------	-----------	---------------------

Mhost Auditing	policy-change	[4719] Audit configuration changed	vserver audit disable enable modify
	file-share	[5142] Network share was added	vserver cifs share create
		[5143] Network share was modified	vserver cifs share modify vserver cifs share create modify delete vserver cifs share add remove
		[5144] Network share deleted	vserver cifs share delete

Auditing

	Rename	users-and-groups local-user rename
security-group	[4731] Local Security Group created	vserver cifs users-and-groups local-group create vserver services name-service unix-group create
	[4734] Local Security Group deleted	vserver cifs users-and-groups local-group delete vserver services name-service unix-group delete
	[4735] Local Security Group Modified	vserver cifs users-and-groups local-group rename modify vserver services name-service unix-group modify
	[4732] User added to Local Group	vserver cifs users-and-groups local-group add-members vserver services name-service unix-group adduser
	[4733] User Removed from Local Group	vserver cifs users-and-groups local-group remove-members vserver services name-service unix-group deluser
	[4704] User Rights Assigned	vserver cifs users-and-groups privilege add-privilege
authorization-policy-change	[4705] User Rights Removed	vserver cifs users-and-groups privilege remove-privilege reset-privilege

```
= Manage file-share event
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/
```

When a file-share event is configured for a storage virtual machine (SVM) and an audit is enabled, audit events are generated. The file-share events are generated when the SMB network share is modified using `vserver cifs share` related commands.

The file-share events with the event-ids 5142, 5143, and 5144 are generated when a SMB network share is added, modified, or deleted for the SVM. The SMB network share configuration is modified using the `cifs share access control create|modify|delete` commands.

The following example displays a file-share event with the ID 5143 is generated, when a share object called '`audit_dest`' is created:

```
netapp-clus1::*: cifs share create -share-name audit_dest -path
/audit_dest
- System
  - Provider
    [ Name] NetApp-Security-Auditing
    [ Guid] {3CB2A168-FE19-4A4E-BDAD-DCF422F13473}
EventID 5142
EventName Share Object Added
...
...
ShareName audit_dest
SharePath /audit_dest
ShareProperties olocks;browsable;changenotify;show-previous-
versions;
SD O:BAG:S-1-5-21-2447422786-1297661003-4197201688-513D:(A;;FA;;;WD)
```

```
= Manage audit-policy-change event
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/
```

When an audit-policy-change event is configured for a storage virtual machine (SVM) and an audit is enabled, audit events are generated. The audit-policy-change events are generated when an audit policy is modified using `vserver audit` related commands.

The audit-policy-change event with the event-id 4719 is generated whenever an audit policy is disabled, enabled, or modified and helps to identify when a user attempts to disable auditing to cover the tracks. It is configured by default and requires diagnostic privilege to disable.

The following example displays an audit-policy change event with the ID 4719 generated, when an audit

is disabled:

```
netapp-clus1::>*> vserver audit disable -vserver vserver_1
- System
  - Provider
    [ Name] NetApp-Security-Auditing
    [ Guid] {3CB2A168-FE19-4A4E-BDAD-DCF422F13473}
    EventID 4719
    EventName Audit Disabled
    ...
    ...
    SubjectUserName admin
    SubjectUserSid 65533-1001
    SubjectDomainName ~
    SubjectIP console
    SubjectPort
```

= Manage user-account event

:icons: font

:relative_path: ./has-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

When a user-account event is configured for a storage virtual machine (SVM) and an audit is enabled, audit events are generated.

The user-account events with event-ids 4720, 4722, 4724, 4725, 4726, 4738, and 4781 are generated when a local SMB or NFS user is created or deleted from the system, local user account is enabled, disabled or modified, and local SMB user password is reset or changed. The user-account events are generated when a user account is modified using `vserver cifs users-and-groups <local user>` and `vserver services name-service <unix user>` commands.

The following example displays a user account event with the ID 4720 generated, when a local SMB user is created:

```
netapp-clus1::*> vserver cifs users-and-groups local-user create -user  
-name testuser -is-account-disabled false -vserver vserver_1  
Enter the password:  
Confirm the password:  
  
- System  
- Provider  
[ Name] NetApp-Security-Auditing  
[ Guid] {3CB2A168-FE19-4A4E-BDAD-DCF422F13473}  
EventID 4720  
EventName Local Cifs User Created  
...  
...  
TargetUserName testuser  
TargetDomainName NETAPP-CLUS1  
TargetSid S-1-5-21-2447422786-1297661003-4197201688-1003  
TargetType CIFS  
DisplayName testuser  
PasswordLastSet 1472662216  
AccountExpires NO  
PrimaryGroupId 513  
UserAccountControl %%0200  
SidHistory ~  
PrivilegeList ~
```

The following example displays a user account event with the ID 4781 generated, when the local SMB user created in the preceding example is renamed:

```
netapp-clus1::>*> vserver cifs users-and-groups local-user rename -user  
-name testuser -new-user-name testuser1  
- System  
- Provider  
[ Name] NetApp-Security-Auditing  
[ Guid] {3CB2A168-FE19-4A4E-BDAD-DCF422F13473}  
EventID 4781  
EventName Local Cifs User Renamed  
...  
...  
OldTargetUserName testuser  
NewTargetUserName testuser1  
TargetDomainName NETAPP-CLUS1  
TargetSid S-1-5-21-2447422786-1297661003-4197201688-1000  
TargetType CIFS  
SidHistory ~  
PrivilegeList ~
```

= Manage security-group event

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

When a security-group event is configured for a storage virtual machine (SVM) and an audit is enabled, audit events are generated.

The security-group events with event-ids 4731, 4732, 4733, 4734, and 4735 are generated when a local SMB or NFS group is created or deleted from the system, and local user is added or removed from the group. The security-group-events are generated when a user account is modified using `vserver cifs users-and-groups <local-group>` and `vserver services name-service <unix-group>` commands.

The following example displays a security group event with the ID 4731 generated, when a local UNIX security group is created:

```
netapp-clus1::>* vserver services name-service unix-group create -name testunixgroup -id 20
- System
- Provider
[ Name] NetApp-Security-Auditing
[ Guid] {3CB2A168-FE19-4A4E-BDAD-DCF422F13473}
EventID 4731
EventName Local Unix Security Group Created
...
...
SubjectUserName admin
SubjectUserSid 65533-1001
SubjectDomainName ~
SubjectIP console
SubjectPort
TargetUserName testunixgroup
TargetDomainName
TargetGid 20
TargetType NFS
PrivilegeList ~
GidHistory ~
```

= Manage authorization-policy-change event

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

When authorization-policy-change event is configured for a storage virtual machine (SVM) and an audit is enabled, audit events are generated.

The authorization-policy-change events with the event-ids 4704 and 4705 are generated whenever the authorization rights are granted or revoked for an SMB user and SMB group. The authorization-policy-change events are generated when the authorization rights are assigned or revoked using `vserver cifs users-and-groups privilege` related commands.

The following example displays an authorization policy event with the ID 4704 generated, when the authorization rights for a SMB user group are assigned:

```
netapp-clus1::> vserver cifs users-and-groups privilege add-privilege  
-user-or-group-name testcifslocalgroup -privileges *  
- System  
- Provider  
[ Name] NetApp-Security-Auditing  
[ Guid] {3CB2A168-FE19-4A4E-BDAD-DCF422F13473}  
EventID 4704  
EventName User Right Assigned  
...  
...  
TargetUserOrGroupName testcifslocalgroup  
TargetUserOrGroupDomainName NETAPP-CLUS1  
TargetUserOrGroupSid S-1-5-21-2447422786-1297661003-4197201688-1004;  
PrivilegeList  
SeTcbPrivilege;SeBackupPrivilege;SeRestorePrivilege;SeTakeOwnershipPriv  
ilege;SeSecurityPrivilege;SeChangeNotifyPrivilege;  
TargetType CIFS
```

= Manage auditing configurations

= Manually rotate the audit event logs

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Before you can view the audit event logs, the logs must be converted to user-readable formats. If you want to view the event logs for a specific storage virtual machine (SVM) before ONTAP automatically rotates the log, you can manually rotate the audit event logs on an SVM.

Step

1. Rotate the audit event logs by using the `vserver audit rotate-log` command.

```
vserver audit rotate-log -vserver vs1
```

The audit event log is saved in the SVM audit event log directory with the format specified by the auditing configuration (XML or EVT), and can be viewed by using the appropriate application.

= Enable and disable auditing on SVMs

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can enable or disable auditing on storage virtual machines (SVMs). You might want to temporarily stop file and directory auditing by disabling auditing. You can enable auditing at any time (if an auditing configuration exists).

What you'll need

Before you can enable auditing on the SVM, the SVM's auditing configuration must already exist.

About this task

Disabling auditing does not delete the auditing configuration.

Steps

1. Perform the appropriate command:

If you want auditing to be...	Enter the command...
Enabled	vserver audit enable -vserver vserver_name
Disabled	vserver audit disable -vserver vserver_name

2. Verify that auditing is in the desired state:

```
vserver audit show -vserver vserver_name
```

Examples

The following example enables auditing for SVM vs1:

```
cluster1::> vserver audit enable -vserver vs1

cluster1::> vserver audit show -vserver vs1

          Vserver: vs1
          Auditing state: true
          Log Destination Path: /audit_log
          Categories of Events to Audit: file-ops, cifs-logon-logoff
          Log Format: evtx
          Log File Size Limit: 100MB
          Log Rotation Schedule: Month: -
          Log Rotation Schedule: Day of Week: -
          Log Rotation Schedule: Day: -
          Log Rotation Schedule: Hour: -
          Log Rotation Schedule: Minute: -
          Rotation Schedules: -
          Log Files Rotation Limit: 10
```

The following example disables auditing for SVM vs1:

```
cluster1::> vserver audit disable -vserver vs1

          Vserver: vs1
          Auditing state: false
          Log Destination Path: /audit_log
          Categories of Events to Audit: file-ops, cifs-logon-logoff
          Log Format: evtx
          Log File Size Limit: 100MB
          Log Rotation Schedule: Month: -
          Log Rotation Schedule: Day of Week: -
          Log Rotation Schedule: Day: -
          Log Rotation Schedule: Hour: -
          Log Rotation Schedule: Minute: -
          Rotation Schedules: -
          Log Files Rotation Limit: 10
```

= Display information about auditing configurations

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can display information about auditing configurations. The information can help you determine whether the configuration is what you want in place for each SVM. The displayed information also enables you to verify whether an auditing configuration is enabled.

About this task

You can display detailed information about auditing configurations on all SVMs or you can customize what information is displayed in the output by specifying optional parameters. If you do not specify any of the optional parameters, the following is displayed:

- SVM name to which the auditing configuration applies
- The audit state, which can be `true` or `false`

If the audit state is `true`, auditing is enabled. If the audit state is `false`, auditing is disabled.

- The categories of events to audit
- The audit log format
- The target directory where the auditing subsystem stores consolidated and converted audit logs

Step

1. Display information about the auditing configuration by using the `vserver audit show` command.

For more information about using the command, see the man pages.

Examples

The following example displays a summary of the auditing configuration for all SVMs:

```
cluster1::> vserver audit show

Vserver      State   Event Types Log Format Target Directory
----- -----
vs1          false   file-ops    evtx      /audit_log
```

The following example displays, in list form, all auditing configuration information for all SVMs:

```
cluster1::> vserver audit show -instance

          Vserver: vs1
          Auditing state: true
          Log Destination Path: /audit_log
          Categories of Events to Audit: file-ops
          Log Format: evtx
          Log File Size Limit: 100MB
          Log Rotation Schedule: Month: -
          Log Rotation Schedule: Day of Week: -
          Log Rotation Schedule: Day: -
          Log Rotation Schedule: Hour: -
          Log Rotation Schedule: Minute: -
          Rotation Schedules: -
          Log Files Rotation Limit: 0
```

= Commands for modifying auditing configurations

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

If you want to change an auditing setting, you can modify the current configuration at any time, including modifying the log path destination and log format, modifying the categories of events to audit, how to automatically save log files, and specify the maximum number of log files to save.

If you want to...	Use this command...
Modify the log destination path	vserver audit modify with the -destination parameter

Modify the category of events to audit	vserver audit modify with the -events parameter
	 To audit central access policy staging events, the Dynamic Access Control (DAC) SMB server option must be enabled on the storage virtual machine (SVM).
Modify the log format	vserver audit modify with the -format parameter
Enabling automatic saves based on internal log file size	vserver audit modify with the -rotate-size parameter
Enabling automatic saves based on a time interval	vserver audit modify with the -rotate-schedule-month , -rotate-schedule-dayofweek , -rotate-schedule-day , -rotate-schedule-hour , and -rotate-schedule-minute parameters
Specifying the maximum number of saved log files	vserver audit modify with the -rotate-limit parameter

= Delete an auditing configuration

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

In you no longer want to audit file and directory events on the storage virtual machine (SVM) and do not want to maintain an auditing configuration on the SVM, you can delete the auditing configuration.

Steps

1. Disable the auditing configuration:

```
vserver audit disable -vserver vserver_name
```

```
vserver audit disable -vserver vs1
```

2. Delete the auditing configuration:

```
vserver audit delete -vserver vserver_name
```

```
vserver audit delete -vserver vs1
```

= What the process is when reverting

:icons: font

```
:relative_path: ./nas-audit/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

If you plan to revert the cluster, you should be aware of the revert process ONTAP follows when there are auditing-enabled storage virtual machines (SVMs) in the cluster. You must take certain actions before reverting.

== Reverting to a version of ONTAP that does not support the auditing of SMB logon and logoff events and central access policy staging events

Support for auditing of SMB logon and logoff events and for central access policy staging events starts with clustered Data ONTAP 8.3. If you are reverting to a version of ONTAP that does not support these event types and you have auditing configurations that monitor these event types, you must change the auditing configuration for those audit-enabled SVMs before reverting. You must modify the configuration so that only file-op events are audited.

= Troubleshoot auditing and staging volume space issues

:icons: font

```
:relative_path: ./nas-audit/
```

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

Issues can arise when there is insufficient space on either the staging volumes or on the volume containing the audit event logs. If there is insufficient space, new audit records cannot be created, which prevents clients from accessing data, and access requests fail. You should know how to troubleshoot and resolve these volume space issues.

== Troubleshoot space issues related to the event log volumes

If volumes containing event log files run out of space, auditing cannot convert log records into log files. This results in client access failures. You must know how to troubleshoot space issues related to event log volumes.

- storage virtual machine (SVM) and cluster administrators can determine whether there is insufficient volume space by displaying information about volume and aggregate usage and configuration.
- If there is insufficient space in the volumes containing event logs, SVM and cluster administrators can resolve the space issues by either removing some of the event log files or by increasing the size of the volume.

If the aggregate that contains the event log volume is full, then the size of the aggregate must be increased before you can increase the size of the volume. Only a cluster administrator can increase the size of an aggregate.

- The destination path for the event log files can be changed to a directory on another volume by modifying the auditing configuration.

Data access is denied in the following cases:

- If the destination directory is deleted.
- If the file limit on a volume, which hosts the destination directory, reaches to its maximum level.

For more information about how to view information about volumes and increasing volume size, see the [Logical storage management](#)

For more information about how to view information about aggregates and managing aggregates, see [Disks and aggregates management](#).

== Troubleshoot space issues related to the staging volumes

If any of the volumes containing staging files for your storage virtual machine (SVM) runs out of space, auditing cannot write log records into staging files. This results in client access failures. To troubleshoot this issue, you need to determine whether any of the staging volumes used in the SVM are full by displaying information about volume usage.

If the volume containing the consolidated event log files has sufficient space but there are still client access failures due to insufficient space, then the staging volumes might be out of space. The SVM administrator must contact you to determine whether the staging volumes that contain staging files for the SVM have insufficient space. The auditing subsystem generates an EMS event if auditing events cannot be generated due to insufficient space in a staging volume. The following message is displayed: No space left on device. Only you can view information about staging volumes; SVM administrators cannot.

All staging volume names begin with `MDV_aud_` followed by the UUID of the aggregate containing that staging volume. The following example shows four system volumes on the admin SVM, which were automatically created when a file services auditing configuration was created for a data SVM in the cluster:

```
cluster1::> volume show -vserver cluster1
Vserver    Volume        Aggregate     State      Type       Size
Available   Used%
-----  -----
cluster1  MDV_aud_1d0131843d4811e296fc123478563412
                  aggr0          online      RW         2GB
1.90GB      5%
cluster1  MDV_aud_8be27f813d7311e296fc123478563412
                  root_vs0        online      RW         2GB
1.90GB      5%
cluster1  MDV_aud_9dc4ad503d7311e296fc123478563412
                  aggr1          online      RW         2GB
1.90GB      5%
cluster1  MDV_aud_a4b887ac3d7311e296fc123478563412
                  aggr2          online      RW         2GB
1.90GB      5%
4 entries were displayed.
```

If there is insufficient space in the staging volumes, you can resolve the space issues by increasing the size of the volume.

If the aggregate that contains the staging volume is full, then the size of the aggregate must be increased before you can increase the size of the volume. Only you can increase the size of an aggregate; SVM administrators cannot.

If one or more aggregates have an available space of less than 2 GB, the SVM audit creation fails. When the SVM audit creation fails, the staging volumes that were created are deleted.

= Use FPolicy for file monitoring and management on SVMs

= How FPolicy works

= What the two parts of the FPolicy solution are

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

FPolicy is a file access notification framework that is used to monitor and manage file access events on storage virtual machines (SVMs).

There are two parts to an FPolicy solution. The ONTAP FPolicy framework manages activities on the cluster and sends notifications to external FPolicy servers. External FPolicy servers process notifications sent by ONTAP FPolicy.

The ONTAP framework creates and maintains the FPolicy configuration, monitors file events, and sends notifications to external FPolicy servers. ONTAP FPolicy provides the infrastructure that allows communication between external FPolicy servers and storage virtual machine (SVM) nodes.

The FPolicy framework connects to external FPolicy servers and sends notifications for certain file system events to the FPolicy servers when these events occur as a result of client access. The external FPolicy servers process the notifications and send responses back to the node. What happens as a result of the notification processing depends on the application and whether the communication between the node and the external servers is asynchronous or synchronous.

= What synchronous and asynchronous notifications are

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

FPolicy sends notifications to external FPolicy servers via the FPolicy interface. The notifications are sent either in synchronous or asynchronous mode. The notification mode determines what ONTAP does after sending notifications to FPolicy servers.

- **Asynchronous notifications**

With asynchronous notifications, the node does not wait for a response from the FPolicy server, which enhances overall throughput of the system. This type of notification is suitable for applications where the FPolicy server does not require that any action be taken as a result of notification evaluation. For example, asynchronous notifications are used when the storage virtual machine (SVM) administrator

wants to monitor and audit file access activity.

If an FPolicy server operating in asynchronous mode experiences a network outage, FPolicy notifications generated during the outage are stored on the storage node. When the FPolicy server comes back online, it is alerted of the stored notifications and can fetch them from the storage node. The length of time the notifications can be stored during an outage is configurable up to 10 minutes.

- **Synchronous notifications**

When configured to run in synchronous mode, the FPolicy server must acknowledge every notification before the client operation is allowed to continue. This type of notification is used when an action is required based on the results of notification evaluation. For example, synchronous notifications are used when the SVM administrator wants to either allow or deny requests based on criteria specified on the external FPolicy server.

== Synchronous and asynchronous applications

There are many possible uses for FPolicy applications, both asynchronous and synchronous.

Asynchronous applications are ones where the external FPolicy server does not alter access to files or directories or modify data on the storage virtual machine (SVM). For example:

- File access and audit logging
- Storage resource management

Synchronous applications are ones where data access is altered or data is modified by the external FPolicy server. For example:

- Quota management
- File access blocking
- File archiving and hierarchical storage management
- Encryption and decryption services
- Compression and decompression services

You can use the SDK for FPolicy to identify and implement other applications as well.

= Roles that cluster components play with FPolicy implementation

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

The cluster, the contained storage virtual machines (SVMs), and data LIFs all play a role in an FPolicy implementation.

- **cluster**

The cluster contains the FPolicy management framework and maintains and manages information about all FPolicy configurations in the cluster.

- **SVM**

An FPolicy configuration is defined at the SVM level. The scope of the configuration is the SVM, and it

only operates on SVM resources. One SVM configuration cannot monitor and send notifications for file access requests that are made for data residing on another SVM.

FPolicy configurations can be defined on the admin SVM. After configurations are defined on the admin SVM, they can be seen and used in all SVMs.

- **data LIFs**

Connections to the FPolicy servers are made through data LIFs belonging to the SVM with the FPolicy configuration. The data LIFs used for these connections can fail over in the same manner as data LIFs used for normal client access.

= How FPolicy works with external FPolicy servers

= How FPolicy works with external FPolicy servers overview

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

After FPolicy is configured and enabled on the storage virtual machine (SVM), FPolicy runs on every node on which the SVM participates. FPolicy is responsible for establishing and maintaining connections with external FPolicy servers (FPolicy servers), for notification processing, and for managing notification messages to and from FPolicy servers.

Additionally, as part of connection management, FPolicy has the following responsibilities:

- Ensures that file notification flows through the correct LIF to the FPolicy server.
- Ensures that when multiple FPolicy servers are associated with a policy, load balancing is done when sending notifications to the FPolicy servers.
- Attempts to reestablish the connection when a connection to an FPolicy server is broken.
- Sends the notifications to FPolicy servers over an authenticated session.
- Manages the passthrough-read data connection established by the FPolicy server for servicing client requests when passthrough-read is enabled.

= How control channels are used for FPolicy communication

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

FPolicy initiates a control channel connection to an external FPolicy server from the data LIFs of each node participating on a storage virtual machine (SVM). FPolicy uses control channels for transmitting file notifications; therefore, an FPolicy server might see multiple control channel connections based on SVM topology.

= How privileged data access channels are used for synchronous communication

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

With synchronous use cases, the FPolicy server accesses data residing on the storage virtual machine (SVM) through a privileged data access path. Access through the privileged path exposes the complete file system to the FPolicy server. It can access data files to collect information, to scan files, read files, or write into files.

Because the external FPolicy server can access the entire file system from the root of the SVM through the privileged data channel, the privileged data channel connection must be secure.

= How FPolicy connection credentials are used with privileged data access channels
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

The FPolicy server makes privileged data access connections to cluster nodes by using a specific Windows user credential that is saved with the FPolicy configuration. SMB is the only supported protocol for making a privileged data access channel connection.

If the FPolicy server requires privileged data access, the following conditions must be met:

- A SMB license must be enabled on the cluster.
- The FPolicy server must run under the credentials configured in the FPolicy configuration.

When making a data channel connection, FPolicy uses the credential for the specified Windows user name. Data access is made over the admin share ONTAP_ADMIN\$.

= What granting super user credentials for privileged data access means
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

ONTAP uses the combination of the IP address and the user credential configured in the FPolicy configuration to grant super user credentials to the FPolicy server.

Super user status grants the following privileges when the FPolicy server accesses data:

- Avoid permission checks
 - The user avoids checks on files and directory access.
- Special locking privileges

ONTAP allows read, write, or modify access to any file regardless of existing locks. If the FPolicy server takes byte range locks on the file, it results in immediate removal of existing locks on the file.

- Bypass any FPolicy checks
 - Access does not generate any FPolicy notifications.

= How FPolicy manages policy processing
:icons: font
:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

There might be multiple FPolicy policies assigned to your storage virtual machine (SVM); each with a different priority. To create an appropriate FPolicy configuration on the SVM, it is important to understand how FPolicy manages policy processing.

Each file access request is initially evaluated to determine which policies are monitoring this event. If it is a monitored event, information about the monitored event along with interested policies is passed to FPolicy where it is evaluated. Each policy is evaluated in order of the assigned priority.

You should consider the following recommendations when configuring policies:

- When you want a policy to always be evaluated before other policies, configure that policy with a higher priority.
- If the success of requested file access operation on a monitored event is a prerequisite for a file request that is evaluated against another policy, give the policy that controls the success or failure of the first file operation a higher priority.

For example, if one policy manages FPolicy file archiving and restore functionality and a second policy manages file access operations on the online file, the policy that manages file restoration must have a higher priority so that the file is restored before the operation managed by the second policy can be allowed.

- If you want all policies that might apply to a file access operation to be evaluated, give synchronous policies a lower priority.

You can reorder policy priorities for existing policies by modifying the policy sequence number. However, to have FPolicy evaluate policies based on the modified priority order, you must disable and reenable the policy with the modified sequence number.

= What the node-to-external FPolicy server communication process is

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

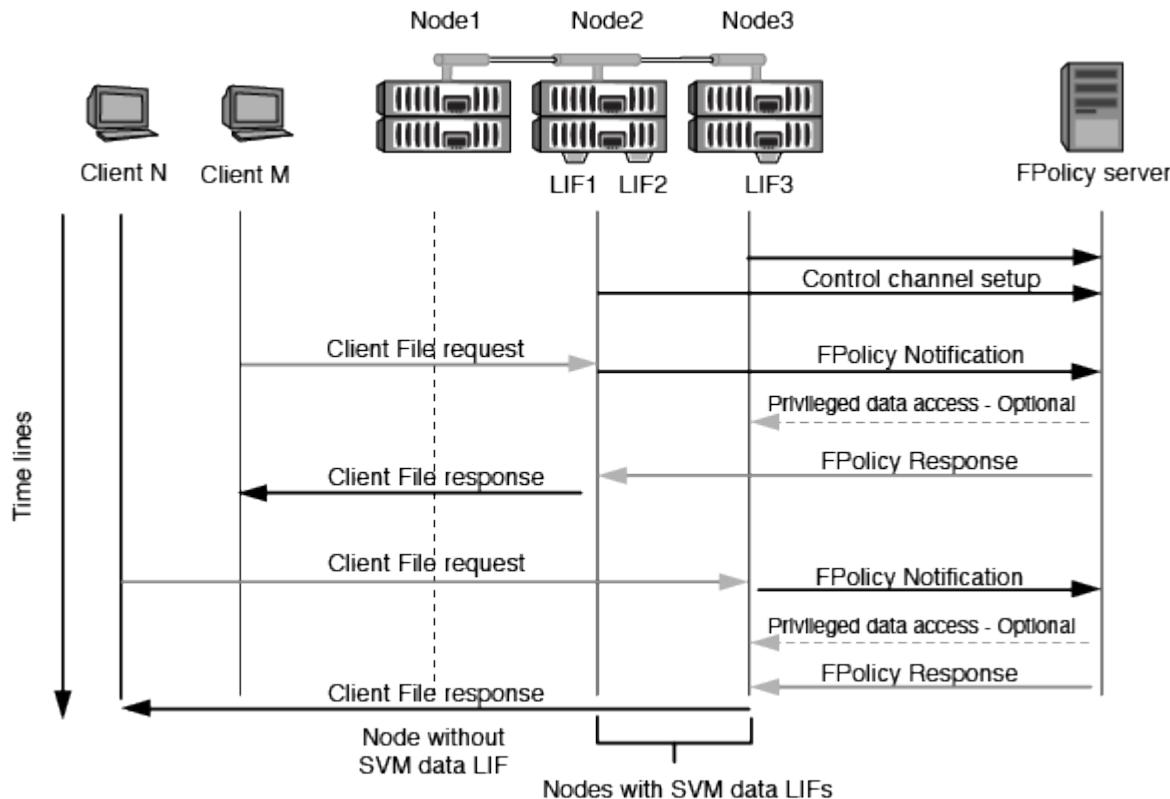

To properly plan your FPolicy configuration, you should understand what the node-to-external FPolicy server communication process is.

Every node that participates on each storage virtual machine (SVM) initiates a connection to an external FPolicy server (FPolicy server) using TCP/IP. Connections to the FPolicy servers are set up using node data LIFs; therefore, a participating node can set up a connection only if the node has an operational data LIF for the SVM.

Each FPolicy process on participating nodes attempts to establish a connection with the FPolicy server when the policy is enabled. It uses the IP address and port of the FPolicy external engine specified in the policy configuration.

The connection establishes a control channel from each of the nodes participating on each SVM to the FPolicy server through the data LIF. In addition, if IPv4 and IPv6 data LIF addresses are present on the same participating node, FPolicy attempts to establish connections for both IPv4 and IPv6. Therefore, in a scenario where the SVM extends over multiple nodes or if both IPv4 and IPv6 addresses are present, the FPolicy server must be ready for multiple control channel setup requests from the cluster after the FPolicy policy is enabled on the SVM.

For example, if a cluster has three nodes—Node1, Node2, and Node3—and SVM data LIFs are spread across only Node2 and Node3, control channels are initiated only from Node2 and Node3, irrespective of the distribution of data volumes. Say that Node2 has two data LIFs—LIF1 and LIF2—that belong to the SVM and that the initial connection is from LIF1. If LIF1 fails, FPolicy attempts to establish a control channel from LIF2.

== How FPolicy manages external communication during LIF migration or failover

Data LIFs can be migrated to data ports in the same node or to data ports on a remote node.

When a data LIF fails over or is migrated, a new control channel connection is made to the FPolicy server. FPolicy can then retry SMB and NFS client requests that timed out, with the result that new notifications are sent to the external FPolicy servers. The node rejects FPolicy server responses to original, timed-out SMB and NFS requests.

== How FPolicy manages external communication during node failover

If the cluster node that hosts the data ports used for FPolicy communication fails, ONTAP breaks the connection between the FPolicy server and the node.

The impact of cluster failover to the FPolicy server can be mitigated by configuring the LIF manager to migrate the data port used in FPolicy communication to another active node. After the migration is complete, a new connection is established using the new data port.

If the LIF manager is not configured to migrate the data port, the FPolicy server must wait for the failed node to come up. After the node is up, a new connection is initiated from that node with a new Session ID.

The FPolicy server detects broken connections with the keep-alive protocol message. The timeout for purging the session ID is determined when configuring FPolicy. The default keep-alive timeout is two minutes.

= How FPolicy services work across SVM namespaces

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

ONTAP provides a unified storage virtual machine (SVM) namespace. Volumes across the cluster are joined together by junctions to provide a single, logical file system. The FPolicy server is aware of the namespace topology and provides FPolicy services across the namespace.

The namespace is specific to and contained within the SVM; therefore, you can see the namespace only from the SVM context. Namespaces have the following characteristics:

- A single namespace exists in each SVM, with the root of the namespace being the root volume, represented in the namespace as slash (/).
- All other volumes have junction points below the root (/).
- Volume junctions are transparent to clients.
- A single NFS export can provide access to the complete namespace; otherwise, export policies can export specific volumes.
- SMB shares can be created on the volume or on qtrees within the volume, or on any directory within the namespace.
- The namespace architecture is flexible.

Examples of typical namespace architectures are as follows:

- A namespace with a single branch off of the root
- A namespace with multiple branches off of the root
- A namespace with multiple unbranched volumes off of the root

= FPolicy configuration types

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

There are two basic FPolicy configuration types. One configuration uses external FPolicy servers to process and act upon notifications. The other configuration does not use external FPolicy servers; instead, it uses the ONTAP internal, native FPolicy server for simple file blocking based on extensions.

- **External FPolicy server configuration**

The notification is sent to the FPolicy server, which screens the request and applies rules to determine whether the node should allow the requested file operation. For synchronous policies, the FPolicy server then sends a response to the node to either allow or block the requested file operation.

- **Native FPolicy server configuration**

The notification is screened internally. The request is allowed or denied based on file extension settings configured in the FPolicy scope.

== When to create a native FPolicy configuration

Native FPolicy configurations use the ONTAP internal FPolicy engine to monitor and block file operations based on the file's extension. This solution does not require external FPolicy servers (FPolicy servers). Using a native file blocking configuration is appropriate when this simple solution is all that is needed.

Native file blocking enables you to monitor any file operations that match configured operation and filtering events and then deny access to files with particular extensions. This is the default configuration.

This configuration provides a means to block file access based only on the file's extension. For example, to block files that contain `.mp3` extensions, you configure a policy to provide notifications for certain operations with target file extensions of `.mp3`. The policy is configured to deny `.mp3` file requests for operations that generate notifications.

The following applies to native FPolicy configurations:

- The same set of filters and protocols that are supported by FPolicy server-based file screening are also supported for native file blocking.
- Native file blocking and FPolicy server-based file screening applications can be configured at the same time.

To do so, you can configure two separate FPolicy policies for the storage virtual machine (SVM), with one configured for native file blocking and one configured for FPolicy server-based file screening.

- The native file blocking feature only screens files based on the extensions and not on the content of the file.
- In the case of symbolic links, native file blocking uses the file extension of the root file.

== When to create a configuration that uses external FPolicy servers

FPolicy configurations that use external FPolicy servers to process and manage notifications provide robust solutions for use cases where more than simple file blocking based on file extension is needed.

You should create a configuration that uses external FPolicy servers when you want to do such things as monitor and record file access events, provide quota services, perform file blocking based on criteria other than simple file extensions, provide data migration services using hierarchical storage management applications, or provide a fine-grained set of policies that monitor only a subset of data in the storage virtual machine (SVM).

= How FPolicy passthrough-read enhances usability for hierarchical storage management
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Passthrough-read enables the FPolicy server (functioning as the hierarchical storage management (HSM) server) to provide read access to offline files without having to recall the file from the secondary storage system to the primary storage system.

When an FPolicy server is configured to provide HSM to files residing on a SMB server, policy-based file migration occurs where the files are stored offline on secondary storage and only a stub file remains on primary storage. Even though a stub file appears as a normal file to clients, it is actually a sparse file that is the same size of the original file. The sparse file has the SMB offline bit set and points to the actual file that has been migrated to secondary storage.

Typically when a read request for an offline file is received, the requested content must be recalled back to primary storage and then accessed through primary storage. The need to recall data back to primary storage has several undesirable effects. Among the undesirable effects is the increased latency to client requests caused by the need to recall the content before responding to the request and the increased space consumption needed for recalled files on the primary storage.

FPolicy passthrough-read allows the HSM server (the FPolicy server) to provide read access to migrated, offline files without having to recall the file from the secondary storage system to the primary storage system. Instead of recalling the files back to primary storage, read requests can be serviced directly from secondary storage.

Copy Offload (ODX) is not supported with FPolicy passthrough-read operation.

Passthrough-read enhances usability by providing the following benefits:

- Read requests can be serviced even if the primary storage does not have sufficient space to recall requested data back to primary storage.
- Better capacity and performance management when a surge of data recall might occur, such as if a script or a backup solution needs to access many offline files.
- Read requests for offline files in Snapshot copies can be serviced.

Because Snapshot copies are read-only, the FPolicy server cannot restore the original file if the stub file is located in a Snapshot copy. Using passthrough-read eliminates this problem.

- Policies can be set up that control when read requests are serviced through access to the file on secondary storage and when the offline file should be recalled to primary storage.

For example, a policy can be created on the HSM server that specifies the number of times the offline file can be accessed in a specified period of time before the file is migrated back to primary storage. This type of policy avoids recalling files that are rarely accessed.

== How read requests are managed when FPolicy passthrough-read is enabled

You should understand how read requests are managed when FPolicy passthrough-read is enabled so that you can optimally configure connectivity between the storage virtual machine (SVM) and the FPolicy servers.

When FPolicy passthrough-read is enabled and the SVM receives a request for an offline file, FPolicy sends a notification to the FPolicy server (HSM server) through the standard connection channel.

After receiving the notification, the FPolicy server reads the data from the file path sent in the notification and sends the requested data to the SVM through the passthrough-read privileged data connection that is established between the SVM and the FPolicy server.

After the data is sent, the FPolicy server then responds to the read request as an ALLOW or DENY. Based on whether the read request is allowed or denied, ONTAP either sends the requested information or sends an error message to the client.

= Requirements, considerations, and best practices for configuring FPolicy

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Before you create and configure FPolicy configurations on your storage virtual machines (SVMs), you need to be aware of certain requirements, considerations, and best practices for configuring FPolicy.

== Ways to configure FPolicy

FPolicy features are configured either through the command line interface (CLI) or through APIs. This guide uses the CLI to create, manage, and monitor an FPolicy configuration on the cluster.

== Requirements for setting up FPolicy

Before you configure and enable FPolicy on your storage virtual machine (SVM), you need to be aware of certain requirements.

- All nodes in the cluster must be running a version of ONTAP that supports FPolicy.
- If you are not using the ONTAP native FPolicy engine, you must have external FPolicy servers (FPolicy servers) installed.
- The FPolicy servers must be installed on a server accessible from the data LIFs of the SVM where FPolicy policies are enabled.
- The IP address of the FPolicy server must be configured as a primary or secondary server in the FPolicy policy external engine configuration.
- If the FPolicy servers access data over a privileged data channel, the following additional requirements must be met:
 - SMB must be licensed on the cluster.

Privileged data access is accomplished using SMB connections.

- A user credential must be configured for accessing files over the privileged data channel.
- The FPolicy server must run under the credentials configured in the FPolicy configuration.
- All data LIFs used to communicate with the FPolicy servers must be configured to have `cifs` as one of the allowed protocols.

This includes the LIFs used for passthrough-read connections.

== Best practices and recommendations when setting up FPolicy

When setting up FPolicy on storage virtual machines (SVMs), you need to be familiar with configuration best practices and recommendations to ensure that your FPolicy configuration provides robust monitoring performance and results that meet your requirements.

- External FPolicy servers (FPolicy servers) should be placed in close proximity to the cluster with high-bandwidth connectivity to provide minimal latency and high-bandwidth connectivity.
- The FPolicy external engine should be configured with more than one FPolicy server to provide resiliency and high availability of FPolicy server notification processing, especially if policies are configured for synchronous screening.

- It is recommended that you disable the FPolicy policy before making any configuration changes.

For example, if you want to add or modify an IP address in the FPolicy external engine configured for the enabled policy, you should first disable the policy.

- The cluster node-to-FPolicy server ratio should be optimized to ensure that FPolicy servers are not overloaded, which can introduce latencies when the SVM responds to client requests.

The optimal ratio depends on the application for which the FPolicy server is being used.

== Passthrough-read upgrade and revert considerations

There are certain upgrade and revert considerations that you must know about before upgrading to an ONTAP release that supports passthrough-read or before reverting to a release that does not support passthrough-read.

==== Upgrading

After all nodes are upgraded to a version of ONTAP that supports FPolicy passthrough-read, the cluster is capable of using the passthrough-read functionality; however, passthrough-read is disabled by default on existing FPolicy configurations. To use passthrough-read on existing FPolicy configurations, you must disable the FPolicy policy and modify the configuration, and then reenable the configuration.

==== Reverting

Before reverting to a version of ONTAP that does not support FPolicy passthrough-read, the following conditions must be met:

- All the policies using passthrough-read must be disabled, and then the affected configurations must be modified so that they do not use passthrough-read.
- FPolicy functionality must be disabled on the cluster by disabling every FPolicy policy on the cluster.

= What the steps for setting up an FPolicy configuration are

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Before FPolicy can monitor file access, an FPolicy configuration must be created and enabled on the storage virtual machine (SVM) for which FPolicy services are required.

The steps for setting up and enabling an FPolicy configuration on the SVM are as follows:

1. Create an FPolicy external engine.

The FPolicy external engine identifies the external FPolicy servers (FPolicy servers) that are associated with a specific FPolicy configuration. If the internal “native” FPolicy engine is used to create a native file-blocking configuration, you do not need to create an FPolicy external engine.

2. Create an FPolicy event.

An FPolicy event describes what the FPolicy policy should monitor. Events consist of the protocols and file operations to monitor, and can contain a list of filters. Events use filters to narrow the list of monitored events for which the FPolicy external engine must send notifications. Events also specify

whether the policy monitors volume operations.

3. Create an FPolicy policy.

The FPolicy policy is responsible for associating, with the appropriate scope, the set of events that need to be monitored and for which of the monitored events notifications must be sent to the designated FPolicy server (or to the native engine if no FPolicy servers are configured). The policy also defines whether the FPolicy server is allowed privileged access to the data for which it receives notifications. An FPolicy server needs privileged access if the server needs to access the data. Typical use cases where privileged access is needed include file blocking, quota management, and hierarchical storage management. The policy is where you specify whether the configuration for this policy uses an FPolicy server or the internal “native” FPolicy server.

A policy specifies whether screening is mandatory. If screening is mandatory and all FPolicy servers are down or no response is received from the FPolicy servers within a defined timeout period, then file access is denied.

A policy’s boundaries are the SVM. A policy cannot apply to more than one SVM. However, a specific SVM can have multiple FPolicy policies, each with the same or different combination of scope, event, and external server configurations.

4. Configure the policy scope.

The FPolicy scope determines which volumes, shares, or export-policies the policy acts on or excludes from monitoring. A scope also determines which file extensions should be included or excluded from FPolicy monitoring.

Exclude lists take precedence over include lists.

5. Enable the FPolicy policy.

When the policy is enabled, the control channels and, optionally, the privileged data channels are connected. The FPolicy process on the nodes on which the SVM participates begin monitoring file and folder access and, for events that match configured criteria, sends notifications to the FPolicy servers (or to the native engine if no FPolicy servers are configured).

If the policy uses native file blocking, an external engine is not configured or associated with the policy.

= Plan the FPolicy configuration

= Plan the FPolicy external engine configuration

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Before you configure the FPolicy external engine (external engine), you must understand what it means to create an external engine and which configuration parameters are available. This information helps you to determine which values to set for each parameter.

== Information that is defined when creating the FPolicy external engine

The external engine configuration defines the information that FPolicy needs to make and manage connections to the external FPolicy servers (FPolicy servers), including the following information:

- storage virtual machine (SVM) name
- Engine name
- The IP addresses of the primary and secondary FPolicy servers and the TCP port number to use when making the connection to the FPolicy servers
- Whether the engine type is asynchronous or synchronous
- How to authenticate the connection between the node and the FPolicy server

If you choose to configure mutual SSL authentication, then you must also configure parameters that provide SSL certificate information.

- How to manage the connection using various advanced privilege settings

This includes parameters that define such things as timeout values, retry values, keep-alive values, maximum request values, sent and receive buffer size values, and session timeout values.

The `vserver fpolicy policy external-engine create` command is used to create an FPolicy external engine.

== What the basic external engine parameters are

You can use the following table of basic FPolicy configuration parameters to help you plan your configuration:

Type of information	Option
<p>SVM</p> <p>Specifies the SVM name that you want to associate with this external engine.</p> <p>Each FPolicy configuration is defined within a single SVM. The external engine, policy event, policy scope, and policy that combine together to create an FPolicy policy configuration must all be associated with the same SVM.</p>	<code>-vserver vserver_name</code>

<p>Engine name</p> <p>Specifies the name to assign to the external engine configuration. You must specify the external engine name later when you create the FPolicy policy. This associates the external engine with the policy.</p> <p>The name can be up to 256 characters long.</p> <p> The name should be up to 200 characters long if configuring the external engine name in a MetroCluster or SVM disaster recovery configuration.</p> <p>The name can contain any combination of the following ASCII-range characters:</p> <ul style="list-style-type: none"> • a through z • A through Z • 0 through 9 • “_”, “-”, and “.” 	<pre>-engine-name engine_name</pre>
<p>Primary FPolicy servers</p> <p>Specifies the primary FPolicy servers to which the node sends notifications for a given FPolicy policy. The value is specified as a comma-delimited list of IP addresses.</p> <p>If more than one primary server IP address is specified, every node on which the SVM participates creates a control connection to every specified primary FPolicy server at the time the policy is enabled. If you configure multiple primary FPolicy servers, notifications are sent to the FPolicy servers in a round-robin fashion.</p> <p>If the external engine is used in a MetroCluster or SVM disaster recovery configuration, you should specify the IP addresses of the FPolicy servers at the source site as primary servers. The IP addresses of the FPolicy servers at the destination site should be specified as secondary servers.</p>	<pre>-primary-servers IP_address,...</pre>
<p>Port number</p> <p>Specifies the port number of the FPolicy service.</p>	<pre>-port integer</pre>

<p>Secondary FPolicy servers</p> <p>Specifies the secondary FPolicy servers to which to send file access events for a given FPolicy policy. The value is specified as a comma-delimited list of IP addresses.</p> <p>Secondary servers are used only when none of the primary servers are reachable. Connections to secondary servers are established when the policy is enabled, but notifications are sent to secondary servers only if none of the primary servers are reachable. If you configure multiple secondary servers, notifications are sent to the FPolicy servers in a round-robin fashion.</p>	<pre>-secondary-servers IP_address,...</pre>
<p>External engine type</p> <p>Specifies whether the external engine operates in synchronous or asynchronous mode. By default, FPolicy operates in synchronous mode.</p> <p>When set to <code>synchronous</code>, file request processing sends a notification to the FPolicy server, but then does not continue until after receiving a response from the FPolicy server. At that point, request flow either continues or processing results in denial, depending on whether the response from the FPolicy server permits the requested action.</p> <p>When set to <code>asynchronous</code>, file request processing sends a notification to the FPolicy server, and then continues.</p>	<pre>-extern-engine-type external_engine_type The value for this parameter can be one of the following:</pre> <ul style="list-style-type: none"> • <code>synchronous</code> • <code>asynchronous</code>
<p>SSL option for communication with FPolicy server</p> <p>Specifies the SSL option for communication with the FPolicy server. This is a required parameter. You can choose one of the options based on the following information:</p> <ul style="list-style-type: none"> • When set to <code>no-auth</code>, no authentication takes place. The communication link is established over TCP. • When set to <code>server-auth</code>, the SVM authenticates the FPolicy server using SSL server authentication. • When set to <code>mutual-auth</code>, mutual authentication takes place between the SVM and the FPolicy server; the SVM authenticates the FPolicy server, and the FPolicy server authenticates the SVM. <p>If you choose to configure mutual SSL authentication, then you must also configure the <code>-certificate-common-name</code>, <code>-certificate-serial</code>, and <code>-certificate-ca</code> parameters.</p>	<pre>-ssl-option {no-auth server-auth mutual- auth}</pre>

Certificate FQDN or custom common name	-certificate-common-name text
Specifies the certificate name used if SSL authentication between the SVM and the FPolicy server is configured. You can specify the certificate name as an FQDN or as a custom common name. If you specify mutual-auth for the -ssl-option parameter, you must specify a value for the -certificate-common-name parameter.	
Certificate serial number	-certificate-serial text
Specifies the serial number of the certificate used for authentication if SSL authentication between the SVM and the FPolicy server is configured. If you specify mutual-auth for the -ssl-option parameter, you must specify a value for the -certificate-serial parameter.	

== What the advanced external engine options are

You can use the following table of advanced FPolicy configuration parameters as you plan whether to customize your configuration with advanced parameters. You use these parameters to modify communication behavior between the cluster nodes and the FPolicy servers:

Type of information	Option
Timeout for canceling a request Specifies the time interval in hours (h), minutes (m), or seconds (s) that the node waits for a response from the FPolicy server. If the timeout interval passes, the node sends a cancel request to the FPolicy server. The node then sends the notification to an alternate FPolicy server. This timeout helps in handling an FPolicy server that is not responding, which can improve SMB/NFS client response. Also, canceling requests after a timeout period can help in releasing system resources because the notification request is moved from a down/bad FPolicy server to an alternate FPolicy server. The range for this value is 0 through 100. If the value is set to 0, the option is disabled and cancel request messages are not sent to the FPolicy server. The default is 20s.	-reqs-cancel-timeout integer[h m s]

<i>Timeout for aborting a request</i>	-reqs-abort-timeout `integer[h m s]
Specifies the timeout in hours (h), minutes (m), or seconds (s) for aborting a request. The range for this value is 0 through 200.	
<i>Interval for sending status requests</i>	-status-req-interval integer[h m s]
Specifies the interval in hours (h), minutes (m), or seconds (s) after which a status request is sent to the FPolicy server. The range for this value is 0 through 50. If the value is set to 0, the option is disabled and status request messages are not sent to the FPolicy server. The default is 10s.	
<i>Maximum outstanding requests on the FPolicy server</i>	-max-server-reqs integer
Specifies the maximum number of outstanding requests that can be queued on the FPolicy server. The range for this value is 1 through 10000. The default is 50.	
<i>Timeout for disconnecting a nonresponsive FPolicy server</i>	-server-progress -timeout integer[h m s]
Specifies the time interval in hours (h), minutes (m), or seconds (s) after which the connection to the FPolicy server is terminated. The connection is terminated after the timeout period only if the FPolicy server's queue contains the maximum allowed requests and no response is received within the timeout period. The maximum allowed number of requests is either 50 (the default) or the number specified by the max-server-reqs- parameter. The range for this value is 1 through 100. The default is 60s.	
<i>Interval for sending keep-alive messages to the FPolicy server</i>	-keep-alive-interval- integer[h m s]
Specifies the time interval in hours (h), minutes (m), or seconds (s) at which keep-alive messages are sent to the FPolicy server. Keep-alive messages detect half-open connections. The range for this value is 10 through 600. If the value is set to 0, the option is disabled and keep-alive messages are prevented from being sent to the FPolicy servers. The default is 120s.	

<i>Maximum reconnect attempts</i>	-max-connection -retries integer
<p>Specifies the maximum number of times the SVM attempts to reconnect to the FPolicy server after the connection has been broken.</p> <p>The range for this value is 0 through 20. The default is 5.</p>	
<i>Receive buffer size</i>	-recv-buffer-size integer
<p>Specifies the receive buffer size of the connected socket for the FPolicy server.</p> <p>The default value is set to 256 kilobytes (Kb). When the value is set to 0, the size of the receive buffer is set to a value defined by the system.</p> <p>For example, if the default receive buffer size of the socket is 65536 bytes, by setting the tunable value to 0, the socket buffer size is set to 65536 bytes. You can use any non-default value to set the size (in bytes) of the receive buffer.</p>	
<i>Send buffer size</i>	-send-buffer-size integer
<p>Specifies the send buffer size of the connected socket for the FPolicy server.</p> <p>The default value is set to 256 kilobytes (Kb). When the value is set to 0, the size of the send buffer is set to a value defined by the system.</p> <p>For example, if the default send buffer size of the socket is set to 65536 bytes, by setting the tunable value to 0, the socket buffer size is set to 65536 bytes. You can use any non-default value to set the size (in bytes) of the send buffer.</p>	
<i>Timeout for purging a session ID during reconnection</i>	-session-timeout [integerh][integerm][integers]
<p>Specifies the interval in hours (h), minutes (m), or seconds (s) after which a new session ID is sent to the FPolicy server during reconnection attempts.</p> <p>If the connection between the storage controller and the FPolicy server is terminated and reconnection is made within the -session-timeout interval, the old session ID is sent to FPolicy server so that it can send responses for old notifications.</p> <p>The default value is set to 10 seconds.</p>	

= Additional information about configuring FPolicy external engines to use SSL authenticated connections
 :icons: font
 :relative_path: ./nas-audit/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You need to know some additional information if you want to configure the FPolicy

external engine to use SSL when connecting to FPolicy servers.

== SSL server authentication

If you choose to configure the FPolicy external engine for SSL server authentication, before creating the external engine, you must install the public certificate of the certificate authority (CA) that signed the FPolicy server certificate.

== Mutual authentication

If you configure FPolicy external engines to use SSL mutual authentication when connecting storage virtual machine (SVM) data LIFs to external FPolicy servers, before creating the external engine, you must install the public certificate of the CA that signed the FPolicy server certificate along with the public certificate and key file for authentication of the SVM. You must not delete this certificate while any FPolicy policies are using the installed certificate.

If the certificate is deleted while FPolicy is using it for mutual authentication when connecting to an external FPolicy server, you cannot reenable a disabled FPolicy policy that uses that certificate. The FPolicy policy cannot be reenabled in this situation even if a new certificate with the same settings is created and installed on the SVM.

If the certificate has been deleted, you need to install a new certificate, create new FPolicy external engines that use the new certificate, and associate the new external engines with the FPolicy policy that you want to reenable by modifying the FPolicy policy.

== Install certificates for SSL

The public certificate of the CA that is used to sign the FPolicy server certificate is installed by using the security certificate install command with the -type parameter set to `client_ca`. The private key and public certificate required for authentication of the SVM is installed by using the security certificate install command with the -type parameter set to `server`.

= Certificates do not replicate in SVM disaster recovery relationships with a non-ID-preserve configuration

:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Security certificates used for SSL authentication when making connections to FPolicy servers do not replicate to SVM disaster recovery destinations with non-ID-preserve configurations. Although the FPolicy external-engine configuration on the SVM is replicated, security certificates are not replicated. You must manually install the security certificates on the destination.

When you set up the SVM disaster recovery relationship, the value you select for the `-identity-preserve` option of the `snapmirror create` command determines the configuration details that are replicated in the destination SVM.

If you set the `-identity-preserve` option to `true` (ID-preserve), all of the FPolicy configuration details are replicated, including the security certificate information. You must install the security certificates on the destination only if you set the option to `false` (non-ID-preserve).

= Restrictions for cluster-scoped FPolicy external engines with MetroCluster and SVM disaster recovery configurations

```
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

You can create a cluster-scoped FPolicy external engine by assigning the cluster storage virtual machine (SVM) to the external engine. However, when creating a cluster-scoped external engine in a MetroCluster or SVM disaster recovery configuration, there are certain restrictions when choosing the authentication method that the SVM uses for external communication with the FPolicy server.

There are three authentication options that you can choose when creating external FPolicy servers: no authentication, SSL server authentication, and SSL mutual authentication. Although there are no restrictions when choosing the authentication option if the external FPolicy server is assigned to a data SVM, there are restrictions when creating a cluster-scoped FPolicy external engine:

Configuration	Permitted?
MetroCluster or SVM disaster recovery and a cluster-scoped FPolicy external engine with no authentication (SSL is not configured)	Yes
MetroCluster or SVM disaster recovery and a cluster-scoped FPolicy external engine with SSL server or SSL mutual authentication	No

- If a cluster-scoped FPolicy external engine with SSL authentication exists and you want to create a MetroCluster or SVM disaster recovery configuration, you must modify this external engine to use no authentication or remove the external engine before you can create the MetroCluster or SVM disaster recovery configuration.
- If the MetroCluster or SVM disaster recovery configuration already exists, ONTAP prevents you from creating a cluster-scoped FPolicy external engine with SSL authentication.

= Complete the FPolicy external engine configuration worksheet

```
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/
```

You can use this worksheet to record the values that you need during the FPolicy external engine configuration process. If a parameter value is required, you need to determine what value to use for those parameters before you configure the external engine.

== Information for a basic external engine configuration

You should record whether you want to include each parameter setting in the external engine configuration and then record the value for the parameters that you want to include.

Type of information	Required	Include	Your values
Storage virtual machine (SVM) name	Yes	Yes	
Engine name	Yes	Yes	

Primary FPolicy servers	Yes	Yes	
Port number	Yes	Yes	
Secondary FPolicy servers	No		
External engine type	No		
SSL option for communication with external FPolicy server	Yes	Yes	
Certificate FQDN or custom common name	No		
Certificate serial number	No		
Certificate authority	No		

== Information for advanced external engine parameters

To configure an external engine with advanced parameters, you must enter the configuration command while in advanced privilege mode.

Type of information	Required	Include	Your values
Timeout for canceling a request	No		
Timeout for aborting a request	No		
Interval for sending status requests	No		
Maximum outstanding requests on the FPolicy server	No		
Timeout for disconnecting a nonresponsive FPolicy server	No		
Interval for sending keep-alive messages to the FPolicy server	No		
Maximum reconnect attempts	No		
Receive buffer size	No		
Send buffer size	No		

Timeout for purging a session ID during reconnection	No		
--	----	--	--

= Plan the FPolicy event configuration

= Plan the FPolicy event configuration overview

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Before you configure FPolicy events, you must understand what it means to create an FPolicy event. You must determine which protocols you want the event to monitor, which events to monitor, and which event filters to use. This information helps you plan the values that you want to set.

== What it means to create an FPolicy event

Creating the FPolicy event means defining information that the FPolicy process needs to determine what file access operations to monitor and for which of the monitored events notifications should be sent to the external FPolicy server. The FPolicy event configuration defines the following configuration information:

- Storage virtual machine (SVM) name
- Event name
- Which protocols to monitor

FPolicy can monitor SMB, NFSv3, and NFSv4 file access operations.

- Which file operations to monitor

Not all file operations are valid for each protocol.

- Which file filters to configure

Only certain combinations of file operations and filters are valid. Each protocol has its own set of supported combinations.

- Whether to monitor volume mount and unmount operations

There is a dependency with three of the parameters (-protocol, -file-operations, -filters). The following combinations are valid for the three parameters:

- You can specify the -protocol and -file-operations parameters.
- You can specify all three of the parameters.
- You can specify none of the parameters.

== What the FPolicy event configuration contains

You can use the following list of available FPolicy event configuration parameters to help you plan your configuration:

Type of information	Option
SVM Specifies the SVM name that you want to associate with this FPolicy event. Each FPolicy configuration is defined within a single SVM. The external engine, policy event, policy scope, and policy that combine together to create an FPolicy policy configuration must all be associated with the same SVM.	-vserver vserver_name
<i>Event name</i> Specifies the name to assign to the FPolicy event. When you create the FPolicy policy you associate the FPolicy event with the policy using the event name. The name can be up to 256 characters long.  The name should be up to 200 characters long if configuring the event in a MetroCluster or SVM disaster recovery configuration. The name can contain any combination of the following ASCII-range characters: <ul style="list-style-type: none"> • a through z • A through Z • 0 through 9 • " _ ", "-", and "." 	-event-name event_name
<i>Protocol</i> Specifies which protocol to configure for the FPolicy event. The list for -protocol can include one of the following values: <ul style="list-style-type: none"> • cifs • nfsv3 • nfsv4  If you specify -protocol, then you must specify a valid value in the -file-operations parameter. As the protocol version changes, the valid values might change.	-protocol protocol

File operations

Specifies the list of file operations for the FPolicy event.

The event checks the operations specified in this list from all client requests using the protocol specified in the `-protocol` parameter. You can list one or more file operations by using a comma-delimited list. The list for `-file-operations` can include one or more of the following values:

- `close` for file close operations
- `create` for file create operations
- `create-dir` for directory create operations
- `delete` for file delete operations
- `delete_dir` for directory delete operations
- `getattr` for get attribute operations
- `link` for link operations
- `lookup` for lookup operations
- `open` for file open operations
- `read` for file read operations
- `write` for file write operations
- `rename` for file rename operations
- `rename_dir` for directory rename operations
- `setattr` for set attribute operations
- `symlink` for symbolic link operations

If you specify `-file-operations`, then you must specify a valid protocol in the `-protocol` parameter.

`-file-operations`
`file_operations,...`

Filters

`-filters filter, ...`

Specifies the list of filters for a given file operation for the specified protocol. The values in the `-filters` parameter are used to filter client requests. The list can include one or more of the following:

If you specify the `-filters` parameter, then you must also specify valid values for the `-file-operations` and `-protocol` parameters.

- `monitor-ads` option to filter the client request for alternate data stream.
- `close-with-modification` option to filter the client request for close with modification.
- `close-without-modification` option to filter the client request for close without modification.
- `first-read` option to filter the client request for first read.
- `first-write` option to filter the client request for first write.
- `offline-bit` option to filter the client request for offline bit set.

Setting this filter results in the FPolicy server receiving notification only when offline files are accessed.

- `open-with-delete-intent` option to filter the client request for open with delete intent.

Setting this filter results in the FPolicy server receiving notification only when an attempt is made to open a file with the intent to delete it. This is used by file systems when the `FILE_DELETE_ON_CLOSE` flag is specified.

- `open-with-write-intent` option to filter client request for open with write intent.

Setting this filter results in the FPolicy server receiving notification only when an attempt is made to open a file with the intent to write something in it.

- `write-with-size-change` option to filter the client request for write with size change.

Filters continued	-filters filter, ...
<ul style="list-style-type: none"> • <code>setattr-with-owner-change</code> option to filter the client <code>setattr</code> requests for changing owner of a file or a directory. • <code>setattr-with-group-change</code> option to filter the client <code>setattr</code> requests for changing the group of a file or a directory. • <code>setattr-with-sacl-change</code> option to filter the client <code>setattr</code> requests for changing the SACL on a file or a directory. <p>This filter is available only for the SMB and NFSv4 protocols.</p> <ul style="list-style-type: none"> • <code>setattr-with-dacl-change</code> option to filter the client <code>setattr</code> requests for changing the DACL on a file or a directory. <p>This filter is available only for the SMB and NFSv4 protocols.</p> <ul style="list-style-type: none"> • <code>setattr-with-modify-time-change</code> option to filter the client <code>setattr</code> requests for changing the modification time of a file or a directory. • <code>setattr-with-access-time-change</code> option to filter the client <code>setattr</code> requests for changing the access time of a file or a directory. • <code>setattr-with-creation-time-change</code> option to filter the client <code>setattr</code> requests for changing the creation time of a file or a directory. <p>This option is available only for the SMB protocol.</p> <ul style="list-style-type: none"> • <code>setattr-with-mode-change</code> option to filter the client <code>setattr</code> requests for changing the mode bits on a file or a directory. • <code>setattr-with-size-change</code> option to filter the client <code>setattr</code> requests for changing the size of a file. • <code>setattr-with-allocation-size-change</code> option to filter the client <code>setattr</code> requests for changing the allocation size of a file. <p>This option is available only for the SMB protocol.</p> <ul style="list-style-type: none"> • <code>exclude-directory</code> option to filter the client requests for directory operations. <p>When this filter is specified, the directory operations are not monitored.</p>	
<i>Is volume operation required</i>	<code>-volume-operation {true false}</code>
Specifies whether monitoring is required for volume mount and unmount operations. The default is <code>false</code> .	

= List of supported file operation and filter combinations that FPolicy can monitor for SMB
 :icons: font
 :relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

When you configure your FPolicy event, you need to be aware that only certain combinations of file operations and filters are supported for monitoring SMB file access operations.

The list of supported file operation and filter combinations for FPolicy monitoring of SMB file access events is provided in the following table:

Supported file operations	Supported filters
close	monitor-ads, offline-bit, close-with-modification, close-without-modification, close-with-read, exclude-directory
create	monitor-ads, offline-bit
create_dir	Currently no filter is supported for this file operation.
delete	monitor-ads, offline-bit
delete_dir	Currently no filter is supported for this file operation.
getattr	offline-bit, exclude-dir
open	monitor-ads, offline-bit, open-with-delete-intent, open-with-write-intent, exclude-dir
read	monitor-ads, offline-bit, first-read
write	monitor-ads, offline-bit, first-write, write-with-size-change
rename	monitor-ads, offline-bit
rename_dir	Currently no filter is supported for this file operation.
setattr	monitor-ads, offline-bit, setattr_with_owner_change, setattr_with_group_change, setattr_with_mode_change, setattr_with_sacl_change, setattr_with_dacl_change, setattr_with_modify_time_change, setattr_with_access_time_change, setattr_with_creation_time_change, setattr_with_size_change, setattr_with_allocation_size_change, exclude_directory

= Supported file operation and filter combinations that FPolicy can monitor for NFSv3

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/

When you configure your FPolicy event, you need to be aware that only certain

combinations of file operations and filters are supported for monitoring NFSv3 file access operations.

The list of supported file operation and filter combinations for FPolicy monitoring of NFSv3 file access events is provided in the following table:

Supported file operations	Supported filters
create	offline-bit
create_dir	Currently no filter is supported for this file operation.
delete	offline-bit
delete_dir	Currently no filter is supported for this file operation.
link	offline-bit
lookup	offline-bit, exclude-dir
read	offline-bit, first-read
write	offline-bit, first-write, write-with-size-change
rename	offline-bit
rename_dir	Currently no filter is supported for this file operation.
setattr	offline-bit, setattr_with_owner_change, setattr_with_group_change, setattr_with_mode_change, setattr_with_modify_time_change, setattr_with_access_time_change, setattr_with_size_change, exclude_directory
symlink	offline-bit

= Supported file operation and filter combinations that FPolicy can monitor for NFSv4

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

When you configure your FPolicy event, you need to be aware that only certain combinations of file operations and filters are supported for monitoring NFSv4 file access operations.

The list of supported file operation and filter combinations for FPolicy monitoring of NFSv4 file access events is provided in the following table:

Supported file operations	Supported filters
---------------------------	-------------------

close	offline-bit, exclude-directory
create	offline-bit
create_dir	Currently no filter is supported for this file operation.
delete	offline-bit
delete_dir	Currently no filter is supported for this file operation.
getattr	offline-bit, exclude-directory
link	offline-bit
lookup	offline-bit, exclude-directory
open	offline-bit, exclude-directory
read	offline-bit, first-read
write	offline-bit, first-write, write-with-size-change
rename	offline-bit
rename_dir	Currently no filter is supported for this file operation.
setattr	offline-bit, setattr_with_owner_change, setattr_with_group_change, setattr_with_mode_change, setattr_with_sacl_change, setattr_with_dacl_change, setattr_with_modify_time_change, setattr_with_access_time_change, setattr_with_size_change, exclude_directory
symlink	offline-bit

= Complete the FPolicy event configuration worksheet

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use this worksheet to record the values that you need during the FPolicy event configuration process. If a parameter value is required, you need to determine what value to use for those parameters before you configure the FPolicy event.

You should record whether you want to include each parameter setting in the FPolicy event configuration and then record the value for the parameters that you want to include.

Type of information	Required	Include	Your values
Storage virtual machine (SVM) name	Yes	Yes	
Event name	Yes	Yes	
Protocol	No		
File operations	No		
Filters	No		
Volume operation	No		

= Plan the FPolicy policy configuration

= Plan the FPolicy policy configuration overview

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Before you configure the FPolicy policy, you must understand which parameters are required when creating the policy as well as why you might want to configure certain optional parameters. This information helps you to determine which values to set for each parameter.

When creating an FPolicy policy you associate the policy with the following:

- The storage virtual machine (SVM)
- One or more FPolicy events
- An FPolicy external engine

You can also configure several optional policy settings.

== What the FPolicy policy configuration contains

You can use the following list of available FPolicy policy required and optional parameters to help you plan your configuration:

Type of information	Option	Required	Default
<i>SVM name</i> Specifies the name of the SVM on which you want to create an FPolicy policy.	-vserver vserver_name	Yes	None

<p><i>Policy name</i></p> <p>Specifies the name of the FPolicy policy.</p> <p>The name can be up to 256 characters long.</p> <p> The name should be up to 200 characters long if configuring the policy in a MetroCluster or SVM disaster recovery configuration.</p> <p>The name can contain any combination of the following ASCII-range characters:</p> <ul style="list-style-type: none"> • a through z • A through Z • 0 through 9 • “_”, “-”, and “.” 	<p>-policy-name policy_name</p>	<p>Yes</p>	<p>None</p>
<p><i>Event names</i></p> <p>Specifies a comma-delimited list of events to associate with the FPolicy policy.</p> <ul style="list-style-type: none"> • You can associate more than one event to a policy. • An event is specific to a protocol. • You can use a single policy to monitor file access events for more than one protocol by creating an event for each protocol that you want the policy to monitor, and then associating the events to the policy. • The events must already exist. 	<p>-events event_name, ...</p>	<p>Yes</p>	<p>None</p>

<p>External engine name</p> <p>Specifies the name of the external engine to associate with the FPolicy policy.</p> <ul style="list-style-type: none"> • An external engine contains information required by the node to send notifications to an FPolicy server. • You can configure FPolicy to use the ONTAP native external engine for simple file blocking or to use an external engine that is configured to use external FPolicy servers (FPolicy servers) for more sophisticated file blocking and file management. • If you want to use the native external engine, you can either not specify a value for this parameter or you can specify <code>native</code> as the value. • If you want to use FPolicy servers, the configuration for the external engine must already exist. 	<code>-engine engine_name</code>	Yes (unless the policy uses the internal ONTAP native engine)	native
<p>Is mandatory screening required</p> <p>Specifies whether mandatory file access screening is required.</p> <ul style="list-style-type: none"> • The mandatory screening setting determines what action is taken on a file access event in a case when all primary and secondary servers are down or no response is received from the FPolicy servers within a given timeout period. • When set to <code>true</code>, file access events are denied. • When set to <code>false</code>, file access events are allowed. 	<code>-is-mandatory {true false}</code>	No	true

Allow privileged access	-allow -privileged -access {yes no}	No (unless passthrough-read is enabled)	no
<p>Specifies whether you want the FPolicy server to have privileged access to the monitored files and folders by using a privileged data connection.</p> <p>If configured, FPolicy servers can access files from the root of the SVM containing the monitored data using the privileged data connection.</p> <p>For privileged data access, SMB must be licensed on the cluster and all the data LIFs used to connect to the FPolicy servers must be configured to have <code>cifs</code> as one of the allowed protocols.</p> <p>If you want to configure the policy to allow privileged access, you must also specify the user name for the account that you want the FPolicy server to use for privileged access.</p>			

<p>Allow passthrough-read</p> <p>Specifies whether the FPolicy servers can provide passthrough-read services for files that have been archived to secondary storage (offline files) by the FPolicy servers:</p> <ul style="list-style-type: none"> • Passthrough-read is a way to read data for offline files without restoring the data to the primary storage. <p>Passthrough-read reduces response latencies because there is no need to recall files back to primary storage before responding to the read request. Additionally, passthrough-read optimizes storage efficiency by eliminating the need to consume primary storage space with files that are recalled solely to satisfy read requests.</p> <ul style="list-style-type: none"> • When enabled, the FPolicy servers provide the data for the file over a separate privileged data channel opened specifically for passthrough-reads. • If you want to configure passthrough-read, the policy must also be configured to allow privileged access. 	<p>-is -passthrough -read-enabled {true false}</p>	<p>No</p>	<p>false</p>
--	--	-----------	--------------

= Requirement for FPolicy scope configurations if the FPolicy policy uses the native engine

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

If you configure the FPolicy policy to use the native engine, there is a specific requirement for how you define the FPolicy scope configured for the policy.

The FPolicy scope defines the boundaries on which the FPolicy policy applies, for example whether the FPolicy applies to specified volumes or shares. There are a number of parameters that further restrict the scope to which the FPolicy policy applies. One of these parameters, `-is-file-extension-check-on-directories-enabled`, specifies whether to check file extensions on directories. The default value is `false`, which means that file extensions on directories are not checked.

When an FPolicy policy that uses the native engine is enabled on a share or volume and the `-is-file-extension-check-on-directories-enabled` parameter is set to `false` for the scope of the policy, directory access is denied. With this configuration, because the file extensions are not checked for directories, any directory operation is denied if it falls under the scope of the policy.

To ensure that directory access succeeds when using the native engine, you must set the `-is-file-extension-check-on-directories-enabled` parameter to true when creating the scope.

With this parameter set to true, extension checks happen for directory operations and the decision whether to allow or deny access is taken based on the extensions included or excluded in the FPolicy scope configuration.

= Complete the FPolicy policy worksheet

:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use this worksheet to record the values that you need during the FPolicy policy configuration process. You should record whether you want to include each parameter setting in the FPolicy policy configuration and then record the value for the parameters that you want to include.

Type of information	Include	Your values
Storage virtual machine (SVM) name	Yes	
Policy name	Yes	
Event names	Yes	
External engine name		
Is mandatory screening required?		
Allow privileged access		
Privileged user name		
Is passthrough-read enabled?		

= Plan the FPolicy scope configuration

= Plan the FPolicy scope configuration overview

:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

Before you configure the FPolicy scope, you must understand what it means to create a scope. You must understand what the scope configuration contains. You also need to understand what the scope rules of precedence are. This information can help you plan the values that you want to set.

-- What it means to create an FPolicy scope

Creating the FPolicy scope means defining the boundaries on which the FPolicy policy applies. The storage virtual machine (SVM) is the basic boundary. When you create a scope for an FPolicy policy, you must define the FPolicy policy to which it will apply, and you must designate to which SVM you want to apply the scope.

There are a number of parameters that further restrict the scope within the specified SVM. You can restrict the scope by specifying what to include in the scope or by specifying what to exclude from the scope. After you apply a scope to an enabled policy, policy event checks get applied to the scope defined by this command.

Notifications are generated for file access events where matches are found in the “include” options. Notifications are not generated for file access events where matches are found in the “exclude” options.

The FPolicy scope configuration defines the following configuration information:

- SVM name
- Policy name
- The shares to include or exclude from what gets monitored
- The export policies to include or exclude from what gets monitored
- The volumes to include or exclude from what gets monitored
- The file extensions to include or exclude from what gets monitored
- Whether to do file extension checks on directory objects

There are special considerations for the scope for a cluster FPolicy policy. The cluster FPolicy policy is a policy that the cluster administrator creates for the admin SVM. If the cluster administrator also creates the scope for that cluster FPolicy policy, the SVM administrator cannot create a scope for that same policy. However, if the cluster administrator does not create a scope for the cluster FPolicy policy, then any SVM administrator can create the scope for that cluster policy. If the SVM administrator creates a scope for that cluster FPolicy policy, the cluster administrator cannot subsequently create a cluster scope for that same cluster policy. This is because the cluster administrator cannot override the scope for the same cluster policy.

== What the scope rules of precedence are

The following rules of precedence apply to scope configurations:

- When a share is included in the `-shares-to-include` parameter and the parent volume of the share is included in the `-volumes-to-exclude` parameter, `-volumes-to-exclude` has precedence over `-shares-to-include`.
- When an export policy is included in the `-export-policies-to-include` parameter and the parent volume of the export policy is included in the `-volumes-to-exclude` parameter, `-volumes-to-exclude` has precedence over `-export-policies-to-include`.
- An administrator can specify both `-file-extensions-to-include` and `-file-extensions-to-exclude` lists.

The `-file-extensions-to-exclude` parameter is checked before the `-file-extensions-to-include` parameter is checked.

== What the FPolicy scope configuration contains

You can use the following list of available FPolicy scope configuration parameters to help you plan your configuration:

When configuring what shares, export policies, volumes, and file extensions to include or exclude from the scope, the include and exclude parameters can contain regular expressions and can include metacharacters such as "?" and "*".

Type of information	Option
SVM Specifies the SVM name on which you want to create an FPolicy scope. Each FPolicy configuration is defined within a single SVM. The external engine, policy event, policy scope, and policy that combine together to create an FPolicy policy configuration must all be associated with the same SVM.	<code>-vserver vserver_name</code>
Policy name Specifies the name of the FPolicy policy to which you want to attach the scope. The FPolicy policy must already exist.	<code>-policy-name policy_name</code>
Shares to include Specifies a comma-delimited list of shares to monitor for the FPolicy policy to which the scope is applied.	<code>-shares-to-include share_name, ...</code>
Shares to exclude Specifies a comma-delimited list of shares to exclude from monitoring for the FPolicy policy to which the scope is applied.	<code>-shares-to-exclude share_name, ...</code>
Volumes to include Specifies a comma-delimited list of volumes to monitor for the FPolicy policy to which the scope is applied.	<code>-volumes-to-include volume_name, ...</code>
Volumes to exclude Specifies a comma-delimited list of volumes to exclude from monitoring for the FPolicy policy to which the scope is applied.	<code>-volumes-to-exclude volume_name, ...</code>
Export policies to include Specifies a comma-delimited list of export policies to monitor for the FPolicy policy to which the scope is applied.	<code>-export-policies-to -include export_policy_name, ...</code>
Export policies to exclude Specifies a comma-delimited list of export policies to exclude from monitoring for the FPolicy policy to which the scope is applied.	<code>-export-policies-to -exclude export_policy_name, ...</code>

<i>File extensions to include</i>	Specifies a comma-delimited list of file extensions to monitor for the FPolicy policy to which the scope is applied.	-file-extensions-to -include file_extensions, ...
<i>File extension to exclude</i>	Specifies a comma-delimited list of file extensions to exclude from monitoring for the FPolicy policy to which the scope is applied.	-file-extensions-to -exclude file_extensions, ...
<i>Is file extension check on directory enabled ?</i>	Specifies whether the file name extension checks apply to directory objects as well. If this parameter is set to <code>true</code> , the directory objects are subjected to the same extension checks as regular files. If this parameter is set to <code>false</code> , the directory names are not matched for extensions and notifications are sent for directories even if their name extensions do not match. If the FPolicy policy to which the scope is assigned is configured to use the native engine, this parameter must be set to <code>true</code> .	-is-file-extension -check-on-directories -enabled {true false }

= Complete the FPolicy scope worksheet

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can use this worksheet to record the values that you need during the FPolicy scope configuration process. If a parameter value is required, you need to determine what value to use for those parameters before you configure the FPolicy scope.

You should record whether you want to include each parameter setting in the FPolicy scope configuration and then record the value for the parameters that you want to include.

Type of information	Required	Include	Your values
Storage virtual machine (SVM) name	Yes	Yes	
Policy name	Yes	Yes	
Shares to include	No		
Shares to exclude	No		
Volumes to include	No		
Volumes to exclude	No		

Export policies to include	No		
Export policies to exclude	No		
File extensions to include	No		
File extension to exclude	No		
Is file extension check on directory enabled?	No		

= Create the FPolicy configuration

= Create the FPolicy external engine

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You must create an external engine to start creating an FPolicy configuration. The external engine defines how FPolicy makes and manages connections to external FPolicy servers. If your configuration uses the internal ONTAP engine (the native external engine) for simple file blocking, you do not need to configure a separate FPolicy external engine and do not need to perform this step.

What you'll need

The external engine worksheet should be completed.

About this task

If the external engine is used in a MetroCluster configuration, you should specify the IP addresses of the FPolicy servers at the source site as primary servers. The IP addresses of the FPolicy servers at the destination site should be specified as secondary servers.

Steps

1. Create the FPolicy external engine by using the `vserver fpolicy policy external-engine create` command.

The following command creates an external engine on storage virtual machine (SVM) `vs1.example.com`. No authentication is required for external communications with the FPolicy server.

```
vserver fpolicy policy external-engine create -vserver-name vs1.example.com
-engine-name engine1 -primary-servers 10.1.1.2,10.1.1.3 -port 6789 -ssl
-option no-auth
```

2. Verify the FPolicy external engine configuration by using the `vserver fpolicy policy external-engine show` command.

The following command display information about all external engines configured on SVM `vs1.example.com`:

```
vserver fpolicy policy external-engine show -vserver vs1.example.com
```

		Primary	Secondary	
Vserver	Engine	Servers	Servers	Port
vs1.example.com	engine1	10.1.1.2, 10.1.1.3	-	6789

The following command displays detailed information about the external engine named “engine1” on SVM vs1.example.com:

```
vserver fpolicy policy external-engine show -vserver vs1.example.com  
-engine-name engine1
```

```
Vserver: vs1.example.com  
Engine: engine1  
Primary FPolicy Servers: 10.1.1.2, 10.1.1.3  
Port Number of FPolicy Service: 6789  
Secondary FPolicy Servers: -  
External Engine Type: synchronous  
SSL Option for External Communication: no-auth  
FQDN or Custom Common Name: -  
Serial Number of Certificate: -  
Certificate Authority: -
```

= Create the FPolicy event

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

As part of creating an FPolicy policy configuration, you need to create an FPolicy event. You associate the event with the FPolicy policy when it is created. An event defines which protocol to monitor and which file access events to monitor and filter.

Before you begin

You should complete the FPolicy event worksheet.

Steps

1. Create the FPolicy event by using the vserver fpolicy policy event create command.

```
vserver fpolicy policy event create -vserver-name vs1.example.com -event  
-name event1 -protocol cifs -file-operations open,close,read,write
```

- Verify the FPolicy event configuration by using the vserver fpolicy policy event show command.

```
vserver fpolicy policy event show -vserver vs1.example.com
```

Event	File	Is
Volume	Name	Protocols Operations Filters
Vserver		
Operation		
-----	-----	-----
-----	-----	-----
vs1.example.com	event1	cifs open, close, - read, write
		false

= Create the FPolicy policy
:icons: font
:relative_path: ./has-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

When you create the FPolicy policy, you associate an external engine and one or more events to the policy. The policy also specifies whether mandatory screening is required, whether the FPolicy servers have privileged access to data on the storage virtual machine (SVM), and whether passthrough-read for offline files is enabled.

What you'll need

- The FPolicy policy worksheet should be completed.
- If you plan on configuring the policy to use FPolicy servers, the external engine must exist.
- At least one FPolicy event that you plan on associating with the FPolicy policy must exist.
- If you want to configure privileged data access, a SMB server must exist on the SVM.

Steps

- Create the FPolicy policy:

```
vserver fpolicy policy create -vserver-name vserver_name -policy-name
policy_name -engine engine_name -events event_name,... [-is-mandatory
{true|false}] [-allow-privileged-access {yes|no}] [-privileged-user-name
domain\user_name] [-is-passthrough-read-enabled {true|false}]
```

- You can add one or more events to the FPolicy policy.
- By default, mandatory screening is enabled.
- If you want to allow privileged access by setting the -allow-privileged-access parameter to yes, you must also configure a privileged user name for privileged access.
- If you want to configure passthrough-read by setting the -is-passthrough-read-enabled parameter to true, you must also configure privileged data access.

The following command creates a policy named "policy1" that has the event named "event1" and

the external engine named “engine1” associated with it. This policy uses default values in the policy configuration:

```
vserver fpolicy policy create -vserver vs1.example.com -policy-name  
policy1 -events event1 -engine engine1
```

The following command creates a policy named “policy2” that has the event named “event2” and the external engine named “engine2” associated with it. This policy is configured to use privileged access using the specified user name. Passthrough-read is enabled:

```
vserver fpolicy policy create -vserver vs1.example.com -policy-name  
policy2 -events event2 -engine engine2 -allow-privileged-access yes  
-privileged-user-name example\archive_acct -is-passthrough-read-enabled  
true
```

The following command creates a policy named “native1” that has the event named “event3” associated with it. This policy uses the native engine and uses default values in the policy configuration:

```
vserver fpolicy policy create -vserver vs1.example.com -policy-name  
native1 -events event3 -engine native
```

2. Verify the FPolicy policy configuration by using the `vserver fpolicy policy show` command.

The following command displays information about the three configured FPolicy policies, including the following information:

- The SVM associated with the policy
- The external engine associated with the policy
- The events associated with the policy
- Whether mandatory screening is required
- Whether privileged access is required

```
vserver fpolicy policy show
```

Vserver Privileged	Policy Name	Events	Engine	Is Mandatory	Access
vs1.example.com	policy1	event1	engine1	true	no
vs1.example.com	policy2	event2	engine2	true	yes
vs1.example.com	native1	event3	native	true	no

= Create the FPolicy scope

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

After creating the FPolicy policy, you need to create an FPolicy scope. When creating the scope, you associate the scope with an FPolicy policy. A scope defines the

boundaries on which the FPolicy policy applies. Scopes can include or exclude files based on shares, export policies, volumes, and file extensions.

What you'll need

The FPolicy scope worksheet must be completed. The FPolicy policy must exist with an associated external engine (if the policy is configured to use external FPolicy servers) and must have at least one associated FPolicy event.

Steps

1. Create the FPolicy scope by using the vserver fpolicy policy scope create command.

```
vserver fpolicy policy scope create -vserver-name vs1.example.com -policy  
-name policy1 -volumes-to-include datavol1,datavol2
```

2. Verify the FPolicy scope configuration by using the vserver fpolicy policy scope show command.

```
vserver fpolicy policy scope show -vserver vs1.example.com -instance
```

```
Vserver: vs1.example.com  
Policy: policy1  
Shares to Include: -  
Shares to Exclude: -  
Volumes to Include: datavol1, datavol2  
Volumes to Exclude: -  
Export Policies to Include: -  
Export Policies to Exclude: -  
File Extensions to Include: -  
File Extensions to Exclude: -
```

= Enable the FPolicy policy

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

After you are through configuring an FPolicy policy configuration, you enable the FPolicy policy. Enabling the policy sets its priority and starts file access monitoring for the policy.

What you'll need

The FPolicy policy must exist with an associated external engine (if the policy is configured to use external FPolicy servers) and must have at least one associated FPolicy event. The FPolicy policy scope must exist and must be assigned to the FPolicy policy.

About this task

The priority is used when multiple policies are enabled on the storage virtual machine (SVM) and more than one policy has subscribed to the same file access event. Policies that use the native engine configuration have a higher priority than policies for any other engine, regardless of the sequence number

assigned to them when enabling the policy.

A policy cannot be enabled on the admin SVM.

Steps

1. Enable the FPolicy policy by using the `vserver fpolicy enable` command.

```
vserver fpolicy enable -vserver-name vs1.example.com -policy-name policy1  
-sequence-number 1
```

2. Verify that the FPolicy policy is enabled by using the `vserver fpolicy show` command.

```
vserver fpolicy show -vserver vs1.example.com
```

Vserver	Policy Name	Sequence Number	Status	Engine
vs1.example.com	policy1	1	on	engine1

= Modify FPolicy configurations

= Commands for modifying FPolicy configurations

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../../media/

You can modify FPolicy configurations by modifying the elements that make up the configuration. You can modify external engines, FPolicy events, FPolicy scopes, and FPolicy policies. You can also enable or disable FPolicy policies. When you disable the FPolicy policy, file monitoring is discontinued for that policy.

It is recommended to disable the FPolicy policy before modifying the configuration.

If you want to modify...	Use this command...
External engines	<code>vserver fpolicy policy external-engine modify</code>
Events	<code>vserver fpolicy policy event modify</code>
Scopes	<code>vserver fpolicy policy scope modify</code>
Policies	<code>vserver fpolicy policy modify</code>

See the man pages for the commands for more information.

= Enable or disable FPolicy policies

:icons: font

```
:relative_path: ./nas-audit/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/
```

You can enable FPolicy policies after the configuration is complete. Enabling the policy sets its priority and starts file access monitoring for the policy. You can disable FPolicy policies if you want to stop file access monitoring for the policy.

What you'll need

Before enabling FPolicy policies, the FPolicy configuration must be completed.

About this task

- The priority is used when multiple policies are enabled on the storage virtual machine (SVM) and more than one policy has subscribed to the same file access event.
- Policies that use the native engine configuration have a higher priority than policies for any other engine, regardless of the sequence number assigned to them when enabling the policy.
- If you want to change the priority of an FPolicy policy, you must disable the policy and then reenable it using the new sequence number.

Step

1. Perform the appropriate action:

If you want to...	Enter the following command...
Enable an FPolicy policy	vserver fpolicy enable -vserver-name vserver_name -policy-name policy_name -sequence -number integer
Disable an FPolicy policy	vserver fpolicy disable -vserver-name vserver_name -policy-name policy_name

= Display information about FPolicy configurations

= How the show commands work

:icons: font

```
:relative_path: ./nas-audit/
```

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/./media/
```

It is helpful when displaying information about the FPolicy configuration to understand how the show commands work.

A show command without additional parameters displays information in a summary form. Additionally, every show command has the same two mutually exclusive optional parameters, -instance and -fields.

When you use the -instance parameter with a show command, the command output displays detailed information in a list format. In some cases, the detailed output can be lengthy and include more information than you need. You can use the -fields fieldname[, fieldname...] parameter to customize the output so that it displays information only for the fields you specify. You can identify which fields that you can specify by entering ? after the -fields parameter.

The output of a `show` command with the `-fields` parameter might display other relevant and necessary fields related to the requested fields.

Every `show` command has one or more optional parameters that filter that output and enable you to narrow the scope of information displayed in command output. You can identify which optional parameters are available for a command by entering `? after the show command.`

The `show` command supports UNIX-style patterns and wildcards to enable you to match multiple values in command-parameters arguments. For example, you can use the wildcard operator (*), the NOT operator (!), the OR operator (|), the range operator (integer...integer), the less-than operator (<), the greater-than operator (>), the less-than or equal to operator (<=), and the greater-than or equal to operator (>=) when specifying values.

For more information about using UNIX-style patterns and wildcards, see the "Using the ONTAP command-line interface" section of the *System Administration Guide for SVM Administrators*.

= Commands for displaying information about FPolicy configurations

You use the `fpolicy show` commands to display information about the FPolicy configuration, including information about FPolicy external engines, events, scopes, and policies.

If you want to display information about FPolicy...	Use this command...
External engines	<code>vserver fpolicy policy external-engine show</code>
Events	<code>vserver fpolicy policy event show</code>
Scopes	<code>vserver fpolicy policy scope show</code>
Policies	<code>vserver fpolicy policy show</code>

See the man pages for the commands for more information.

= Display information about FPolicy policy status

You can display information about the status for FPolicy policies to determine whether a policy is enabled, what external engine it is configured to use, what the sequence number is for the policy, and to which storage virtual machine (SVM) the FPolicy policy is associated.

About this task

If you do not specify any parameters, the command displays the following information:

- SVM name
- Policy name
- Policy sequence number

- Policy status

In addition to displaying information about policy status for FPolicy policies configured on the cluster or a specific SVM, you can use command parameters to filter the command's output by other criteria.

You can specify the `-instance` parameter to display detailed information about listed policies. Alternatively, you can use the `-fields` parameter to display only the indicated fields in the command output, or `-fields ?` to determine what fields you can use.

Step

1. Display filtered information about FPolicy policy status by using the appropriate command:

If you want to display status information about policies...	Enter the command...
On the cluster	<code>vserver fpolicy show</code>
That have the specified status	<code>vserver fpolicy show -status {on off}</code>
On a specified SVM	<code>vserver fpolicy show -vserver vserver_name</code>
With the specified policy name	<code>vserver fpolicy show -policy-name policy_name</code>
That use the specified external engine	<code>vserver fpolicy show -engine engine_name</code>

Example

The following example displays the information about FPolicy policies on the cluster:

cluster1::> vserver fpolicy show					
Sequence					
Vserver	Policy Name	Number	Status	Engine	
FPolicy	cserver_policy	-	off	eng1	
vs1.example.com	v1p1	-	off	eng2	
vs1.example.com	v1p2	-	off	native	
vs1.example.com	v1p3	-	off	native	
vs1.example.com	cserver_policy	-	off	eng1	
vs2.example.com	v1p1	3	on	native	
vs2.example.com	v1p2	1	on	eng3	
vs2.example.com	cserver_policy	2	on	eng1	

= Display information about enabled FPolicy policies

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./nas-audit/..media/

You can display information about enabled FPolicy policies to determine what FPolicy external engine it is configured to use, what the priority is for the policy, and to which storage virtual machine (SVM) the FPolicy policy is associated.

About this task

If you do not specify any parameters, the command displays the following information:

- SVM name
- Policy name
- Policy priority

You can use command parameters to filter the command's output by specified criteria.

Step

1. Display information about enabled FPolicy policies by using the appropriate command:

If you want to display information about enabled policies...	Enter the command...
On the cluster	vserver fpolicy show-enabled
On a specified SVM	vserver fpolicy show-enabled -vserver vserver_name
With the specified policy name	vserver fpolicy show-enabled -policy-name policy_name
With the specified sequence number	vserver fpolicy show-enabled -priority integer

Example

The following example displays the information about enabled FPolicy policies on the cluster:

```
cluster1::> vserver fpolicy show-enabled
Vserver          Policy Name          Priority
-----
vs1.example.com    pol_native        native
vs1.example.com    pol_native2       native
vs1.example.com    pol1             2
vs1.example.com    pol2             4
```

= Manage FPolicy server connections

= Connect to external FPolicy servers

```
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./nas-audit/..media/
```

To enable file processing, you might need to manually connect to an external FPolicy server if the connection has previously been terminated. A connection is terminated after the server timeout is reached or due to some error. Alternatively, the administrator might manually terminate a connection.

About this task

If a fatal error occurs, the connection to the FPolicy server can be terminated. After resolving the issue that caused the fatal error, you must manually reconnect to the FPolicy server.

Steps

1. Connect to the external FPolicy server by using the `vserver fpolicy engine-connect` command.
For more information about the command, see the man pages.
2. Verify that the external FPolicy server is connected by using the `vserver fpolicy show-engine` command.
For more information about the command, see the man pages.

= Disconnect from external FPolicy servers

```
:icons: font
:relative_path: ./nas-audit/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./nas-audit/..media/
```

You might need to manually disconnect from an external FPolicy server. This might be desirable if the FPolicy server has issues with notification request processing or if you need to perform maintenance on the FPolicy server.

Steps

1. Disconnect from the external FPolicy server by using the `vserver fpolicy engine-disconnect` command.
For more information about the command, see the man pages.
2. Verify that the external FPolicy server is disconnected by using the `vserver fpolicy show-engine` command.
For more information about the command, see the man pages.

= Display information about connections to external FPolicy servers

You can display status information about connections to external FPolicy servers (FPolicy servers) for the cluster or for a specified storage virtual machine (SVM). This information can help you determine which FPolicy servers are connected.

About this task

If you do not specify any parameters, the command displays the following information:

- SVM name
- Node name
- FPolicy policy name
- FPolicy server IP address
- FPolicy server status
- FPolicy server type

In addition to displaying information about FPolicy connections on the cluster or a specific SVM, you can use command parameters to filter the command's output by other criteria.

You can specify the `-instance` parameter to display detailed information about listed policies. Alternatively, you can use the `-fields` parameter to display only the indicated fields in the command output. You can enter `?` after the `-fields` parameter to find out which fields you can use.

Step

1. Display filtered information about connection status between the node and the FPolicy server by using the appropriate command:

If you want to display connection status information about FPolicy servers...	Enter...
That you specify	<code>vserver fpolicy show-engine -server IP_address</code>
For a specified SVM	<code>vserver fpolicy show-engine -vserver vserver_name</code>
That are attached with a specified policy	<code>vserver fpolicy show-engine -policy-name policy_name</code>
With the server status that you specify	<code>vserver fpolicy show-engine -server-status status</code> The server status can be one of the following: <ul style="list-style-type: none">• connected• disconnected• connecting• disconnecting

With the specified type	<pre>vserver fpolicy show-engine -server-type type</pre> <p>The FPolicy server type can be one of the following:</p> <ul style="list-style-type: none"> • primary • secondary
That were disconnected with the specified reason	<pre>vserver fpolicy show-engine -disconnect-reason text</pre> <p>Disconnect can be due to multiple reasons. The following are common reasons for disconnect:</p> <ul style="list-style-type: none"> • Disconnect command received from CLI. • Error encountered while parsing notification response from FPolicy server. • FPolicy Handshake failed. • SSL handshake failed. • TCP Connection to FPolicy server failed. • The screen response message received from the FPolicy server is not valid.

Example

This example displays information about external engine connections to FPolicy servers on SVM vs1.example.com:

```
cluster1::> vserver fpolicy show-engine -vserver vs1.example.com
FPolicy
Server-
Server-
Vserver      Policy     Node       Server      status      type
-----  -----  -----  -----  -----
-----  -----
vs1.example.com policy1    node1      10.1.1.2    connected
primary
vs1.example.com policy1    node1      10.1.1.3    disconnected
primary
vs1.example.com policy1    node2      10.1.1.2    connected
primary
vs1.example.com policy1    node2      10.1.1.3    disconnected
primary
```

This example displays information only about connected FPolicy servers:

```

cluster1::> vserver fpolicy show-engine -fields server -server-status
connected
node      vserver          policy-name server
-----
node1    vs1.example.com  policy1     10.1.1.2
node2    vs1.example.com  policy1     10.1.1.2

```

= Display information about the FPolicy passthrough-read connection status

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You can display information about FPolicy passthrough-read connection status to external FPolicy servers (FPolicy servers) for the cluster or for a specified storage virtual machine (SVM). This information can help you determine which FPolicy servers have passthrough-read data connections and for which FPolicy servers the passthrough-read connection is disconnected.

About this task

If you do not specify any parameter, the command displays the following information:

- SVM name
- FPolicy policy name
- Node name
- FPolicy server IP address
- FPolicy passthrough-read connection status

In addition to displaying information about FPolicy connections on the cluster or a specific SVM, you can use command parameters to filter the command's output by other criteria.

You can specify the `-instance` parameter to display detailed information about listed policies. Alternatively, you can use the `-fields` parameter to display only the indicated fields in the command output. You can enter `?` after the `-fields` parameter to find out which fields you can use.

Step

1. Display filtered information about connection status between the node and the FPolicy server by using the appropriate command:

If you want to display connection status information about...	Enter the command...
FPolicy passthrough-read connection status for the cluster	<code>vserver fpolicy show-passthrough-read-connection</code>

FPolicy passthrough-read connection status for a specified SVM	vserver fpolicy show-passthrough-read-connection -vserver vserver_name
FPolicy passthrough-read connection status for a specified policy	vserver fpolicy show-passthrough-read-connection -policy-name policy_name
Detailed FPolicy passthrough-read connection status for a specified policy	vserver fpolicy show-passthrough-read-connection -policy-name policy_name -instance
FPolicy passthrough-read connection status for the status that you specify	vserver fpolicy show-passthrough-read-connection -policy-name policy_name -server -status status The server status can be one of the following: <ul style="list-style-type: none"> • connected • disconnected

Example

The following command displays information about passthrough-read connections from all FPolicy servers on the cluster:

```
cluster1::> vserver fpolicy show-passthrough-read-connection
          FPolicy           Server
Vserver      Policy Name   Node      Server      Status
-----  -----
-----  -----
vs2.example.com  pol_cifs_2    FPolicy-01  2.2.2.2
disconnected
vs1.example.com  pol_cifs_1    FPolicy-01  1.1.1.1           connected
```

The following command displays detailed information about passthrough-read connections from FPolicy servers configured in the “pol_cifs_1” policy:

```

cluster1::> vserver fpolicy show-passthrough-read-connection -policy
-name pol_cifs_1 -instance

                           Node: FPolicy-01
                           Vserver: vs1.example.com
                           Policy: pol_cifs_1
                           Server: 1.1.1.1
Session ID of the Control Channel: 8cef052e-2502-11e3-
88d4-123478563412
                           Server Status: connected
Time Passthrough Read Channel was Connected: 9/24/2013 10:17:45
Time Passthrough Read Channel was Disconnected: -
Reason for Passthrough Read Channel Disconnection: none

```

= Use security tracing to verify or troubleshoot file and directory access

= How security traces work

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./nas-audit../media/

You can add permission tracing filters to instruct ONTAP to log information about why the SMB and NFS servers on a storage virtual machine (SVM) allows or denies a client or user's request to perform an operation. This can be useful when you want to verify that your file access security scheme is appropriate or when you want to troubleshoot file access issues.

Security traces allow you to configure a filter that detects client operations over SMB and NFS on the SVM, and trace all access checks matching that filter. You can then view the trace results, which provides a convenient summary of the reason that access was allowed or denied.

When you want to verify the security settings for SMB or NFS access on files and folders on your SVM or if you are faced with an access problem, you can quickly add a filter to turn on permission tracing.

The following list outlines important facts about how security traces works:

- ONTAP applies security traces at the SVM level.
- Each incoming request is screened to see if it matches filtering criteria of any enabled security traces.
- Traces are performed for both file and folder access requests.
- Traces can filter based on the following criteria:
 - Client IP
 - SMB or NFS path
 - Windows name
 - UNIX name
- Requests are screened for *Allowed* and *Denied* access response results.

- Each request matching filtering criteria of enabled traces is recorded in the trace results log.
- The storage administrator can configure a timeout on a filter to automatically disable it.
- If a request matches multiple filters, the results from the filter with the highest index number is recorded.
- The storage administrator can print results from the trace results log to determine why an access request was allowed or denied.

= Types of access checks security traces monitor

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

Access checks for a file or folder are done based on multiple criteria. Security traces monitor operations on all these criteria.

The types of access checks that security traces monitor include the following:

- Volume and qtree security style
- Effective security of the file system containing the files and folders on which operations are requested
- User mapping
- Share-level permissions
- Export-level permissions
- File-level permissions
- Storage-Level Access Guard security

= Considerations when creating security traces

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You should keep several considerations in mind when you create security traces on storage virtual machines (SVMs). For example, you need to know on which protocols you can create a trace, which security-styles are supported, and what the maximum number of active traces is.

- You can only create security traces on SVMs.
- Each security trace filter entry is SVM specific.

You must specify the SVM on which you want to run the trace.

- You can add permission tracing filters for SMB and NFS requests.
- You must set up the SMB or NFS server on the SVM on which you want to create trace filters.
- You can create security traces for files and folders residing on NTFS, UNIX, and mixed security-style volumes and qtrees.
- You can add a maximum of 10 permission tracing filters per SVM.
- You must specify a filter index number when creating or modifying a filter.

Filters are considered in order of the index number. The criteria in a filter with a higher index number is considered before the criteria with a lower index number. If the request being traced matches criteria in multiple enabled filters, only the filter with the highest index number is triggered.

- After you have created and enabled a security trace filter, you must perform some file or folder requests on a client system to generate activity that the trace filter can capture and log in the trace results log.
- You should add permission tracing filters for file access verification or troubleshooting purposes only.

Adding permission tracing filters has a minor effect on controller performance.

When you are done with verification or troubleshooting activity, you should disable or remove all permission tracing filters. Furthermore, the filtering criteria you select should be as specific as possible so that ONTAP does not send a large number of trace results to the log.

= Perform security traces

= Perform security traces overview

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

Performing a security trace involves creating a security trace filter, verifying the filter criteria, generating access requests on an SMB or NFS client that match filter criteria, and viewing the results.

After you are finished using a security filter to capture trace information, you can modify the filter and reuse it, or disable it if you no longer need it. After viewing and analyzing the filter trace results, you can then delete them if they are no longer needed.

= Create security trace filters

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You can create security trace filters that detect SMB and NFS client operations on storage virtual machines (SVMs) and trace all access checks matching the filter. You can use the results from security traces to validate your configuration or to troubleshoot access issues.

About this task

There are two required parameters for the vserver security trace filter create command:

Required parameters	Description
-vserver vserver_name	<p>SVM name</p> <p>The name of the SVM that contains the files or folders on which you want to apply the security trace filter.</p>

<code>-index index_number</code>	<p><i>Filter index number</i></p> <p>The index number you want to apply to the filter. You are limited to a maximum of 10 trace filters per SVM. The allowed values for this parameter are 1 through 10.</p>
----------------------------------	--

A number of optional filter parameters enable you to customize the security trace filter so that you can narrow down the results produced by the security trace:

Filter parameter	Description
<code>-client-ip IP_Address</code>	This filter specifies the IP address from which the user is accessing the SVM.
<code>-path path</code>	<p>This filter specifies the path on which to apply the permission trace filter. The value for <code>-path</code> can use either of the following formats:</p> <ul style="list-style-type: none"> • The complete path, starting from the root of the share or export • A partial path, relative to the root of the share <p>You must use NFS style directory UNIX-style directory separators in the path value.</p>
<code>-windows-name</code> <code>win_user_name</code> or <code>-unix-name``unix_user_name</code>	<p>You can specify either the Windows user name or UNIX user name whose access requests you want to trace. The user name variable is case insensitive. You cannot specify both a Windows user name and a UNIX user name in the same filter.</p> <p> Even though you can trace SMB and NFS access events, the mapped UNIX user and the mapped UNIX users' groups might be used when performing access checks on mixed or UNIX security-style data.</p>
<code>-trace-allow {yes no}</code>	Tracing for deny events is always enabled for a security trace filter. You can optionally trace allow events. To trace allow events, you set this parameter to yes.
<code>-enabled {enabled disabled}</code>	You can enable or disable the security trace filter. By default, the security trace filter is enabled.
<code>-time-enabled integer</code>	You can specify a timeout for the filter, after which it is disabled.

Steps

1. Create a security trace filter:

```
vserver security trace filter create -vserver vserver_name -index
index_numberfilter_parameters
```

`filter_parameters` is a list of optional filter parameters.

For more information, see the man pages for the command.

2. Verify the security trace filter entry:

```
vserver security trace filter show -vserver vserver_name -index  
index_number
```

Examples

The following command creates a security trace filter for any user accessing a file with a share path \\server\share1\dir1\dir2\file.txt from the IP address 10.10.10.7. The filter uses a complete path for the -path option. The client's IP address used to access data is 10.10.10.7. The filter times out after 30 minutes:

```
cluster1::> vserver security trace filter create -vserver vs1 -index 1  
-path /dir1/dir2/file.txt -time-enabled 30 -client-ip 10.10.10.7  
cluster1::> vserver security trace filter show -index 1  
Vserver Index Client-IP Path Trace-Allow  
Windows-Name  
----- ----- ----- -----  
-----  
vs1 1 10.10.10.7 /dir1/dir2/file.txt no -
```

The following command creates a security trace filter using a relative path for the -path option. The filter traces access for a Windows user named "joe". Joe is accessing a file with a share path \\server\share1\dir1\dir2\file.txt. The filter traces allow and deny events:

```
cluster1::> vserver security trace filter create -vserver vs1 -index 2  
-path /dir1/dir2/file.txt -trace-allow yes -windows-name mydomain\joe  
  
cluster1::> vserver security trace filter show -vserver vs1 -index 2  
Vserver: vs1  
Filter Index: 2  
Client IP Address to Match: -  
Path: /dir1/dir2/file.txt  
Windows User Name: mydomain\joe  
UNIX User Name: -  
Trace Allow Events: yes  
Filter Enabled: enabled  
Minutes Filter is Enabled: 60
```

= Display information about security trace filters

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./nas-audit/..media/

You can display information about security trace filters configured on your storage

virtual machine (SVM). This enables you to see which types of access events each filter traces.

Step

1. Display information about security trace filter entries by using the vserver security trace filter show command.

For more information about using this command, see the man pages.

Examples

The following command displays information about all security trace filters on SVM vs1:

```
cluster1::> vserver security trace filter show -vserver vs1
Vserver  Index  Client-IP          Path          Trace-Allow
Windows-Name
-----
-----
vs1      1      -                /dir1/dir2/file.txt    yes      -
vs1      2      -                /dir3/dir4/           no
mydomain\joe
```

= Display security trace results

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./nas-audit/..media/

You can display the security trace results generated for file operations that match security trace filters. You can use the results to validate your file access security configuration or to troubleshoot SMB and NFS file access issues.

What you'll need

An enabled security trace filter must exist and operations must have been performed from an SMB or NFS client that matches the security trace filter to generate security trace results.

About this task

You can display a summary of all security trace results, or you can customize what information is displayed in the output by specifying optional parameters. This can be helpful when the security trace results contain a large number of records.

If you do not specify any of the optional parameters, the following is displayed:

- storage virtual machine (SVM) name
- Node name
- Security trace index number
- Security style
- Path
- Reason

- User name

The user name is displayed depending on how the trace filter is configured:

If the filter is configured...	Then...
With a UNIX user name	The security trace result displays the UNIX user name.
With a Windows user name	The security trace result displays the Windows user name.
Without a user name	The security trace result displays the Windows user name.

You can customize the output by using optional parameters. Some of the optional parameters that you can use to narrow the results returned in the command output include the following:

Optional parameter	Description
-fields field_name, ...	Displays output on the fields you choose. You can use this parameter either alone or in combination with other optional parameters.
-instance	Displays detailed information about security trace events. Use this parameter with other optional parameters to display detailed information about specific filter results.
-node node_name	Displays information only about events on the specified node.
-vserver vserver_name	Displays information only about events on the specified SVM.
-index integer	Displays information about the events that occurred as a result of the filter corresponding to the specified index number.
-client-ip IP_address	Displays information about the events that occurred as a result of file access from the specified client IP address.
-path path	Displays information about the events that occurred as a result of file access to the specified path.
-user-name user_name	Displays information about the events that occurred as a result of file access by the specified Windows or UNIX user.
-security-style security_style	Displays information about the events that occurred on file systems with the specified security style.

See the man page for information about other optional parameters that you can use with the command.

Step

1. Display security trace filter results by using the vserver security trace trace-result show command.

```
vserver security trace trace-result show -user-name domain\user
```

Vserver: vs1			
Node	Index	Filter Details	Reason
node1	3	User:domain\user ACE Security Style:mixed Path:/dir1/dir2/	Access denied by explicit
node1	5	User:domain\user ACE Security Style:unix Path:/dir1/	Access denied by explicit

= Modify security trace filters

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

If you want to change the optional filter parameters used to determine which access events are traced, you can modify existing security trace filters.

About this task

You must identify which security trace filter you want to modify by specifying the storage virtual machine (SVM) name on which the filter is applied and the index number of the filter. You can modify all the optional filter parameters.

Steps

1. Modify a security trace filter:

```
vserver security trace filter modify -vserver vserver_name -index  
index_numberfilter_parameters
```

- vserver_name is the name of the SVM on which you want to apply a security trace filter.
- index_number is the index number that you want to apply to the filter. The allowed values for this parameter are 1 through 10.
- filter_parameters is a list of optional filter parameters.

2. Verify the security trace filter entry:

```
vserver security trace filter show -vserver vserver_name -index  
index_number
```

Example

The following command modifies the security trace filter with the index number 1. The filter traces events for any user accessing a file with a share path \\server\share1\dir1\dir2\file.txt from any IP address. The filter uses a complete path for the –path option. The filter traces allow and deny events:

```
cluster1::> vserver security trace filter modify -vserver vs1 -index 1  
-path /dir1/dir2/file.txt -trace-allow yes  
  
cluster1::> vserver security trace filter show -vserver vs1 -index 1  
Vserver: vs1  
Filter Index: 1  
Client IP Address to Match: -  
Path: /dir1/dir2/file.txt  
Windows User Name: -  
UNIX User Name: -  
Trace Allow Events: yes  
Filter Enabled: enabled  
Minutes Filter is Enabled: 60
```

= Delete security trace filters

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

When you no longer need a security trace filter entry, you can delete it. Because you can have a maximum of 10 security trace filters per storage virtual machine (SVM), deleting unneeded filters enables you to create new filters if you have reached the maximum.

About this task

To uniquely identify the security trace filter that you want to delete, you must specify the following:

- The name of the SVM to which the trace filter is applied
- The filter index number of the trace filter

Steps

1. Identify the filter index number of the security trace filter entry you want to delete:

```
vserver security trace filter show -vserver vserver_name  
  
vserver security trace filter show -vserver vs1
```

Vserver	Index	Client-IP	Path	Trace-Allow
Windows-Name				
vs1	1	-	/dir1/dir2/file.txt	yes
vs1	2	-	/dir3/dir4/	no
mydomain\joe				

2. Using the filter index number information from the previous step, delete the filter entry:

```
vserver security trace filter delete -vserver vserver_name -index
index_number
```

```
vserver security trace filter delete -vserver vs1 -index 1
```

3. Verify that the security trace filter entry is deleted:

```
vserver security trace filter show -vserver vserver_name
```

```
vserver security trace filter show -vserver vs1
```

Vserver	Index	Client-IP	Path	Trace-Allow
Windows-Name				
vs1	2	-	/dir3/dir4/	no
mydomain\joe				

= Delete security trace records

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./nas-audit/..media/

After you finish using a filter trace record to verify file access security or to troubleshoot SMB or NFS client access issues, you can delete the security trace record from the security trace log.

About this task

Before you can delete a security trace record, you must know the record's sequence number.

 Each storage virtual machine (SVM) can store a maximum of 128 trace records. If the maximum is reached on the SVM, the oldest trace records are automatically deleted as new ones are added. If you do not want to manually delete trace records on this SVM, you can let ONTAP automatically delete the oldest trace results after the maximum is reached to make room for new results.

Steps

1. Identify the sequence number of the record you want to delete:

```
vserver security trace trace-result show -vserver vserver_name -instance
```

2. Delete the security trace record:

```
vserver security trace trace-result delete -node node_name -vserver  
vserver_name -seqnum integer
```

```
vserver security trace trace-result delete -vserver vs1 -node node1 -seqnum  
999
```

- -node node_name is the name of the cluster node on which the permission tracing event that you want to delete occurred.

This is a required parameter.

- -vserver vserver_name is the name of the SVM on which the permission tracing event that you want to delete occurred.

This is a required parameter.

- -seqnum integer is the sequence number of the log event that you want to delete.

This is a required parameter.

= Delete all security trace records

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

If you do not want to keep any of the existing security trace records, you can delete all of the records on a node with a single command.

Step

1. Delete all security trace records:

```
vserver security trace trace-result delete -node node_name -vserver  
vserver_name *
```

- -node node_name is the name of the cluster node on which the permission tracing event that you want to delete occurred.

- -vserver vserver_name is the name of the storage virtual machine (SVM) on which the permission tracing event that you want to delete occurred.

= Interpret security trace results

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

Security trace results provide the reason that a request was allowed or denied. Output displays the result as a combination of the reason for allowing or denying

access and the location within the access checking pathway where access is either allowed or denied. You can use the results to isolate and identify why actions are or are not allowed.

== Finding information about the lists of result types and filter details

You can find the lists of result types and filter details that can be included in the security trace results in the man pages for the vserver security trace trace-result show command.

Example of output from the Reason field in an Allow result type

The following is an example of the output from the Reason field that appears in the trace results log in an Allow result type:

Access is allowed because SMB implicit permission grants requested access while opening existing file or directory.

Access is allowed because NFS implicit permission grants requested access while opening existing file or directory.

Example of output from the Reason field in an Deny result type

The following is an example of the output from the Reason field that appears in the trace results log in a Deny result type:

Access is denied. The requested permissions are not granted by the ACE while checking for child-delete access on the parent.

Example of output from the Filter details field

The following is an example of the output from the Filter details field in the trace results log, which list the effective security style of the file system containing files and folders that match the filter criteria:

Security Style: MIXED and ACL

= Where to find additional information

:icons: font

:relative_path: ./nas-audit/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./nas-audit/..media/

After you have successfully tested SMB client access, you can perform advanced SMB configuration or add SAN access. After you have successfully tested NFS client access, you can perform advanced NFS configuration or add SAN access. When protocol access is complete, you should protect the root volume of SVM.

== SMB configuration

You can further configure SMB access using the following:

- [SMB management](#)

Describes how to configure and manage file access using the SMB protocol.

- [NetApp Technical Report 4191: Best Practices Guide for Clustered Data ONTAP 8.2 Windows File Services](#)

Provides a brief overview of SMB implementation and other Windows File Services features with recommendations and basic troubleshooting information for ONTAP.

- [NetApp Technical Report 3740: SMB 2 Next-Generation CIFS Protocol in Data ONTAP](#)

Describes SMB 2 features, configuration details, and its implementation in ONTAP.

== NFS configuration

You can further configure NFS access using the following:

- [NFS management](#)

Describes how to configure and manage file access using the NFS protocol.

- [NetApp Technical Report 4067: NFS Best Practice and Implementation Guide](#)

Serves as an NFSv3 and NFSv4 operational guide and provides an overview of ONTAP operating system with a focus on NFSv4.

- [NetApp Technical Report 4668: Name Services Best Practices Guide](#)

Provides a comprehensive list of best practices, limits, recommendations, and considerations when configuring LDAP, NIS, DNS, and local user and group files for authentication purposes.

- [NetApp Technical Report 4616: NFS Kerberos in ONTAP with Microsoft Active Directory](#)

- [NetApp Technical Report 4835: How to Configure LDAP in ONTAP](#)

- [NetApp Technical Report 3580: NFSv4 Enhancements and Best Practices Guide Data ONTAP Implementation](#)

Describes the best practices that should be followed while implementing NFSv4 components on AIX, Linux, or Solaris clients attached to systems running ONTAP.

== Root volume protection

After configuring protocols on the SVM, you should ensure that its root volume is protected:

- [Data protection](#)

Describes how to create a load-sharing mirror to protect the SVM root volume, which is a NetApp best practice for NAS-enabled SVMs. Also describes how to quickly recover from volume failures or losses by promoting the SVM root volume from a load-sharing mirror.

= Manage encryption with System Manager

= Encrypt stored data using software-based encryption
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit./media/

Use volume encryption to ensure that volume data cannot be read if the underlying device is repurposed, returned, misplaced, or stolen. Volume encryption does not require special disks; it works with all HDDs and SSDs.

Volume encryption requires a key manager. You can configure the Onboard Key Manager using System Manager. You can also use an external key manager, but you need to first set it up using the ONTAP CLI.

After the key manager is configured, new volumes are encrypted by default.

Steps

1. Click **Cluster > Settings**.
2. Under **Encryption**, click  to configure the Onboard Key Manager for the first time.
3. To encrypt existing volumes, click **Storage > Volumes**.
4. On the desired volume, click  and then click **Edit**.
5. Select **Enable encryption**.

= Encrypt stored data using self-encrypting drives
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit./media/

Use disk encryption to ensure that all data in a local tier cannot be read if the underlying device is repurposed, returned, misplaced, or stolen. Disk encryption requires special self-encrypting HDDs or SSDs.

Disk encryption requires a key manager. You can configure the onboard key manager using System Manager. You can also use an external key manager, but you need to first set it up using the ONTAP CLI.

If ONTAP detects self-encrypting disks, it prompts you to configure the onboard key manager when you create the local tier.

Steps

1. Under **Encryption**, click  to configure the onboard key manager.
2. If you see a message that disks need to be rekeyed, click , and then click **Rekey Disks**.

= Manage encryption with the CLI

= NetApp Encryption overview with the CLI

```
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/
```

NetApp offers both software- and hardware-based encryption technologies for ensuring that data at rest cannot be read if the storage medium is repurposed, returned, misplaced, or stolen.

- Software-based encryption supports data encryption one volume at a time.
- Hardware-based encryption supports full-disk encryption (FDE) of data as it is written.

You can work with encryption if the following apply:

- You want to use best practices, not explore every available option.
- You want to use the ONTAP command-line interface (CLI), not System Manager or an automated scripting tool.

= Configure NetApp Volume Encryption

= Configure NetApp Volume Encryption overview

```
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/
```

NetApp Volume Encryption (NVE) is a software-based technology for encrypting data at rest one volume at a time. An encryption key accessible only to the storage system ensures that volume data cannot be read if the underlying device is repurposed, returned, misplaced, or stolen.

== Understanding NVE

Both data, including Snapshot copies, and metadata are encrypted. Access to the data is given by a unique XTS-AES-256 key, one per volume. An external key management server or Onboard Key Manager serves keys to nodes:

- The external key management server is a third-party system in your storage environment that serves keys to nodes using the Key Management Interoperability Protocol (KMIP). It is a best practice to configure external key management servers on a different storage system from your data.
- The Onboard Key Manager is a built-in tool that serves keys to nodes from the same storage system as your data.

Beginning with ONTAP 9.7, aggregate and volume encryption is enabled by default if you have a volume encryption (VE) license and use an onboard or external key manager. Whenever an external or onboard key manager is configured there is a change in how the encryption of data at rest is configured for brand new aggregates and brand new volumes. Brand new aggregates will have NetApp Aggregate Encryption (NAE) enabled by default. Brand new volumes that are not part of an NAE aggregate will have NetApp Volume Encryption (NVE) enabled by default. If a data storage virtual machine (SVM) is configured with its own key-manager using multi-tenant key management, then the volume created for that SVM is automatically configured with NVE.

You can enable encryption on a new or existing volume. NVE supports the full range of storage efficiency features, including deduplication and compression.

If you are using SnapLock, you can enable encryption only on new, empty SnapLock volumes. You cannot enable encryption on an existing SnapLock volume.

You can use NVE on any type of aggregate (HDD, SSD, hybrid, array LUN), with any RAID type, and in any supported ONTAP implementation, including ONTAP Select. You can also use NVE with hardware-based encryption to “double encrypt” data on self-encrypting drives.

AFF A220, AFF A800, FAS2720, FAS2750, and later systems store core dumps on their boot device. When NVE is enabled on these systems, the core dump is also encrypted.

== Aggregate-level encryption

Ordinarily, every encrypted volume is assigned a unique key. When the volume is deleted, the key is deleted with it.

Beginning with ONTAP 9.6, you can use *NetApp Aggregate Encryption (NAE)* to assign keys to the containing aggregate for the volumes to be encrypted. When an encrypted volume is deleted, the keys for the aggregate are preserved. The keys are deleted the entire aggregate is deleted.

You must use aggregate-level encryption if you plan to perform inline or background aggregate-level deduplication. Aggregate-level deduplication is otherwise not supported by NVE.

Beginning with ONTAP 9.7, aggregate and volume encryption is enabled by default if you have a volume encryption (VE) license and use an onboard or external key manager.

NVE and NAE volumes can coexist on the same aggregate. Volumes encrypted under aggregate-level encryption are NAE volumes by default. You can override the default when you encrypt the volume.

You can use the `volume move` command to convert an NVE volume to an NAE volume, and vice versa. You can replicate an NAE volume to an NVE volume.

== When to use external key management servers

Although it is less expensive and typically more convenient to use the onboard key manager, you should set up KMIP servers if any of the following are true:

- Your encryption key management solution must comply with Federal Information Processing Standards (FIPS) 140-2 or the OASIS KMIP standard.
- You need a multi-cluster solution, with centralized management of encryption keys.
- Your business requires the added security of storing authentication keys on a system or in a location different from the data.

== Scope of external key management

The scope of external key management determines whether key management servers secure all the SVMs in the cluster or selected SVMs only:

- You can use a *cluster scope* to configure external key management for all the SVMs in the cluster. The cluster administrator has access to every key stored on the servers.
- Beginning with ONTAP 9.6, you can use an *SVM scope* to configure external key management for a named SVM in the cluster. That's best for multitenant environments in which each tenant uses a different SVM (or set of SVMs) to serve data. Only the SVM administrator for a given tenant has access to the keys for that tenant.

- Beginning with ONTAP 9.10.1, you can use [Azure Key Vault](#) and [Google Cloud KMS](#) to protect NVE keys only for data vservers.

You can use both scopes in the same cluster. If key management servers have been configured for an SVM, ONTAP uses only those servers to secure keys. Otherwise, ONTAP secures keys with the key management servers configured for the cluster.

A list of validated external key managers is available in the [NetApp Interoperability Matrix Tool \(IMT\)](#). You can find this list by entering the term "key managers" into the IMT's search feature.

== Support details

The following table shows NVE support details:

Resource or feature	Support details
Platforms	AES-NI offload capability required. See the Hardware Universe (HWU) to verify that NVE and NAE are supported for your platform.
Encryption	<p>Beginning with ONTAP 9.7, newly created aggregates and volumes are encrypted by default when you add a volume encryption (VE) license and have an onboard or external key manager configured. If you need to create an unencrypted aggregate, use the following command:</p> <pre>storage aggregate create -encrypt-with-aggr-key false</pre> <p>If you need to create a plain text volume, use the following command:</p> <pre>volume create -encrypt false</pre> <p>Encryption is not enabled by default when:</p> <ul style="list-style-type: none"> • VE license is not installed. • Key manager is not configured. • Platform or software does not support encryption. • Hardware encryption is enabled.
ONTAP	All ONTAP implementations. Support for ONTAP Cloud is available in ONTAP 9.5 and later.
Devices	HDD, SSD, hybrid, array LUN.
RAID	RAID0, RAID4, RAID-DP, RAID-TEC.
Volumes	Data volumes and existing root volumes. You cannot encrypt data on an SVM root volume or MetroCluster metadata volumes.

Aggregate-level encryption	<p>Beginning with ONTAP 9.6, NVE supports aggregate-level encryption (NAE):</p> <ul style="list-style-type: none"> • You must use aggregate-level encryption if you plan to perform inline or background aggregate-level deduplication. • You cannot rekey an aggregate-level encryption volume. • Secure-purge is not supported on aggregate-level encryption volumes. • In addition to data volumes, NAE supports encryption of SVM root volumes and the MetroCluster metadata volume. NAE does not support encryption of the root volume.
SVM scope	<p>Beginning with ONTAP 9.6, NVE supports SVM scope for external key management only, not for Onboard Key Manager. MetroCluster is supported beginning with ONTAP 9.8.</p>
Storage efficiency	<p>Deduplication, compression, compaction, FlexClone. Clones use the same key as the parent, even after splitting the clone from the parent. You are warned to rekey the split clone.</p>
Replication	<ul style="list-style-type: none"> • For volume replication, the destination volume must have been enabled for encryption. Encryption can be configured for the source and unconfigured for the destination, and vice versa. • For SVM replication, the destination volume is automatically encrypted, unless the destination does not contain a node that supports volume encryption, in which case replication succeeds, but the destination volume is not encrypted. • For MetroCluster configurations, each cluster pulls external key management keys from its configured key servers. OKM keys are replicated to the partner site by the configuration replication service.
Compliance	<p>Beginning with ONTAP 9.2, SnapLock is supported in both Compliance and Enterprise modes, for new volumes only. You cannot enable encryption on an existing SnapLock volume.</p>
FlexGroups	<p>Beginning with ONTAP 9.2, FlexGroups are supported. Destination aggregates must be of the same type as source aggregates, either volume-level or aggregate-level. Beginning with ONTAP 9.5, in-place rekey of FlexGroup volumes is supported.</p>
7-Mode transition	<p>Beginning with 7-Mode Transition Tool 3.3, you can use the 7-Mode Transition Tool CLI to perform copy-based transition to NVE-enabled destination volumes on the clustered system.</p>

= NetApp Volume Encryption workflow

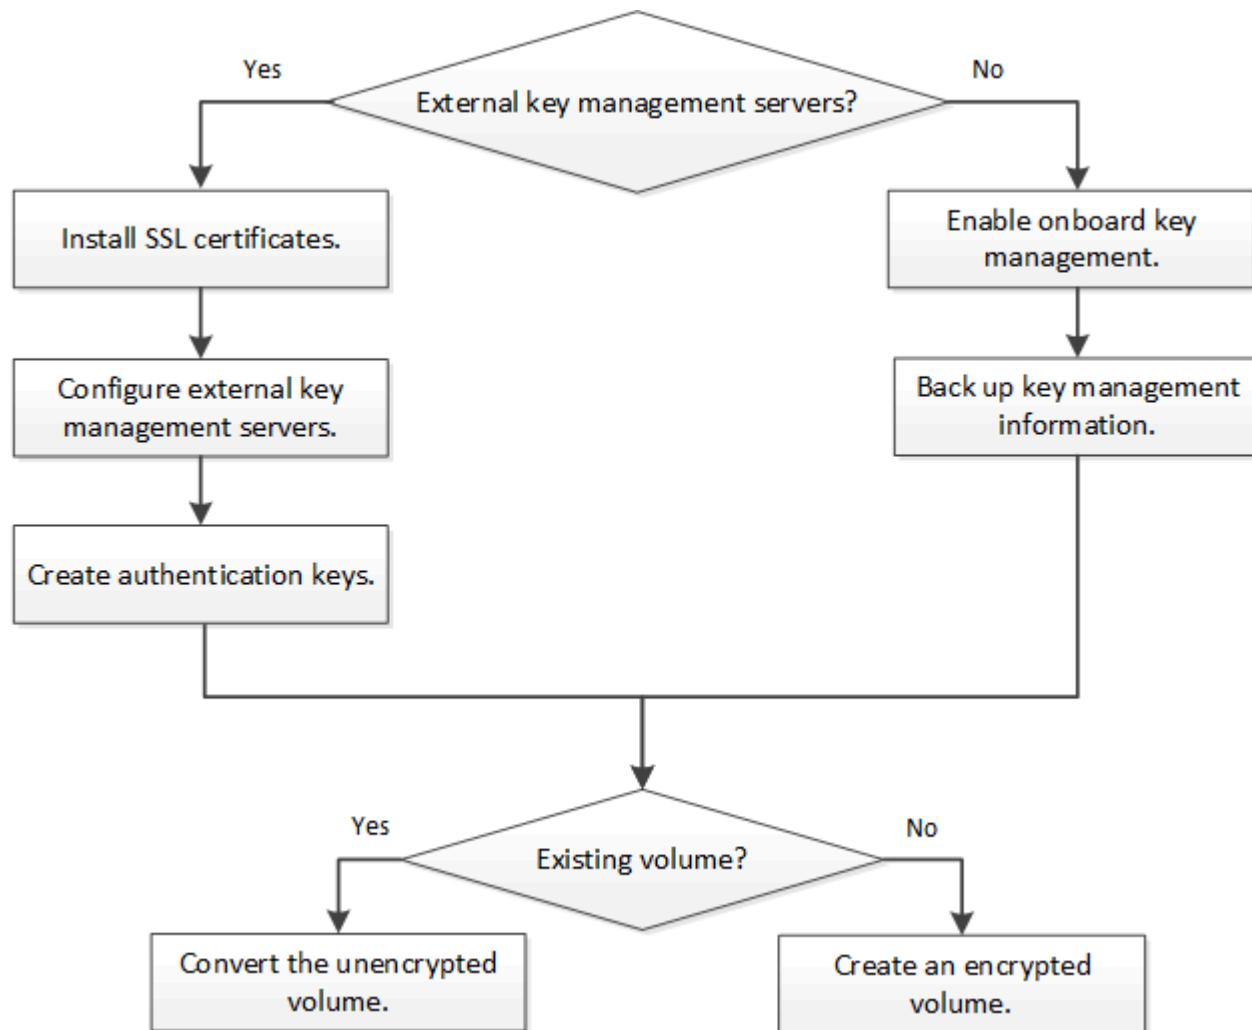

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You must configure key management services before you can enable volume

encryption. You can enable encryption on a new volume or on an existing volume.

You must install the VE license and configure key management services before you can encrypt data with NVE. Before installing the license, you should [determine whether your ONTAP version supports NVE](#).

= Configure NVE

= Determine whether your cluster version supports NVE

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You should determine whether your cluster version supports NVE before you install the license. You can use the `version` command to determine the cluster version.

About this task

The cluster version is the lowest version of ONTAP running on any node in the cluster.

Step

1. Determine whether your cluster version supports NVE:

```
version -v
```

NVE is not supported if the command output displays the text “1Ono-DARE” (for “no Data At Rest Encryption”), or if you are using a platform that is not listed in [Support details](#).

The following command determines whether NVE is supported on cluster1.

```
cluster1::> version -v
NetApp Release 9.1.0: Tue May 10 19:30:23 UTC 2016 <1Ono-DARE>
```

The text “1Ono-DARE” in the command output indicates that NVE is not supported on your cluster version.

= Install the license
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

A VE license entitles you to use the feature on all nodes in the cluster. You must install the license before you can encrypt data with NVE.

What you'll need

You must be a cluster administrator to perform this task.

About this task

You should have received the VE license key from your sales representative.

Steps

1. Install the VE license for a node:

```
system license add -license-code license_key
```

The following command installs the license with the key AAAAAAAAAAAAAAAAAAAAAA.

```
cluster1::> system license add -license-code
AAAAAAAAAAAAAAAAAAAAA
```

2. Verify that the license is installed by displaying all the licenses on the cluster:

```
system license show
```

For complete command syntax, see the man page for the command.

The following command displays all the licenses on cluster1:

```
cluster1::> system license show
```

The VE license package name is “VE”.

= Configure external key management

= Configure external key management overview

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You can use one or more external key management servers to secure the keys that the cluster uses to access encrypted data. An external key management server is a third-party system in your storage environment that serves keys to nodes using the Key Management Interoperability Protocol (KMIP).

For ONTAP 9.1 and earlier versions, node management LIFs must be assigned to ports that are configured with the node management role before you can use the external key manager.

NetApp Volume Encryption (NVE) supports Onboard Key Manager in ONTAP 9.1 and later. In ONTAP 9.3 and later, NVE supports external key management (KMIP) and Onboard Key Manager.

= Install SSL certificates on the cluster

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

The cluster and KMIP server use KMIP SSL certificates to verify each other's identity and establish an SSL connection. Before configuring the SSL connection with the KMIP server, you must install the KMIP client SSL certificates for the cluster, and the SSL public certificate for the root certificate authority (CA) of the KMIP server.

What you'll need

- The time must be synchronized on the server creating the certificates, the KMIP server, and the cluster.
- You must have obtained the public SSL KMIP client certificate for the cluster.
- You must have obtained the private key associated with the SSL KMIP client certificate for the cluster.

The SSL KMIP client certificate must not be password-protected.

- You must have obtained the SSL public certificate for the root certificate authority (CA) of the KMIP server.

You can install the client and server certificates on the KMIP server before or after installing the certificates on the cluster.

About this task

In an HA pair, both nodes must use the same public and private KMIP SSL certificates. If you connect multiple HA pairs to the same KMIP server, all nodes in the HA pairs must use the same public and private KMIP SSL certificates.

Steps

1. Install the SSL KMIP client certificates for the cluster:

```
security certificate install -vserver admin_svm_name -type client
```

You are prompted to enter the SSL KMIP public and private certificates.

```
cluster1::> security certificate install -vserver cluster1 -type client
```

2. Install the SSL public certificate for the root certificate authority (CA) of the KMIP server:

```
security certificate install -vserver admin_svm_name -type server-ca
```

```
cluster1::> security certificate install -vserver cluster1 -type server-ca
```

= Enable external key management in ONTAP 9.6 and later (NVE)

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./nas-audit/..media/

You can use one or more KMIP servers to secure the keys the cluster uses to access encrypted data. Beginning with ONTAP 9.6, you can use one or more KMIP servers to secure the keys a given SVM uses to access encrypted data.

What you'll need

- The KMIP SSL client and server certificates must have been installed.
- You must be a cluster or SVM administrator to perform this task.
- If you want to enable external key management for a MetroCluster environment, MetroCluster must be fully configured before enabling external key management.

About this task

You can connect up to four KMIP servers to a cluster or SVM. A minimum of two servers is recommended for redundancy and disaster recovery.

The scope of external key management determines whether key management servers secure all the SVMs in the cluster or selected SVMs only:

- You can use a *cluster scope* to configure external key management for all the SVMs in the cluster. The cluster administrator has access to every key stored on the servers.
- Beginning with ONTAP 9.6, you can use an *SVM scope* to configure external key management for a data SVM in the cluster. That's best for multitenant environments in which each tenant uses a different SVM (or set of SVMs) to serve data. Only the SVM administrator for a given tenant has access to the keys for that tenant.
- For multitenant environments, install a license for *MT_EK_MGMT* by using the following command:

```
system license add -license-code <MT_EK_MGMT license code>
```

For complete command syntax, see the man page for the command.

You can use both scopes in the same cluster. If key management servers have been configured for an SVM, ONTAP uses only those servers to secure keys. Otherwise, ONTAP secures keys with the key management servers configured for the cluster.

You can configure onboard key management at the cluster scope and external key management at the SVM scope. You can use the `security key-manager key migrate` command to migrate keys from onboard key management at the cluster scope to external key managers at the SVM scope.

Steps

1. Configure key manager connectivity for the cluster:

```
security key-manager external enable -vserver admin_SVM -key-servers  
host_name|IP_address:port,... -client-cert client_certificate -server-ca-cert  
server_CA_certificates
```

The `security key-manager external enable` command replaces the `security key-manager setup` command. If you run the command at the cluster login prompt, `admin_SVM` defaults to the admin SVM of the current cluster. You must be the cluster administrator to configure cluster scope. You can run the `security key-manager external modify` command to change the external key management configuration.

The following command enables external key management for `cluster1` with three external key servers. The first key server is specified using its hostname and port, the second is specified using an IP address and the default port, and the third is specified using an IPv6 address and port:

```
cluster1::> security key-manager external enable -vserver cluster1  
-key-servers  
ks1.local:15696,10.0.0.10,[fd20:8ble:b255:814e:32bd:f35c:832c:5a09]:  
1234 -client-cert AdminVserverClientCert -server-ca-certs  
AdminVserverServerCaCert
```

2. Configure a key manager an SVM:

```
security key-manager external enable -vserver SVM -key-servers  
host_name|IP_address:port,... -client-cert client_certificate -server-ca-cert  
server_CA_certificates
```

If you run the command at the SVM login prompt, `SVM` defaults to the current SVM. You must be a cluster or SVM administrator to configure SVM scope. You can run the `security key-manager external modify` command to change the external key management configuration.

The following command enables external key management for `svm1` with a single key server listening on the default port 5696:

```
svm1::> security key-manager external enable -vserver svm1 -key  
-servers keyserver.svm1.com -client-cert SVM1ClientCert -server-ca  
-certs SVM1ServerCaCert
```

3. Repeat the last step for any additional SVMs.

You can also use the security key-manager external add-servers command to configure additional SVMs. The security key-manager external add-servers command replaces the security key-manager add command. For complete command syntax, see the man page.

4. Verify that all configured KMIP servers are connected:

```
security key-manager external show-status -node node_name
```

The security key-manager external show-status command replaces the security key-manager show -status command. For complete command syntax, see the man page.

```
cluster1::> security key-manager external show-status

Node    Vserver      Key Server                                Status
----  -----  -----
-----

8 entries were displayed.
```

= Enable external key management in ONTAP 9.5 and earlier
:icons: font
:relative_path: ./encryption-at-rest/

You can use one or more KMIP servers to secure the keys the cluster uses to access encrypted data. You can connect up to four KMIP servers to a node. A minimum of two servers is recommended for redundancy and disaster recovery.

What you'll need

- The KMIP SSL client and server certificates must have been installed.
- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure an external key manager.

About this task

ONTAP configures KMIP server connectivity for all nodes in the cluster.

Steps

1. Configure key manager connectivity for cluster nodes:

```
security key-manager setup
```

The key manager setup starts.

2. Enter the appropriate response at each prompt.
3. Add a KMIP server:

```
security key-manager add -address key_management_server_ipaddress
```

```
cluster1::> security key-manager add -address 20.1.1.1
```

4. Add an additional KMIP server for redundancy:

```
security key-manager add -address key_management_server_ipaddress
```

```
cluster1::> security key-manager add -address 20.1.1.2
```

5. Verify that all configured KMIP servers are connected:

```
security key-manager show -status
```

For complete command syntax, see the man page.

```
cluster1::> security key-manager show -status
```

Node	Port	Registered Key Manager	Status
cluster1-01	5696	20.1.1.1	available
cluster1-01	5696	20.1.1.2	available
cluster1-02	5696	20.1.1.1	available
cluster1-02	5696	20.1.1.2	available

= Manage keys with Azure Key Vault or Google Cloud KMS

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

:hardbreaks:

Beginning in ONTAP 9.10.1, you can use [Azure Key Vault \(AKV\)](#) and [Google Cloud Platform's Key Management Service \(Cloud KMS\)](#) to protect your ONTAP encryption keys in a Azure- or Google Cloud Platform-deployed application.

AKV and Cloud KMS can be used to protect [NetApp Volume Encryption \(NVE\) keys](#) only for data vservers.

Key management with AKV or Cloud KMS can be enabled with the CLI or the ONTAP REST API.

When using AKV or Cloud KMS, be aware that by default a data vserver LIF is used to communicate with the cloud key management endpoint. A node management network is used to communicate with the cloud provider's authentication services (login.microsoftonline.com for Azure; oauth2.googleapis.com for Cloud KMS). If the cluster network is not configured correctly, the cluster will not properly utilize the key management service.

Prerequisites

- The ONTAP cluster's nodes must support NVE
- Volume Encryption (VE) license installed
- Multi-tenant Encryption Key Management (MTEKM) license installed
- You must be a cluster or vserver administrator

Limitations

- AKV and Cloud KMS are not available for NSE and NAE. [External KMIPs](#) can be used instead
- AKV and Cloud KMS are not available for MetroCluster configurations.
- AKV and Cloud KMS can only be configured on a data vserver

== Enable external key management with the CLI

Azure

Enable AKV with the CLI

1. Before you begin, you need to obtain the appropriate authentication credentials from your Azure account, either a client secret or certificate.

You must also ensure all nodes in the cluster are healthy. You can check this with the command `cluster show`.

2. Set privileged level to advanced

```
set -priv advanced
```

3. Enable AKV on the SVM

```
security key-manager external azure enable -client-id client_id -tenant-id tenant_id -name -key-id key_id -authentication-method {certificate|client-secret}
```

When prompted, enter either the client certificate or client secret from your Azure account.

4. Verify AKV is enabled correctly:

```
security key-manager external azure show vserver vserver_name
```

If the service reachability is not OK, establish the connectivity to the AKV key management service via data vserver LIF.

Google Cloud

Enable Cloud KMS with the CLI

1. Before you begin, you need to obtain the private key for the Google Cloud KMS account key file in a JSON format. This can be found in your GCP account.

You must also ensure all nodes in the cluster are healthy. You can check this with the command `cluster show`.

2. Set privileged level to advanced

```
set -priv advanced
```

3. Enable Cloud KMS on the SVM

```
security key-manager external gcp enable -vserver data_svm_name -project-id project_id-key-ring-name key_ring_name -key-ring-location key_ring_location -key-name key_name
```

When prompted, enter the contents of the JSON file with the Service Account Private Key

4. Verify that Cloud KMS is configured with the correct parameters:

```
security key-manager external gcp show vserver vserver_name
```

The status of `kms_wrapped_key_status` will be "UNKNOWN" if no encrypted volumes have been created.

If the service reachability is not OK, establish the connectivity to the GCP key management service via data vserver LIF.

If one or more encrypted volumes is already configured for a data vserver and the corresponding NVE keys are managed by the admin vserver onboard key manager, those keys should be migrated to the external key management service. To do this with the CLI, run:

```
security key-manager key migrate -from-Vserver admin_vserver -to-Vserver
```

data_vserver

New encrypted volumes cannot be created for the tenant's data vserver until all NVE keys of the data vserver are successfully migrated.

= Enable onboard key management in ONTAP 9.6 and later (NVE)

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

What you'll need

- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure an external key manager.

About this task

You must run the `security key-manager onboard sync` command each time you add a node to the cluster.

If you have a MetroCluster configuration you must run `security key-manager onboard enable` on the local cluster first, then run `security key-manager onboard sync` on the remote cluster, using the same passphrase on each.

By default, you are not required to enter the key manager passphrase when a node is rebooted. You can use the `cc-mode-enabled=yes` option to require that users enter the passphrase after a reboot.

For NVE, if you set `cc-mode-enabled=yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. For `volume create`, you need not specify `-encrypt true`. For `volume move start`, you need not specify `-encrypt-destination true`.

When configuring ONTAP data at rest encryption, to meet the requirements for Commercial Solutions for Classified (CSfC) you must use NSE with NVE and ensure the Onboard Key Manager is enabled in Common Criteria mode. Refer to the [CSfC Solution Brief](#) for more information on CSfC.

When the Onboard Key Manager is enabled in Common Criteria mode (`cc-mode-enabled=yes`), system behavior is changed in the following ways:

- The system monitors for consecutive failed cluster passphrase attempts when operating in Common Criteria mode.

If you fail to enter the correct cluster passphrase at boot, encrypted volumes are not mounted. To correct this, you must reboot the node and enter the correct cluster passphrase. Once booted, the system allows up to 5 consecutive attempts to correctly enter the cluster passphrase in a 24-hour period for any command that requires the cluster passphrase as a parameter. If the limit is reached (for example, you have failed to correctly enter the cluster passphrase 5 times in a row) then you must either wait for the 24-hour timeout period to elapse, or you must reboot the node, in order to reset the limit.

- System image updates use the NetApp RSA-3072 code signing certificate together with SHA-384 code signed digests to check the image integrity instead of the usual NetApp RSA-2048 code signing certificate and SHA-256 code signed digests.

The upgrade command verifies that the image contents have not been altered or corrupted by checking various digital signatures. The image update process proceeds to the next step if validation succeeds; otherwise, the image update fails. See the “cluster image” man page for information concerning system updates.

The Onboard Key Manager stores keys in volatile memory. Volatile memory contents are cleared when the system is rebooted or halted. Under normal operating conditions, volatile memory contents will be cleared within 30s when a system is halted.

Steps

1. Start the key manager setup:

```
security key-manager onboard enable -cc-mode-enabled yes|no
```

Set `cc-mode-enabled=yes` to require that users enter the key manager passphrase after a reboot. For NVE, if you set `cc-mode-enabled=yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. The `- cc-mode-enabled` option is not supported in MetroCluster configurations. The `security key-manager onboard enable` command replaces the `security key-manager setup` command.

The following example starts the key manager setup command on `cluster1` without requiring that the passphrase be entered after every reboot:

```
cluster1::> security key-manager onboard enable

Enter the cluster-wide passphrase for onboard key management in
Vserver "cluster1":<32..256 ASCII characters long text>
Reenter the cluster-wide passphrase:<32..256 ASCII characters
long text>
```

2. At the passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

3. At the passphrase confirmation prompt, reenter the passphrase.

4. Verify that the authentication keys have been created:

```
security key-manager key query -key-type NSE-AK
```

The `security key-manager key query` command replaces the `security key-manager query key` command. For complete command syntax, see the man page.

The following example verifies that authentication keys have been created for `cluster1`:

```
cluster1::> security key-manager key query -key-type NSE-AK
      Vserver: cluster1
      Key Manager: onboard
      Node: node1

      Key Tag          Key Type  Restored

000000000000		

After you finish

Copy the passphrase to a secure location outside the storage system for future use.

All key management information is automatically backed up to the replicated database (RDB) for the cluster. You should also back up the information manually for use in case of a disaster.

= Enable onboard key management in ONTAP 9.5 and earlier (NVE)
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

What you'll need

- If you are using NSE with an external key management (KMIP) server, you must have deleted the external key manager database.

Transitioning to onboard key management from external key management

- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure the Onboard Key Manager.

About this task

You must run the `security key-manager setup` command each time you add a node to the cluster.

If you have a MetroCluster configuration, review these guidelines:

- In ONTAP 9.5, you must run `security key-manager setup` on the local cluster and `security key-manager setup -sync-metrocluster-config yes` on the remote cluster, using the same passphrase on each.
- Prior to ONTAP 9.5, you must run `security key-manager setup` on the local cluster, wait approximately 20 seconds, and then run `security key-manager setup` on the remote cluster, using the same passphrase on each.

By default, you are not required to enter the key manager passphrase when a node is rebooted. Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the passphrase after a reboot.

For NVE, if you set `-enable-cc-mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. For `volume create`, you need not specify `-encrypt true`. For `volume move start`, you need not specify `-encrypt-destination true`.

After a failed passphrase attempt, you must reboot the node again.

Steps

1. Start the key manager setup:

```
security key-manager setup -enable-cc-mode yes|no
```

Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the key manager passphrase after a reboot. For NVE, if you set `-enable-cc-mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted.

The following example starts setting up the key manager on cluster1 without requiring that the passphrase be entered after every reboot:

```
cluster1::> security key-manager setup  
Welcome to the key manager setup wizard, which will lead you through  
the steps to add boot information.
```

...

```
Would you like to use onboard key-management? {yes, no} [yes]:  
Enter the cluster-wide passphrase: <32..256 ASCII characters long  
text>  
Reenter the cluster-wide passphrase: <32..256 ASCII characters  
long text>
```

2. Enter yes at the prompt to configure onboard key management.
3. At the passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

4. At the passphrase confirmation prompt, reenter the passphrase.
5. Verify that keys are configured for all nodes:

```
security key-manager key show
```

For the complete command syntax, see the man page.

```
cluster1::> security key-manager key show

Node: node1
Key Store: onboard
Key ID

```

After you finish

Copy the passphrase to a secure location outside the storage system for future use.

All key management information is automatically backed up to the replicated database (RDB) for the cluster.

Whenever you configure the Onboard Key Manager passphrase, you should also back up the information manually to a secure location outside the storage system for use in case of a disaster. See [Back up onboard key management information manually](#).

= Enable onboard key management in newly added nodes
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/../media/

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

For ONTAP 9.5 and earlier, you must run the `security key-manager setup` command each time you add a node to the cluster.

For ONTAP 9.6 and later, you must run the `security key-manager sync` command each time you add a node to the cluster.

If you add a node to a cluster that has onboard key management configured, you will run this command to refresh the missing keys.

If you have a MetroCluster configuration, review these guidelines:

- Beginning with ONTAP 9.6, you must run `security key-manager onboard enable` on the local cluster first, then run `security key-manager onboard sync` on the remote cluster, using the same passphrase on each.
- In ONTAP 9.5, you must run `security key-manager setup` on the local cluster and `security key-manager setup -sync-metrocluster-config yes` on the remote cluster, using the same passphrase on each.
- Prior to ONTAP 9.5, you must run `security key-manager setup` on the local cluster, wait approximately 20 seconds, and then run `security key-manager setup` on the remote cluster, using the same passphrase on each.

By default, you are not required to enter the key manager passphrase when a node is rebooted.

Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the passphrase after a reboot.

For NVE, if you set `-enable-cc-mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. For `volume create`, you need not specify `-encrypt true`. For `volume move start`, you need not specify `-encrypt-destination true`.

After a failed passphrase attempt, you must reboot the node again.

= Encrypt volume data with NVE

= Encrypt volume data with NVE overview

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

Beginning with ONTAP 9.7, aggregate and volume encryption is enabled by default when you have the VE license and onboard or external key management. For ONTAP 9.6 and earlier, you can enable encryption on a new volume or on an existing volume. You must have installed the VE license and enabled key management before you can enable volume encryption. NVE is FIPS-140-2 level 1 compliant.

= Enable aggregate-level encryption with VE license

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

Beginning with ONTAP 9.7, newly created aggregates and volumes are encrypted by

default when you have the VE license and onboard or external key management. Beginning with ONTAP 9.6, you can use aggregate-level encryption to assign keys to the containing aggregate for the volumes to be encrypted. Volumes you create in the aggregate are encrypted by default. You can override the default when you encrypt the volume.

What you'll need

You must be a cluster administrator to perform this task.

About this task

You must use aggregate-level encryption if you plan to perform inline or background aggregate-level deduplication. Aggregate-level deduplication is otherwise not supported by NVE.

An aggregate enabled for aggregate-level encryption is called an *NAE aggregate* (for NetApp Aggregate Encryption). Plain text volumes are not supported in NAE aggregates.

Steps

1. Enable or disable aggregate-level encryption:

To...	Use this command...
Create an NAE aggregate with ONTAP 9.7 or later	<code>storage aggregate create -aggregate aggregate_name -node node_name</code>
Create an NAE aggregate with ONTAP 9.6	<code>storage aggregate create -aggregate aggregate_name -node node_name -encrypt-with-aggr-key true</code>
Convert a non-NAE aggregate to an NAE aggregate	<code>storage aggregate modify -aggregate aggregate_name -node node_name -encrypt-with-aggr-key true</code>
Convert an NAE aggregate to a non-NAE aggregate	<code>storage aggregate modify -aggregate aggregate_name -node node_name -encrypt-with-aggr-key false</code>

For complete command syntax, see the man pages.

The following command enables aggregate-level encryption on aggr1:

- ONTAP 9.7 or later:

```
cluster1::> storage aggregate create -aggregate aggr1
```

- ONTAP 9.6 or earlier:

```
cluster1::> storage aggregate create -aggregate aggr1 -encrypt  
-with-aggr-key true
```

2. Verify that the aggregate is enabled for encryption:

```
storage aggregate show -fields encrypt-with-aggr-key
```

For complete command syntax, see the man page.

The following command verifies that `aggr1` is enabled for encryption:

```
cluster1::> storage aggregate show -fields encrypt-with-aggr-key  
aggregate          encrypt-aggr-key  
-----  
-----  
aggr0_vsim4        false  
aggr1              true  
2 entries were displayed.
```

After you finish

Run the `volume create` command to create the encrypted volumes.

If you are using a KMIP server to store the encryption keys for a node, ONTAP automatically “pushes” an encryption key to the server when you encrypt a volume.

= Enable encryption on a new volume

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You can use the `volume create` command to enable encryption on a new volume.

About this task

Beginning with ONTAP 9.2, you can enable encryption on a SnapLock volume.

Beginning with ONTAP 9.4, if you enable “cc-mode” when you set up the Onboard Key Manager, volumes you create with the `volume create` command are automatically encrypted, whether or not you specify `-encrypt true`.

Beginning with ONTAP 9.6, you can use aggregate-level encryption to assign keys to the containing aggregate for the volumes to be encrypted. Volumes you create in the aggregate are encrypted by default. You can use the `-encrypt` option to override the default when you create the volume.

Beginning with ONTAP 9.7, newly created volumes are encrypted by default when you have the VE license and onboard or external key management.

A volume encrypted with a unique key is called an *NVE volume*. A volume encrypted with an aggregate-level key is called an *NAE aggregate* (for NetApp Aggregate Encryption). Plaintext volumes are not supported in NAE aggregates.

Steps

1. Create a new volume and specify whether encryption is enabled on the volume:

To create...	Use this command...
An ONTAP 9.7 or later NAE volume	volume create -vserver SVM_name -volume volume_name -aggregate aggregate_name
An ONTAP 9.6 NAE volume (assuming aggregate-level encryption is enabled)	volume create -vserver SVM_name -volume volume_name -aggregate aggregate_name
An ONTAP 9.7 or later NVE volume	volume create -vserver SVM_name -volume volume_name -aggregate aggregate_name
An ONTAP 9.6 or earlier NVE volume	volume create -vserver SVM_name -volume volume_name -aggregate aggregate_name -encrypt true
A plain text volume	volume create -vserver SVM_name -volume volume_name -aggregate aggregate_name -encrypt false

For complete command syntax, see the man page for the command.

Beginning with ONTAP 9.7 or later, the following command creates an NAE volume named `vol1` on `aggr1`:

```
cluster1::> volume create -vserver vs1 -volume vol1 -aggregate aggr1
```

Using ONTAP 9.6, assuming aggregate-level encryption is enabled, the following command creates an NAE volume named `vol1` on `aggr1`:

```
cluster1::> volume create -vserver vs1 -volume vol1 -aggregate aggr1
```

Beginning with ONTAP 9.7 or later, the following command creates an NVE volume named `vol2` on `aggr1`:

```
cluster1::> volume create -vserver vs1 -volume vol2 -aggregate aggr1
```

Using ONTAP 9.6 or earlier, the following command creates an NVE volume named `vol2` on `aggr1`:

```
cluster1::> volume create -vserver vs1 -volume vol2 -aggregate aggr1  
-encrypt true
```

The following command creates a plaintext volume named vol3 on aggr1:

```
cluster1::> volume create -vserver vs1 -volume vol3 -aggregate aggr1  
-encrypt false
```

2. Verify that volumes are enabled for encryption:

```
volume show -is-encrypted true
```

For complete command syntax, see the man page for the command.

The following command displays the encrypted volumes on cluster2:

```
cluster2::> volume show -is-encrypted true
```

Vserver	Volume	Aggregate	State	Type	Size	Available	Used
vs1	vol1	aggr2	online	RW	200GB	160.0GB	20%

Result

If you are using a KMIP server to store the encryption keys for a node, ONTAP automatically “pushes” an encryption key to the server when you encrypt a volume.

= Enable encryption on an existing volume with the volume encryption conversion start command
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./nas-audit/..media/

Beginning with ONTAP 9.3, you can use the volume encryption conversion start command to enable encryption of an existing volume "in place," without having to move the volume to a different location.

About this task

Once you start a conversion operation, it must complete. If you encounter a performance issue during the operation, you can run the volume encryption conversion pause command to pause the operation, and the volume encryption conversion resume command to resume the operation.

You cannot use volume encryption conversion start to convert a SnapLock volume.

Steps

1. Enable encryption on an existing volume:

```
volume encryption conversion start -vserver SVM_name -volume volume_name
```

For complete command syntax, see the man page for the command.

The following command enables encryption on the existing volume vol1:

```
cluster1::> volume encryption conversion start -vserver vs1 -volume vol1
```

The system creates an encryption key for the volume. The data on the volume is encrypted.

2. Verify the status of the conversion operation:

```
volume encryption conversion show
```

For complete command syntax, see the man page for the command.

The following command displays the status of the conversion operation:

```
cluster1::> volume encryption conversion show
```

Vserver	Volume	Start Time	Status
vs1	vol1	9/18/2017 17:51:41	Phase 2 of 2 is in progress.

3. When the conversion operation is complete, verify that the volume is enabled for encryption:

```
volume show -is-encrypted true
```

For complete command syntax, see the man page for the command.

The following command displays the encrypted volumes on cluster1:

```
cluster1::> volume show -is-encrypted true
```

Vserver	Volume	Aggregate	State	Type	Size	Available	Used
vs1	vol1	aggr2	online	RW	200GB	160.0GB	20%

Result

If you are using a KMIP server to store the encryption keys for a node, ONTAP automatically “pushes” an encryption key to the server when you encrypt a volume.

= Enable encryption on an existing volume with the volume move start command

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You can use the volume move start command to enable encryption by moving an existing volume. You must use volume move start in ONTAP 9.2 and earlier. You

can use the same aggregate or a different aggregate.

What you'll need

You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

Delegating authority to run the volume move command

About this task

You cannot use `volume move start` to enable encryption on a SnapLock or FlexGroup volume.

Beginning with ONTAP 9.4, if you enable “cc-mode” when you set up the Onboard Key Manager, volumes you create with the `volume move start` command are automatically encrypted. You need not specify `-encrypt-destination true`.

Beginning with ONTAP 9.6, you can use aggregate-level encryption to assign keys to the containing aggregate for the volumes to be moved. A volume encrypted with a unique key is called an *NVE volume*. A volume encrypted with an aggregate-level key is called an *NAE volume* (for NetApp Aggregate Encryption). Plaintext volumes are not supported in NAE aggregates.

Steps

1. Move an existing volume and specify whether encryption is enabled on the volume:

To convert...	Use this command...
A plaintext volume to an NVE volume	<code>volume move start -vserver SVM_name -volume volume_name -destination-aggregate aggregate_name -encrypt-destination true</code>
An NVE or plaintext volume to an NAE volume (assuming aggregate-level encryption is enabled on the destination)	<code>volume move start -vserver SVM_name -volume volume_name -destination-aggregate aggregate_name -encrypt-with-aggr-key true</code>
An NAE volume to an NVE volume	<code>volume move start -vserver SVM_name -volume volume_name -destination-aggregate aggregate_name -encrypt-with-aggr-key false</code>
An NAE volume to a plaintext volume	<code>volume move start -vserver SVM_name -volume volume_name -destination-aggregate aggregate_name -encrypt-destination false -encrypt-with-aggr-key false</code>
An NVE volume to a plaintext volume	<code>volume move start -vserver SVM_name -volume volume_name -destination-aggregate aggregate_name -encrypt-destination false</code>

For complete command syntax, see the man page for the command.

The following command converts a plaintext volume named `vol1` to an NVE volume:

```
cluster1::> volume move start -vserver vs1 -volume vol1 -destination  
-aggregate aggr2 -encrypt-destination true
```

Assuming aggregate-level encryption is enabled on the destination, the following command converts an NVE or plaintext volume named `vol1` to an NAE volume:

```
cluster1::> volume move start -vserver vs1 -volume vol1 -destination  
-aggregate aggr2 -encrypt-with-aggr-key true
```

The following command converts an NAE volume named `vol2` to an NVE volume:

```
cluster1::> volume move start -vserver vs1 -volume vol2 -destination  
-aggregate aggr2 -encrypt-with-aggr-key false
```

The following command converts an NAE volume named `vol2` to a plaintext volume:

```
cluster1::> volume move start -vserver vs1 -volume vol2 -destination  
-aggregate aggr2 -encrypt-destination false -encrypt-with-aggr-key  
false
```

The following command converts an NVE volume named `vol2` to a plaintext volume:

```
cluster1::> volume move start -vserver vs1 -volume vol2 -destination  
-aggregate aggr2 -encrypt-destination false
```

2. View the encryption type of cluster volumes:

```
volume show -fields encryption-type none|volume|aggregate
```

The `encryption-type` field is available in ONTAP 9.6 and later.

For complete command syntax, see the man page for the command.

The following command displays the encryption type of volumes in `cluster2`:

```
cluster2::> volume show -fields encryption-type

vserver    volume    encryption-type
-----  -----
vs1        vol1      none
vs2        vol2      volume
vs3        vol3      aggregate
```

3. Verify that volumes are enabled for encryption:

```
volume show -is-encrypted true
```

For complete command syntax, see the man page for the command.

The following command displays the encrypted volumes on cluster2:

```
cluster2::> volume show -is-encrypted true

Vserver    Volume    Aggregate    State    Type    Size    Available    Used
-----  -----  -----  -----  -----  -----  -----  -----
vs1        vol1      aggr2      online    RW    200GB    160.0GB    20%
```

Result

If you are using a KMIP server to store the encryption keys for a node, ONTAP automatically “pushes” an encryption key to the server when you encrypt a volume.

= Enable node root volume encryption
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

Beginning with ONTAP 9.8, you can use NetApp Volume Encryption to protect the root volume of your node.

What you'll need

- Your system must be using an HA configuration.
Root volume encryption is not supported on single node configurations.
- Your node root volume must already be created.
- Your system must have an onboard key manager or an external key management server using the Key Management Interoperability Protocol (KMIP).

About this task

This procedure applies to the node root volume. It does not apply to SVM root volumes. SVM root volumes can be protected through aggregate-level encryption.

Once root volume encryption begins, it must complete. You cannot pause the operation. Once encryption is complete, you cannot assign a new key to the root volume and you cannot perform a secure-purge operation.

Steps

1. Encrypt the root volume:

```
volume encryption conversion start -vserver SVM_name -volume root_vol_name
```

2. Verify the status of the conversion operation:

```
volume encryption conversion show
```

3. When the conversion operation is complete, verify that the volume is encrypted:

```
volume show -fields
```

The following shows example output for an encrypted volume.

```
::> volume show -vserver xyz -volume vol0 -fields is-encrypted
vserver      volume is-encrypted
-----
xyz          vol0    true
```

= Configure NetApp hardware-based encryption

= Configure NetApp hardware-based encryption overview

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/../media/

NetApp hardware-based encryption supports full-disk encryption (FDE) of data as it is written. The data cannot be read without an encryption key stored on the firmware. The encryption key, in turn, is accessible only to an authenticated node.

== Understanding NetApp hardware-based encryption

A node authenticates itself to a self-encrypting drive using an authentication key retrieved from an external key management server or Onboard Key Manager:

- The external key management server is a third-party system in your storage environment that serves keys to nodes using the Key Management Interoperability Protocol (KMIP). It is a best practice to configure external key management servers on a different storage system from your data.
- The Onboard Key Manager is a built-in tool that serves authentication keys to nodes from the same storage system as your data.

You can use NetApp Volume Encryption with hardware-based encryption to “double encrypt” data on self-encrypting drives.

AFF A220, AFF A800, FAS2720, FAS2750, and later systems store core dumps on their boot device. When self-encrypting drives are enabled on these systems, the core dump is also encrypted.

If an HA pair is using encrypting SAS or NVMe drives (SED, NSE, FIPS), you must follow the instructions in the topic [Returning a FIPS drive or SED to unprotected mode](#) for all drives within the HA pair prior to initializing the system (boot options 4 or 9). Failure to do this may result in future data loss if the drives are repurposed.

== Supported drive types

Two types of self-encrypting drive are supported:

- Self-encrypting FIPS-certified SAS or NVMe drives are supported on all FAS and AFF systems. These drives, called *FIPS drives*, conform to the requirements of Federal Information Processing Standard Publication 140-2, level 2. The certified capabilities enable protections in addition to encryption, such as preventing denial-of-service attacks on the drive. FIPS drives cannot be mixed with other types of drives on the same node or HA pair.
- Beginning with ONTAP 9.6, self-encrypting NVMe drives that have not undergone FIPS testing are supported on AFF A800 and A320 systems. These drives, called *SEDs*, offer the same encryption capabilities as FIPS drives, but can be mixed with non-SEDs on the same node or HA pair.

== When to use KMIP servers

Although it is less expensive and typically more convenient to use the onboard key manager, you should set up KMIP servers if any of the following are true:

- Your encryption key management solution must comply with FIPS 140-2 level 2 or higher.
- You need a multi-cluster solution, with centralized management of encryption keys.
- Your business requires the added security of storing authentication keys on a system or in a location different from the data.

== Support details

The following table shows important hardware encryption support details. See the Interoperability Matrix for the latest information about supported KMIP servers, storage systems, and disk shelves.

Resource or feature	Support details
Non-homogeneous disk sets	<ul style="list-style-type: none">• FIPS drives cannot be mixed with other types of drives on the same node or HA pair. Conforming HA pairs can coexist with non-conforming HA pairs in the same cluster.• SEDs can be mixed with non-SEDs on the same node or HA pair.
Drive type	<ul style="list-style-type: none">• FIPS drives can be SAS or NVMe drives.• SEDs must be NVMe drives.
10 Gb network interfaces	Beginning with ONTAP 9.3, KMIP key management configurations support 10 Gb network interfaces for communications with external key management servers.

Ports for communication with the key management server	Beginning with ONTAP 9.3, you can use any storage controller port for communication with the key management server. Otherwise, you should use port e0m for communication with key management servers. Depending on the storage controller model, certain network interfaces might not be available during the boot process for communication with key management servers.
MetroCluster (MCC)	<ul style="list-style-type: none"> NVMe drives support MCC. SAS drives do not support MCC.

= Hardware-based encryption workflow

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You must configure key management services before the cluster can authenticate itself to the self-encrypting drive. You can use an external key management server or an onboard key manager.

= Configure external key management overview

:icons: font

:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You can use one or more external key management servers to secure the keys that the cluster uses to access encrypted data. An external key management server is a third-party system in your storage environment that serves keys to nodes using the Key Management Interoperability Protocol (KMIP).

For ONTAP 9.1 and earlier versions, node management LIFs must be assigned to ports that are configured with the node management role before you can use the external key manager.

NetApp Volume Encryption (NVE) can be implemented with Onboard Key Manager in ONTAP 9.1 and later. In ONTAP 9.3 and later, NVE can be implemented with external key management (KMIP) and Onboard Key Manager.

= Collect network information in ONTAP 9.2 and earlier

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

If you are using ONTAP 9.2 or earlier, you should fill out the network configuration worksheet before enabling external key management.

Beginning with ONTAP 9.3, the system discovers all needed network information automatically.

Item	Notes	Value
Key management network interface name		
Key management network interface IP address	IP address of node management LIF, in IPv4 or IPv6 format	
Key management network interface IPv6 network prefix length	If you are using IPv6, the IPv6 network prefix length	
Key management network interface subnet mask		
Key management network interface gateway IP address		
IPv6 address for the cluster network interface	Required only if you are using IPv6 for the key management network interface	

Port number for each KMIP server	Optional. The port number must be the same for all KMIP servers. If you do not provide a port number, it defaults to port 5696, which is the Internet Assigned Numbers Authority (IANA) assigned port for KMIP.	
Key tag name	Optional. The key tag name is used to identify all keys belonging to a node. The default key tag name is the node name.

= Install SSL certificates on the cluster

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

The cluster and KMIP server use KMIP SSL certificates to verify each other's identity and establish an SSL connection. Before configuring the SSL connection with the KMIP server, you must install the KMIP client SSL certificates for the cluster, and the SSL public certificate for the root certificate authority (CA) of the KMIP server.

What you'll need

- The time must be synchronized on the server creating the certificates, the KMIP server, and the cluster.
- You must have obtained the public SSL KMIP client certificate for the cluster.
- You must have obtained the private key associated with the SSL KMIP client certificate for the cluster.

The SSL KMIP client certificate must not be password-protected.

- You must have obtained the SSL public certificate for the root certificate authority (CA) of the KMIP server.

You can install the client and server certificates on the KMIP server before or after installing the certificates on the cluster.

About this task

In an HA pair, both nodes must use the same public and private KMIP SSL certificates. If you connect multiple HA pairs to the same KMIP server, all nodes in the HA pairs must use the same public and private KMIP SSL certificates.

Steps

1. Install the SSL KMIP client certificates for the cluster:

```
security certificate install -vserver admin_svm_name -type client
```

You are prompted to enter the SSL KMIP public and private certificates.

```
cluster1::> security certificate install -vserver cluster1 -type client
```

2. Install the SSL public certificate for the root certificate authority (CA) of the KMIP server:

```
security certificate install -vserver admin_svm_name -type server-ca
```

```
cluster1::> security certificate install -vserver cluster1 -type server-ca
```

= Enable external key management in ONTAP 9.6 and later (HW-based)

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./nas-audit/..media/

You can use one or more KMIP servers to secure the keys the cluster uses to access encrypted data. You can connect up to four KMIP servers to a node. A minimum of two servers is recommended for redundancy and disaster recovery.

What you'll need

- The KMIP SSL client and server certificates must have been installed.
- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before you configure an external key manager.

Steps

1. Configure key manager connectivity for the cluster:

```
security key-manager external enable -vserver admin_SVM -key-servers  
host_name|IP_address:port,... -client-cert client_certificate -server-ca-  
cert server_CA_certificates
```

The `security key-manager external enable` command replaces the `security key-manager setup` command. You can run the `security key-manager external modify` command to change the external key management configuration. For complete command syntax, see the man pages.

The following command enables external key management for `cluster1` with three external key servers. The first key server is specified using its hostname and port, the second is specified using an IP address and the default port, and the third is specified using an IPv6 address and port:

```
cluster1::> security key-manager external enable -key-servers  
ks1.local:15696,10.0.0.10,[fd20:8b1e:b255:814e:32bd:f35c:832c:5a09]:  
1234 -client-cert AdminVserverClientCert -server-ca-certs  
AdminVserverServerCaCert
```

2. Verify that all configured KMIP servers are connected:

```
security key-manager external show-status -node node_name -vserver SVM -key
-server host_name|IP_address:port -key-server-status available|not-
responding|unknown
```

The `security key-manager external show-status` command replaces the `security key-manager show -status` command. For complete command syntax, see the man page.

```
cluster1::> security key-manager external show-status

Node    Vserver   Key Server                                Status

= Enable external key management in ONTAP 9.5 and earlier

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You can use one or more KMIP servers to secure the keys the cluster uses to access encrypted data. You can connect up to four KMIP servers to a node. A minimum of two servers is recommended for redundancy and disaster recovery.

What you'll need

- The KMIP SSL client and server certificates must have been installed.
- You must be a cluster administrator to perform this task.

- You must configure the MetroCluster environment before you configure an external key manager.

About this task

ONTAP configures KMIP server connectivity for all nodes in the cluster.

Steps

1. Configure key manager connectivity for cluster nodes:

```
security key-manager setup
```

The key manager setup starts.

2. Enter the appropriate response at each prompt.

3. Add a KMIP server:

```
security key-manager add -address key_management_server_ipaddress
```

```
cluster1::> security key-manager add -address 20.1.1.1
```

4. Add an additional KMIP server for redundancy:

```
security key-manager add -address key_management_server_ipaddress
```

```
cluster1::> security key-manager add -address 20.1.1.2
```

5. Verify that all configured KMIP servers are connected:

```
security key-manager show -status
```

For complete command syntax, see the man page.

```
cluster1::> security key-manager show -status
```

Node	Port	Registered Key Manager	Status
cluster1-01	5696	20.1.1.1	available
cluster1-01	5696	20.1.1.2	available
cluster1-02	5696	20.1.1.1	available
cluster1-02	5696	20.1.1.2	available

= Create authentication keys in ONTAP 9.6 and later

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.nas-audit/..media/

You can use the `security key-manager key create` command to create the

authentication keys for a node and store them on the configured KMIP servers.

What you'll need

You must be a cluster administrator to perform this task.

About this task

If your security setup requires you to use different keys for data authentication and FIPS 140-2 authentication, you should create a separate key for each. If that is not the case, you can use the same authentication key for FIPS compliance that you use for data access.

ONTAP creates authentication keys for all nodes in the cluster.

- This command is not supported when Onboard Key Manager is enabled. However, two authentication keys are created automatically when Onboard Key Manager is enabled. The keys can be viewed with the following command:

```
security key-manager key query -key-type NSE-AK
```

- You receive a warning if the configured key management servers are already storing more than 128 authentication keys.

You can use the `security key-manager key delete` command to delete any unused keys. The `security key-manager key delete` command fails if the given key is currently in use by ONTAP. (You must have privileges greater than “admin” to use this command.)

Steps

1. Create the authentication keys for cluster nodes:

```
security key-manager key create -key-tag passphrase_label -prompt-for-key true|false
```

Setting `prompt-for-key=true` causes the system to prompt the cluster administrator for the passphrase to use when authenticating encrypted drives. Otherwise, the system automatically generates a 32-byte passphrase. The `security key-manager key create` command replaces the `security key-manager create-key` command. For complete command syntax, see the man page.

The following example creates the authentication keys for `cluster1`, automatically generating a 32-byte passphrase:

```
cluster1::> security key-manager key create
Key ID:
0000000000000000200000000001006268333f870860128fbe17d393e5083b0000
000000000000
```

2. Verify that the authentication keys have been created:

```
security key-manager key query -node node
```

The security key-manager key query command replaces the security key-manager query key command. For complete command syntax, see the man page. The key ID displayed in the output is an identifier used to refer to the authentication key. It is not the actual authentication key or the data encryption key.

The following example verifies that authentication keys have been created for cluster1:

```
cluster1::> security key-manager key query
    Vserver: cluster1
    Key Manager: external
        Node: node1

    Key Tag                                Key Type   Restored
    -----                                -----   -----
node1                                     NSE-AK     yes
    Key ID:
00000000000000002000000000001000c11b3863f78c2273343d7ec5a67762e0000
000000000000
node1                                     NSE-AK     yes
    Key ID:
00000000000000002000000000001006f4e2513353a674305872a4c9f3bf7970000
000000000000

    Vserver: cluster1
    Key Manager: external
        Node: node2

    Key Tag                                Key Type   Restored
    -----                                -----   -----
node2                                     NSE-AK     yes
    Key ID:
00000000000000002000000000001000c11b3863f78c2273343d7ec5a67762e0000
000000000000
node2                                     NSE-AK     yes
    Key ID:
00000000000000002000000000001006f4e2513353a674305872a4c9f3bf7970000
000000000000
```

= Create authentication keys in ONTAP 9.5 and earlier

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.has-audit/../media/

You can use the security key-manager create-key command to create the authentication keys for a node and store them on the configured KMIP servers.

What you'll need

You must be a cluster administrator to perform this task.

About this task

If your security setup requires you to use different keys for data authentication and FIPS 140-2 authentication, you should create a separate key for each. If that is not the case, you can use the same authentication key for FIPS compliance that you use for data access.

ONTAP creates authentication keys for all nodes in the cluster.

- This command is not supported when onboard key management is enabled.
- You receive a warning if the configured key management servers are already storing more than 128 authentication keys.

You can use the key management server software to delete any unused keys, then run the command again.

Steps

1. Create the authentication keys for cluster nodes:

```
security key-manager create-key
```

For complete command syntax, see the man page for the command.

The key ID displayed in the output is an identifier used to refer to the authentication key. It is not the actual authentication key or the data encryption key.

The following example creates the authentication keys for cluster1:

```
cluster1::> security key-manager create-key
(security key-manager create-key)
Verifying requirements...

Node: cluster1-01
Creating authentication key...
Authentication key creation successful.
Key ID:
F1CB30AFF1CB30B0010100000000000A68B167F92DD54196297159B5968923C

Node: cluster1-01
Key manager restore operation initialized.
Successfully restored key information.

Node: cluster1-02
Key manager restore operation initialized.
Successfully restored key information.
```

2. Verify that the authentication keys have been created:

```
security key-manager query
```

For complete command syntax, see the man page.

The following example verifies that authentication keys have been created for cluster1:

```
cluster1::> security key-manager query

(security key-manager query)

      Node: cluster1-01
      Key Manager: 20.1.1.1
      Server Status: available

      Key Tag          Key Type  Restored
      -----          -----  -----
      cluster1-01      NSE-AK    yes

      Key ID:
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C

      Node: cluster1-02
      Key Manager: 20.1.1.1
      Server Status: available

      Key Tag          Key Type  Restored
      -----          -----  -----
      cluster1-02      NSE-AK    yes

      Key ID:
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
```

= Assign a data authentication key to a FIPS drive or SED (external key management)

You can use the `storage encryption disk modify` command to assign a data authentication key to a FIPS drive or SED. Cluster nodes use this key to lock or unlock encrypted data on the drive.

What you'll need

You must be a cluster administrator to perform this task.

About this task

A self-encrypting drive is protected from unauthorized access only if its authentication key ID is set to a non-default value. The manufacturer secure ID (MSID), which has key ID 0x0, is the standard default value for SAS drives. For NVMe drives, the standard default value is a null key, represented as a blank key ID. When you assign the key ID to a self-encrypting drive, the system changes its authentication key ID to a non-default value.

Steps

1. Assign a data authentication key to a FIPS drive or SED:

```
storage encryption disk modify -disk disk_ID -data-key-id key_ID
```

For complete command syntax, see the man page for the command.

You can use the security key-manager query -key-type NSE-AK command to view key IDs.

```
cluster1::> storage encryption disk modify -disk 0.10.* -data-key-id F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
```

Info: Starting modify on 14 disks.

View the status of the operation by using the storage encryption disk show-status command.

2. Verify that the authentication keys have been assigned:

```
storage encryption disk show
```

For complete command syntax, see the man page.

```
cluster1::> storage encryption disk show
Disk      Mode Data Key ID
-----  -----
-----
0.0.0    data
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
0.0.1    data
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
[...]
```

= Configure onboard key management

= Enable onboard key management in ONTAP 9.6 and later

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

You can use the Onboard Key Manager to authenticate cluster nodes to a FIPS drive or SED. The Onboard Key Manager is a built-in tool that serves authentication keys to nodes from the same storage system as your data. The Onboard Key Manager is FIPS-140-2 level 1 compliant.

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-

encrypting disk.

What you'll need

- If you are using NSE with an external key management (KMIP) server, you must have deleted the external key manager database.

Transitioning to onboard key management from external key management

- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before the Onboard key manager is configured.

About this task

You must run the `security key-manager onboard enable` command each time you add a node to the cluster. In MetroCluster configurations, you must run `security key-manager onboard enable` on the local cluster first, then run `security key-manager onboard sync` on the remote cluster, using the same passphrase on each.

By default, you are not required to enter the key manager passphrase when a node is rebooted. Except in MetroCluster, you can use the `cc-mode-enabled=yes` option to require that users enter the passphrase after a reboot.

When the Onboard Key Manager is enabled in Common Criteria mode (`cc-mode-enabled=yes`), system behavior is changed in the following ways:

- The system monitors for consecutive failed cluster passphrase attempts when operating in Common Criteria mode.

If NetApp Storage Encryption (NSE) is enabled and you fail to enter the correct cluster passphrase at boot, the system cannot authenticate to its drives and automatically reboots. To correct this, you must enter the correct cluster passphrase at the boot prompt. Once booted, the system allows up to 5 consecutive attempts to correctly enter the cluster passphrase in a 24-hour period for any command that requires the cluster passphrase as a parameter. If the limit is reached (for example, you have failed to correctly enter the cluster passphrase 5 times in a row) then you must either wait for the 24-hour timeout period to elapse, or you must reboot the node, in order to reset the limit.

- System image updates use the NetApp RSA-3072 code signing certificate together with SHA-384 code signed digests to check the image integrity instead of the usual NetApp RSA-2048 code signing certificate and SHA-256 code signed digests.

The upgrade command verifies that the image contents have not been altered or corrupted by checking various digital signatures. The image update process proceeds to the next step if validation succeeds; otherwise, the image update fails. See the “cluster image” man page for information concerning system updates.

 The Onboard Key Manager stores keys in volatile memory. Volatile memory contents are cleared when the system is rebooted or halted. Under normal operating conditions, volatile memory contents will be cleared within 30s when a system is halted.

Steps

1. Start the key manager setup command:

```
security key-manager onboard enable -cc-mode-enabled yes|no
```

Set `cc-mode-enabled=yes` to require that users enter the key manager passphrase after a reboot. The `- cc-mode-enabled` option is not supported in MetroCluster configurations. The `security key-manager onboard enable` command replaces the `security key-manager setup` command.

The following example starts the key manager setup command on `cluster1` without requiring that the passphrase be entered after every reboot:

```
cluster1::> security key-manager onboard enable
```

```
Enter the cluster-wide passphrase for onboard key management in  
Vserver "cluster1"::: <32..256 ASCII characters long text>  
Reenter the cluster-wide passphrase: <32..256 ASCII characters  
long text>
```

2. At the passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

3. At the passphrase confirmation prompt, reenter the passphrase.
4. Verify that the authentication keys have been created:

```
security key-manager key query -node node
```

The `security key-manager key query` command replaces the `security key-manager query key` command. For complete command syntax, see the man page.

The following example verifies that authentication keys have been created for `cluster1`:

```

cluster1::> security key-manager key query
    Vserver: cluster1
    Key Manager: onboard
        Node: node1

    Key Tag                                Key Type   Restored
    -----  -----  -----

000000000000

```

After you finish

Copy the passphrase to a secure location outside the storage system for future use.

All key management information is automatically backed up to the replicated database (RDB) for the cluster. You should also back up the information manually for use in case of a disaster.

= Enable onboard key management in ONTAP 9.5 and earlier
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./encryption-at-rest/..media/

You can use the Onboard Key Manager to authenticate cluster nodes to a FIPS drive or SED. The Onboard Key Manager is a built-in tool that serves authentication keys to nodes from the same storage system as your data. The Onboard Key Manager is FIPS-140-2 level 1 compliant.

You can use the Onboard Key Manager to secure the keys that the cluster uses to access encrypted data. You must enable Onboard Key Manager on each cluster that accesses an encrypted volume or a self-encrypting disk.

What you'll need

- If you are using NSE with an external key management (KMIP) server, you must have deleted the external key manager database.

[Transitioning to onboard key management from external key management](#)

- You must be a cluster administrator to perform this task.
- You must configure the MetroCluster environment before the Onboard Key Manager is configured.

About this task

You must run the `security key-manager setup` command each time you add a node to the cluster.

If you have a MetroCluster configuration, review these guidelines:

- In ONTAP 9.5, you must run `security key-manager setup` on the local cluster and `security key-manager setup -sync-metrocluster-config yes` on the remote cluster, using the same passphrase on each.
- Prior to ONTAP 9.5, you must run `security key-manager setup` on the local cluster, wait approximately 20 seconds, and then run `security key-manager setup` on the remote cluster, using the same passphrase on each.

By default, you are not required to enter the key manager passphrase when a node is rebooted.

Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the passphrase after a reboot.

For NVE, if you set `-enable-cc-mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted. For `volume create`, you need not specify `-encrypt true`. For `volume move start`, you need not specify `-encrypt-destination true`.

After a failed passphrase attempt, you must reboot the node again.

Steps

1. Start the key manager setup:

```
security key-manager setup -enable-cc-mode yes|no
```

Beginning with ONTAP 9.4, you can use the `-enable-cc-mode yes` option to require that users enter the key manager passphrase after a reboot. For NVE, if you set `-enable-cc-mode yes`, volumes you create with the `volume create` and `volume move start` commands are automatically encrypted.

The following example starts setting up the key manager on cluster1 without requiring that the passphrase be entered after every reboot:

```
cluster1::> security key-manager setup  
Welcome to the key manager setup wizard, which will lead you through  
the steps to add boot information.
```

...

```
Would you like to use onboard key-management? {yes, no} [yes]:  
Enter the cluster-wide passphrase: <32..256 ASCII characters long  
text>  
Reenter the cluster-wide passphrase: <32..256 ASCII characters  
long text>
```

2. Enter yes at the prompt to configure onboard key management.
3. At the passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.

If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.

4. At the passphrase confirmation prompt, reenter the passphrase.
5. Verify that keys are configured for all nodes:

```
security key-manager key show
```

For the complete command syntax, see the man page.

```
cluster1::> security key-manager key show

Node: node1

```

After you finish

All key management information is automatically backed up to the replicated database (RDB) for the cluster.

Whenever you configure the Onboard Key Manager passphrase, you should also back up the information manually to a secure location outside the storage system for use in case of a disaster. See [Back up onboard key management information manually](#).

= Assign a data authentication key to a FIPS drive or SED (onboard key management)
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./encryption-at-rest../media/

You can use the `storage encryption disk modify` command to assign a data authentication key to a FIPS drive or SED. Cluster nodes use this key to access data on the drive.

What you'll need

You must be a cluster administrator to perform this task.

About this task

A self-encrypting drive is protected from unauthorized access only if its authentication key ID is set to a non-default value. The manufacturer secure ID (MSID), which has key ID 0x0, is the standard default

value for SAS drives. For NVMe drives, the standard default value is a null key, represented as a blank key ID. When you assign the key ID to a self-encrypting drive, the system changes its authentication key ID to a non-default value.

Steps

1. Assign a data authentication key to a FIPS drive or SED:

```
storage encryption disk modify -disk disk_ID -data-key-id key_ID
```

For complete command syntax, see the man page for the command.

You can use the security key-manager query -key-type NSE-AK command to view key IDs.

```
cluster1::> storage encryption disk modify -disk 0.10.* -data-key-id  
000000000000000020000000000010019215b9738bc7b43d4698c80246db1f4
```

Info: Starting modify on 14 disks.

View the status of the operation by using the storage encryption disk show-status command.

2. Verify that the authentication keys have been assigned:

```
storage encryption disk show
```

For complete command syntax, see the man page.

```
cluster1::> storage encryption disk show  
Disk      Mode Data Key ID  
----      ---  
-----  
0.0.0    data  
000000000000000020000000000010019215b9738bc7b43d4698c80246db1f4  
0.0.1    data  
000000000000000020000000000010059851742AF2703FC91369B7DB47C4722  
[...]
```

= Assign a FIPS 140-2 authentication key to a FIPS drive

You can use the storage encryption disk modify command with the -fips -key-id option to assign a FIPS 140-2 authentication key to a FIPS drive. Cluster nodes use this key for drive operations other than data access, such as preventing denial-of-service attacks on the drive.

What you'll need

The drive firmware must support FIPS 140-2 compliance. The [NetApp Interoperability Matrix Tool](#)

contains information about supported drive firmware versions.

About this task

Your security setup may require you to use different keys for data authentication and FIPS 140-2 authentication. If that is not the case, you can use the same authentication key for FIPS compliance that you use for data access.

Steps

1. You must first ensure you have assigned a data authentication key. This can be done with using an [external key manager](#) or an [onboard key manager](#). Verify the key is assigned with the command `storage encryption disk show`.
2. Assign a FIPS 140-2 authentication key to SEDs:

```
storage encryption disk modify -disk disk_id -fips-key-id  
fips_authentication_key_id
```

You can use the `security key-manager query` command to view key IDs.

```
cluster1::> storage encryption disk modify -disk 2.10.* -fips-key-id  
6A1E21D80000000001000000000000005A1FB4EE8F62FD6D8AE6754C9019F35A
```

```
Info: Starting modify on 14 disks.
```

```
View the status of the operation by using the  
storage encryption disk show-status command.
```

3. Verify that the authentication key has been assigned:

```
storage encryption disk show -fips
```

For complete command syntax, see the man page.

```
cluster1::> storage encryption disk show -fips  
Disk      Mode FIPS-Compliance Key ID  
-----  ----  
-----  
2.10.0   full  
6A1E21D8000000000100000000000005A1FB4EE8F62FD6D8AE6754C9019F35A  
2.10.1   full  
6A1E21D8000000000100000000000005A1FB4EE8F62FD6D8AE6754C9019F35A  
[...]
```

= Enable cluster-wide FIPS-compliant mode for KMIP server connections

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./encryption-at-rest../media/

You can use the `security config modify` command with the `-is-fips-`

enabled option to enable cluster-wide FIPS-compliant mode for data in flight. Doing so forces the cluster to use OpenSSL in FIPS mode when connecting to KMIP servers.

What you'll need

- The storage controller must be configured in FIPS-compliant mode.
- All KMIP servers must support TLSv1.2. The system requires TLSv1.2 to complete the connection to the KMIP server when cluster-wide FIPS-compliant mode is enabled.

About this task

When you enable cluster-wide FIPS-compliant mode, the cluster will automatically use only TLS1.2 and FIPS-validated cipher suites. Cluster-wide FIPS-compliant mode is disabled by default.

You must reboot cluster nodes manually after modifying the cluster-wide security configuration.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. Verify that TLSv1.2 is supported:

```
security config show -supported-protocols
```

For complete command syntax, see the man page.

```
cluster1::> security config show
      Cluster
Cluster Security
Interface FIPS Mode  Supported Protocols      Supported Ciphers
Config Ready
-----
-----
SSL        false       TLSv1.2, TLSv1.1, TLSv1 ALL:!LOW:           yes
                           !aNULL:!EXP:
                           !eNULL
```

3. Enable cluster-wide FIPS-compliant mode:

```
security config modify -is-fips-enabled true -interface SSL
```

For complete command syntax, see the man page.

4. Reboot cluster nodes manually.

5. Verify that cluster-wide FIPS-compliant mode is enabled:

```
security config show
```

```

cluster1::> security config show
      Cluster
Cluster Security
Interface FIPS Mode   Supported Protocols      Supported Ciphers
Config Ready
-----
-----
SSL       true        TLSv1.2, TLSv1.1      ALL:!LOW:           yes
                                         !aNULL:!EXP:
                                         !eNULL:!RC4

```

= Manage NetApp encryption

= Unencrypt volume data

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

You can use the `volume move start` command to move and unencrypt volume data.

What you'll need

You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

[Delegating authority to run the volume move command](#)

Steps

1. Move an existing encrypted volume and unencrypt the data on the volume:

```

volume move start -vserver SVM_name -volume volume_name -destination
-aggregate aggregate_name -encrypt-destination false

```

For complete command syntax, see the man page for the command.

The following command moves an existing volume named `vol1` to the destination aggregate `aggr3` and unencrypts the data on the volume:

```

cluster1::> volume move start -vserver vs1 -volume vol1 -destination
-aggregate aggr3 -encrypt-destination false

```

The system deletes the encryption key for the volume. The data on the volume is unencrypted.

2. Verify that the volume is disabled for encryption:

```

volume show -encryption

```

For complete command syntax, see the man page for the command.

The following command displays whether volumes on cluster1 are encrypted:

```
cluster1::> volume show -encryption

Vserver    Volume    Aggregate    State    Encryption State
-----  -----  -----  -----  -----
vs1        vol1      aggr1      online    none
```

= Move an encrypted volume

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

You can use the `volume move start` command to move an encrypted volume. The moved volume can reside on the same aggregate or a different aggregate.

What you'll need

You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

[Delegating authority to run the volume move command](#)

About this task

The move will fail if the destination node or destination volume does not support volume encryption.

The `-encrypt-destination` option for `volume move start` defaults to true for encrypted volumes. Requiring you to specify explicitly that you do not want the destination volume to be encrypted ensures that you do not inadvertently unencrypt the data on the volume.

Steps

1. Move an existing encrypted volume and leave the data on the volume encrypted:

```
volume move start -vserver SVM_name -volume volume_name -destination
-aggregate aggregate_name
```

For complete command syntax, see the man page for the command.

The following command moves an existing volume named `vol1` to the destination aggregate `aggr3` and leaves the data on the volume encrypted:

```
cluster1::> volume move start -vserver vs1 -volume vol1 -destination
-aggregate aggr3
```

2. Verify that the volume is enabled for encryption:

```
volume show -is-encrypted true
```

For complete command syntax, see the man page for the command.

The following command displays the encrypted volumes on cluster1:

```
cluster1::> volume show -is-encrypted true

Vserver    Volume   Aggregate   State   Type   Size   Available   Used
-----  -----  -----  -----  -----  -----  -----  -----
vs1        vol1     aggr3      online   RW    200GB    160.0GB   20%
```

= Delegate authority to run the volume move command

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

You can use the `volume move` command to encrypt an existing volume, move an encrypted volume, or unencrypt a volume. Cluster administrators can run `volume move` command themselves, or they can delegate the authority to run the command to SVM administrators.

About this task

By default, SVM administrators are assigned the `vsadmin` role, which does not include the authority to move volumes. You must assign the `vsadmin-volume` role to SVM administrators to enable them to run the `volume move` command.

Step

1. Delegate authority to run the `volume move` command:

```
security login modify -vserver SVM_name -user-or-group-name
user_or_group_name -application application -authmethod
authentication_method -role vsadmin-volume
```

For complete command syntax, see the man page for the command.

The following command grants the SVM administrator authority to run the `volume move` command.

```
cluster1::>security login modify -vserver engData -user-or-group
-name SVM-admin -application ssh -authmethod domain -role vsadmin-
volume
```

= Change the encryption key for a volume with the `volume encryption rekey start` command

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

It is a security best practice to change the encryption key for a volume periodically. Beginning with ONTAP 9.3, you can use the `volume encryption rekey start` command to change the encryption key.

About this task

Once you start a rekey operation, it must complete. There is no returning to the old key. If you encounter a performance issue during the operation, you can run the `volume encryption rekey pause` command to pause the operation, and the `volume encryption rekey resume` command to resume the operation.

Until the rekey operation finishes, the volume will have two keys. New writes and their corresponding reads will use the new key. Otherwise, reads will use the old key.

You cannot use `volume encryption rekey start` to rekey a SnapLock volume.

Steps

1. Change an encryption key:

```
volume encryption rekey start -vserver SVM_name -volume volume_name
```

The following command changes the encryption key for `vol1` on `SVMvs1`:

```
cluster1::> volume encryption rekey start -vserver vs1 -volume vol1
```

2. Verify the status of the rekey operation:

```
volume encryption rekey show
```

For complete command syntax, see the man page for the command.

The following command displays the status of the rekey operation:

```
cluster1::> volume encryption rekey show
```

Vserver	Volume	Start Time	Status
-----	-----	-----	-----
vs1	vol1	9/18/2017 17:51:41	Phase 2 of 2 is in progress.

3. When the rekey operation is complete, verify that the volume is enabled for encryption:

```
volume show -is-encrypted true
```

For complete command syntax, see the man page for the command.

The following command displays the encrypted volumes on `cluster1`:

```

cluster1::> volume show -is-encrypted true

Vserver    Volume   Aggregate   State   Type   Size   Available   Used
-----  -----  -----  -----  -----  -----  -----  -----
vs1        vol1     aggr2      online   RW    200GB    160.0GB   20%

```

= Change the encryption key for a volume with the volume move start command

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

It is a security best practice to change the encryption key for a volume periodically. You can use the `volume move start` command to change the encryption key. You must use `volume move start` in ONTAP 9.2 and earlier. The moved volume can reside on the same aggregate or a different aggregate.

What you'll need

You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

[Delegating authority to run the volume move command](#)

About this task

You cannot use `volume move start` to rekey a SnapLock or FlexGroup volume.

Steps

1. Move an existing volume and change the encryption key:

```

volume move start -vserver SVM_name -volume volume_name -destination
-aggregate aggregate_name -generate-destination-key true

```

For complete command syntax, see the man page for the command.

The following command moves an existing volume named **vol1** to the destination aggregate **aggr2** and changes the encryption key:

```

cluster1::> volume move start -vserver vs1 -volume vol1 -destination
-aggregate aggr2 -generate-destination-key true

```

A new encryption key is created for the volume. The data on the volume remains encrypted.

2. Verify that the volume is enabled for encryption:

```

volume show -is-encrypted true

```

For complete command syntax, see the man page for the command.

The following command displays the encrypted volumes on `cluster1`:

```

cluster1::> volume show -is-encrypted true

Vserver    Volume   Aggregate   State   Type   Size   Available   Used
-----  -----  -----  -----  -----  -----  -----  -----
vs1        vol1     aggr2      online   RW    200GB    160.0GB   20%

```

= Rotate authentication keys for NetApp Storage Encryption

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

You can rotate authentication keys when using NetApp Storage Encryption (NSE).

About this task

Rotating authentication keys in an NSE environment is supported if you are using External Key Manager (KMIP).

Rotating authentication keys in an NSE environment is not supported for Onboard Key Manager (OKM).

Steps

1. Use the `security key-manager create-key` command to generate new authentication keys.

You need to generate new authentication keys before you can change the authentication keys.

2. Use the `storage encryption disk modify -disk * -data-key-id` command to change the authentication keys.

= Delete an encrypted volume

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

You can use the `volume delete` command to delete an encrypted volume.

What you'll need

- You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

[Delegating authority to run the volume move command](#)

- The volume must be offline.

Step

1. Delete an encrypted volume:

```
volume delete -vserver SVM_name -volume volume_name
```

For complete command syntax, see the man page for the command.

The following command deletes an encrypted volume named vol1:

```
cluster1::> volume delete -vserver vs1 -volume vol1
```

Enter yes when you are prompted to confirm deletion.

The system deletes the encryption key for the volume after 24 hours.

Use `volume delete` with the `-force true` option to delete a volume and destroy the corresponding encryption key immediately. This command requires advanced privileges. For more information, see the man page.

After you finish

You can use the `volume recovery-queue` command to recover a deleted volume during the retention period after issuing the `volume delete` command:

```
volume recovery-queue SVM_name -volume volume_name
```

How to use the Volume Recovery feature

= Securely purge data on an encrypted volume

= Securely purge data on an encrypted volume overview

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

Beginning with ONTAP 9.4, you can use secure purge to non-disruptively scrub data on NVE-enabled volumes. Scrubbing data on an encrypted volume ensures that it cannot be recovered from the physical media, for example, in cases of “spillage,” where data traces may have been left behind when blocks were overwritten, or for securely deleting a vacating tenant’s data.

Secure purge works only for previously deleted files on NVE-enabled volumes. You cannot scrub an unencrypted volume. You must use KMIP servers to serve keys, not the onboard key manager.

Secure purge functions differently depending upon your version of ONTAP.

- In ONTAP 9.8 and later:
 - Secure purge is supported by MetroCluster and FlexGroup.
 - If the volume being purged is the source of a SnapMirror relationship, you do not have to break the SnapMirror relationship to perform a secure purge.
 - The re-encryption method is different for volumes using SnapMirror data protection versus volumes not using SnapMirror data protection (DP) or those using SnapMirror extended data protection..
 - By default, volumes using SnapMirror data protection (DP) mode re-encrypt data using the volume move re-encryption method.
 - By default, volumes not using SnapMirror data protection or volumes using SnapMirror

extended data protection (XDP) mode use the in-place re-encryption method.

- These defaults can be changed using the `secure purge re-encryption-method [volume-move|in-place-rekey]` command.
- By default, all Snapshot copies in FlexVol volumes are automatically deleted during the secure purge operation. By default, Snapshots in FlexGroup volumes and volumes using SnapMirror data protection are not automatically deleted during the secure purge operation. These defaults can be changed using the `secure purge delete-all-snapshots [true|false]`. command.
- In ONTAP 9.7 and earlier:
 - Secure purge does not support the following:
 - FlexClone
 - SnapVault
 - FabricPool
 - If the volume being purged is the source of a SnapMirror relationship, you must break the SnapMirror relationship before you can purge the volume.
If there are busy Snapshot copies in the volume, you must release the Snapshot copies before you can purge the volume. For example, you may need to split a FlexClone volume from its parent.
- Successfully invoking the secure-purge feature triggers a volume move that re-encrypts the remaining, unpurged data with a new key.
The moved volume remains on the current aggregate. The old key is automatically destroyed, ensuring that purged data cannot be recovered from the storage media.

= Securely purge data on an encrypted volume without a SnapMirror relationship

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

Beginning with ONTAP 9.4, you can use secure-purge to non-disruptively “scrub” data on NVE-enabled volumes.

What you'll need

- You must be a cluster administrator to perform this task.
- Advanced privileges are required for this task.

About this task

Secure-purge may take from several minutes to many hours to complete, depending on the amount of data in the deleted files. You can use the `volume encryption secure-purge show` command to view the status of the operation. You can use the `volume encryption secure-purge abort` command to terminate the operation.

In order to do a secure purge on a SAN host, you must delete the entire LUN containing the files you want to purge, or you must be able to punch holes in the LUN for the blocks that belong to the files you want purge. If you cannot delete the LUN or your host operating system does not support punching holes in the LUN, you cannot perform a secure purge.

Steps

1. Delete the files or the LUN you want to securely purge.
 - On a NAS client, delete the files you want to securely purge.
 - On a SAN host, delete the LUN you want to securely purge or punch holes in the LUN for the blocks that belong to the files you want to purge.
2. On the storage system, change to advanced privilege level:

```
set -privilege advanced
```

3. If the files you want to securely purge are in snapshots, delete the snapshots:

```
snapshot delete -vserver SVM_name -volume vol_name -snapshot
```

4. Securely purge the deleted files:

```
volume encryption secure-purge start -vserver SVM_name -volume volume_name
```

The following command securely purges the deleted files on `vol1` on `SVMvs1`:

```
cluster1::> volume encryption secure-purge start -vserver vs1  
-volume vol1
```

5. Verify the status of the secure-purge operation:

```
volume encryption secure-purge show
```

= Securely purge data on an encrypted volume with an Asynchronous SnapMirror relationship

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

Beginning with ONTAP 9.8, you can use a secure purge to non-disruptively “scrub” data on NVE-enabled volumes with an Asynchronous SnapMirror relationship.

What you'll need

- You must be a cluster administrator to perform this task.
- Advanced privileges are required for this task.

About this task

Secure-purge may take from several minutes to many hours to complete, depending on the amount of data in the deleted files. You can use the `volume encryption secure-purge show` command to view the status of the operation. You can use the `volume encryption secure-purge abort` command to terminate the operation.

In order to do a secure purge on a SAN host, you must delete the entire LUN containing the files you want to purge, or you must be able to punch holes in the LUN for the blocks that belong to the files you want purge. If you cannot delete the LUN or your host operating system does not support punching holes in the LUN, you cannot perform a secure purge.

Steps

1. On the storage system, change to advanced privilege level:

```
set -privilege advanced
```

2. Delete the files or the LUN you want to securely purge.

- On a NAS client, delete the files you want to securely purge.
- On a SAN host, delete the LUN you want to securely purge or punch holes in the LUN for the blocks that belong to the files you want to purge.

3. Prepare the destination volume in the Asynchronous relationship to be securely purged:

```
volume encryption secure-purge start -vserver SVM_name -volume volume_name  
-prepare true
```

Repeat this step on each volume in your Asynchronous SnapMirror relationship.

4. If the files you want to securely purge are in Snapshot copies, delete the Snapshot copies:

```
snapshot delete -vserver SVM_name -volume vol_name -snapshot
```

5. If the files you want to securely purge are in the base Snapshot copies, do the following:

- a. Create a Snapshot copy on the destination volume in the Asynchronous SnapMirror relationship:

```
volume snapshot create -snapshot snapshot_name -vserver SVM_name -volume  
vol_name
```

- b. Update SnapMirror to move the base Snapshot copy forward:

```
snapmirror update -source-snapshot snapshot_name -destination-path  
destination_path
```

Repeat this step for each volume in the Asynchronous SnapMirror relationship.

- c. Repeat steps (a) and (b) equal to the number of base Snapshot copies plus one.

For example, if you have two base Snapshot copies, you should repeat steps (a) and (b) three times.

- d. Verify that the base Snapshot copy is present:

```
snapshot show -vserver SVM_name -volume vol_name`
```

- e. Delete the base Snapshot copy:

```
snapshot delete -vserver SVM_name -volume vol_name -snapshot snapshot
```

6. Securely purge the deleted files:

```
volume encryption secure-purge start -vserver SVM_name -volume volume_name
```

Repeat this step on each volume in the Asynchronous SnapMirror relationship.

The following command securely purges the deleted files on “vol1” on SVM “vs1”:

```
cluster1::> volume encryption secure-purge start -vserver vs1  
-volume vol1
```

7. Verify the status of the secure purge operation:

```
volume encryption secure-purge show
```

= Scrub data on an encrypted volume with a Synchronous SnapMirror relationship
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

Beginning with ONTAP 9.8, you can use a secure purge to non-disruptively “scrub” data on NVE-enabled volumes with a Synchronous SnapMirror relationship.

What you'll need

- You must be a cluster administrator to perform this task.
- Advanced privileges are required for this task.

About this task

A secure purge might take from several minutes to many hours to complete, depending on the amount of data in the deleted files. You can use the `volume encryption secure-purge show` command to view the status of the operation. You can use the `volume encryption secure-purge abort` command to terminate the operation.

In order to do a secure purge on a SAN host, you must delete the entire LUN containing the files you want to purge, or you must be able to punch holes in the LUN for the blocks that belong to the files you want purge. If you cannot delete the LUN or your host operating system does not support punching holes in the LUN, you cannot perform a secure purge.

Steps

1. On the storage system, change to advanced privilege level:

```
set -privilege advanced
```

2. Delete the files or the LUN you want to securely purge.

- On a NAS client, delete the files you want to securely purge.
- On a SAN host, delete the LUN you want to securely purge or punch holes in the LUN for the blocks that belong to the files you want to purge.

3. Prepare the destination volume in the Asynchronous relationship to be securely purged:

```
volume encryption secure-purge start -vserver SVM_name -volume volume_name  
-prepare true
```

Repeat this step for the other volume in your Synchronous SnapMirror relationship.

4. If the files you want to securely purge are in Snapshot copies, delete the Snapshot copies:

```
snapshot delete -vserver SVM_name -volume vol_A -snapshot snapshot
```

5. If the secure purge file is in the base or common Snapshot copies, update the SnapMirror to move the common Snapshot copy forward:

```
snapmirror update -source-snapshot snapshot_name -destination-path destination_path
```

There are two common Snapshot copies, so this command must be issued twice.

6. If the secure purge file is in the application-consistent Snapshot copy, delete the Snapshot copy on both volumes in the Synchronous SnapMirror relationship:

```
snapshot delete -vserver SVM_name -volume vol_name -snapshot snapshot
```

Perform this step on both volumes.

7. Securely purge the deleted files:

```
volume encryption secure-purge start -vserver SVM_name -volume volume_name
```

Repeat this step on each volume in the synchronous SnapMirror relationship.

The following command securely purges the deleted files on “vol1” on SMV “vs1”.

```
cluster1::> volume encryption secure-purge start -vserver vs1  
-volume vol1
```

8. Verify the status of the secure purge operation:

```
volume encryption secure-purge show
```

= Change the onboard key management passphrase

It is a security best practice to change the onboard key management passphrase periodically. You should copy the new onboard key management passphrase to a secure location outside the storage system for future use.

What you'll need

- You must be a cluster or SVM administrator to perform this task.
- Advanced privileges are required for this task.

Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Change the onboard key management passphrase:

For this ONTAP version...	Use this command...
ONTAP 9.6 and later	security key-manager onboard update-passphrase
ONTAP 9.5 and earlier	security key-manager update-passphrase

For complete command syntax, see the man pages.

The following ONTAP 9.6 command lets you change the onboard key management passphrase for cluster1:

```
cluster1::> security key-manager onboard update-passphrase
Warning: This command will reconfigure the cluster passphrase for
onboard key management for Vserver "cluster1".
Do you want to continue? {y|n}: y
Enter current passphrase:
Enter new passphrase:
```

3. Enter y at the prompt to change the onboard key management passphrase.
 4. Enter the current passphrase at the current passphrase prompt.
 5. At the new passphrase prompt, enter a passphrase between 32 and 256 characters, or for “cc-mode”, a passphrase between 64 and 256 characters.
- If the specified “cc-mode” passphrase is less than 64 characters, there is a five-second delay before the key manager setup operation displays the passphrase prompt again.
6. At the passphrase confirmation prompt, reenter the passphrase.

After you finish

In a MetroCluster environment, you must update the passphrase on the partner cluster:

- In ONTAP 9.5 and earlier, you must run `security key-manager update-passphrase` with the same passphrase on the partner cluster.
- In ONTAP 9.6 and later, you are prompted to run `security key-manager onboard sync` with the same passphrase on the partner cluster.

You should copy the onboard key management passphrase to a secure location outside the storage system for future use.

You should back up key management information manually whenever you change the onboard key management passphrase.

[Backing up onboard key management information manually](#)

= Back up onboard key management information manually

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..../media/

You should copy onboard key management information to a secure location outside the storage system whenever you configure the Onboard Key Manager passphrase.

What you'll need

- You must be a cluster administrator to perform this task.
- Advanced privileges are required for this task.

About this task

All key management information is automatically backed up to the replicated database (RDB) for the cluster. You should also back up key management information manually for use in case of a disaster.

Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Display the key management backup information for the cluster:

For this ONTAP version...	Use this command...
ONTAP 9.6 and later	security key-manager onboard show-backup
ONTAP 9.5 and earlier	security key-manager backup show

For complete command syntax, see the man pages.

+

The following 9.6 command displays the key management backup information for `cluster1`:

+

```
cluster1::> security key-manager onboard show-backup
```

1. Copy the backup information to a secure location outside the storage system for use in case of a disaster.

= Restore onboard key management encryption keys

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..../media/

If need to restore an onboard key management encryption key, you first verify that a key needs to be restored, then you can set up the Onboard Key Manager to restore the key.

What you'll need

- If you are using NSE with an external key management (KMIP) server, you must have deleted the external key manager database.

[Transitioning to onboard key management from external key management](#)

- You must be a cluster administrator to perform this task.

== Steps for ONTAP 9.6 and later

1. Verify that the key needs to be restored:

```
security key-manager key query -node node
```

2. If you are running ONTAP 9.8 and later, and your root volume is encrypted, complete [\[root_volume_encrypted\]](#).

If you are running ONTAP 9.6 or 9.7, or if you are running ONTAP 9.8 or later and your root volume is not encrypted, skip this step.

3. Restore the key:

```
security key-manager onboard sync
```

For complete command syntax, see the man pages.

The following ONTAP 9.6 command synchronize the keys in the onboard key hierarchy:

```
cluster1::> security key-manager onboard sync
```

```
Enter the cluster-wide passphrase for onboard key management in
Vserver "cluster1":<32..256 ASCII characters long text>
```

4. At the passphrase prompt, enter the onboard key management passphrase for the cluster.

== Steps for ONTAP 9.5 and earlier

1. Verify that the key needs to be restored:

```
security key-manager key show
```

2. If you are running ONTAP 9.8 and later, and your root volume is encrypted, complete these steps:

If you are running ONTAP 9.6 or 9.7, or if you are running ONTAP 9.8 or later and your root volume is not encrypted, skip this step.

3. Restore the key:

```
security key-manager setup -node node
```

For complete command syntax, see the man pages.

4. At the passphrase prompt, enter the onboard key management passphrase for the cluster.

== Steps if the root volume is encrypted

If you are running ONTAP 9.8 and later, and your root volume is encrypted, you must set an onboard key management recovery passphrase with the boot menu.

1. Boot the node to the boot menu and select option (10) Set onboard key management recovery secrets.
2. Enter **y** to use this option.
3. At the prompt, enter the onboard key management passphrase for the cluster.
4. At the prompt, enter the backup key data.

The node returns to the boot menu.

5. From the boot menu, select option (1) Normal Boot.

```
= Restore external key management encryption keys
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/
```

You can manually restore external key management encryption keys and “push” them to a different node. You might want to do this if you are restarting a node that was down temporarily when you created the keys for the cluster.

What you'll need

You must be a cluster or SVM administrator to perform this task.

About this task

In ONTAP 9.6 and later, you can use the `security key-manager key query -node node_name` command to verify if your key needs to be restored.

In ONTAP 9.5 and earlier, you can use the `security key-manager key show` command to verify if your key needs to be restored.

Steps

1. If you are running ONTAP 9.8 or later and your root volume is encrypted, do the following:

If you are running ONTAP 9.7 or earlier, or if you are running ONTAP 9.8 or later and your root volume is not encrypted, skip this step.

- a. Set the bootargs:

```
setenv kmip.init.ipaddr <ip-address>
setenv kmip.init.netmask <netmask>
setenv kmip.init.gateway <gateway>
setenv kmip.init.interface e0M
boot_ontap
```

- b. Boot the node to the boot menu and select option (11) Configure node for external key management.
- c. Follow prompts to enter management certificate.

After all management certificate information is entered, the system returns to the boot menu.

- d. From the boot menu, select option (1) Normal Boot.
2. Restore the key:

For this ONTAP version...	Use this command...
ONTAP 9.6 and later	<pre>security key-manager external restore -vserver SVM -node node -key-server host_name IP_address:port -key-id key_id -key -tag key_tag</pre>
ONTAP 9.5 and earlier	<pre>security key-manager restore -node node -address IP_address -key-id key_id -key-tag key_tag</pre>

node defaults to all nodes. For complete command syntax, see the man pages. This command is not supported when onboard key management is enabled.

The following ONTAP 9.6 command restores external key management authentication keys to all nodes in cluster1:

```
cluster1::> security key-manager external restore
```

= Replace SSL certificates

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

All SSL certificates have an expiration date. You must update your certificates before they expire to prevent loss of access to authentication keys.

What you'll need

- You must have obtained the replacement public certificate and private key for the cluster (KMIP client certificate).
- You must have obtained the replacement public certificate for the KMIP server (KMIP server-ca certificate).
- You must be a cluster or SVM administrator to perform this task.

You can install the replacement client and server certificates on the KMIP server before or after installing the certificates on the cluster.

Steps

1. Install the new KMIP server-ca certificate:

```
security certificate install -type server-ca -vserver <>
```

2. Install the new KMIP client certificate:

```
security certificate install -type client -vserver <>
```

3. Update the key manager configuration to use the newly installed certificates:

```
security key-manager external modify -vserver <> -client-cert <> -server-ca-certs <>
```

Updating the key manager configuration to use the newly installed certificates will return an error if the public/private keys of the new client certificate are different from the keys previously installed. Contact NetApp support for instructions on how to override this error.

= Replace a FIPS drive or SED

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

You can replace a FIPS drive or SED the same way you replace an ordinary disk. Make sure to assign new data authentication keys to the replacement drive. For a FIPS drive, you may also want to assign a new FIPS 140-2 authentication key.

If an HA pair is using [encrypting SAS or NVMe drives \(SED, NSE, FIPS\)](#), you must follow the instructions in the topic [Returning a FIPS drive or SED to unprotected mode](#) for all drives within the HA pair prior to initializing the system (boot options 4 or 9). Failure to do this may result in future data loss if the drives are repurposed.

What you'll need

- You must know the key ID for the authentication key used by the drive.
- You must be a cluster administrator to perform this task.

Steps

1. Ensure that the disk has been marked as failed:

```
storage disk show -broken
```

For complete command syntax, see the man page.

```

cluster1::> storage disk show -broken
Original Owner: cluster1-01
Checksum Compatibility: block

Usable Physical
  Disk    Outage Reason HA Shelf Bay Chan   Pool   Type      RPM
Size     Size

-----
-----  -----
  0.0.0  admin  failed  0b      1    0     A  Pool0  FCAL  10000
132.8GB 133.9GB
  0.0.7  admin  removed 0b      2    6     A  Pool1  FCAL  10000
132.8GB 134.2GB
[...]

```

2. Remove the failed disk and replace it with a new FIPS drive or SED, following the instructions in the hardware guide for your disk shelf model.
3. Assign ownership of the newly replaced disk:

```
storage disk assign -disk disk_name -owner node
```

For complete command syntax, see the man page.

```
cluster1::> storage disk assign -disk 2.1.1 -owner cluster1-01
```

4. Confirm that the new disk has been assigned:

```
storage encryption disk show
```

For complete command syntax, see the man page.

```

cluster1::> storage encryption disk show
Disk      Mode Data Key ID
----  ----
-----
0.0.0    data
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
0.0.1    data
F1CB30AFF1CB30B0010100000000000A68B167F92DD54196297159B5968923C
1.10.0   data
F1CB30AFF1CB30B0010100000000000CF0EFD81EA9F6324EA97B369351C56AC
1.10.1   data
F1CB30AFF1CB30B0010100000000000CF0EFD81EA9F6324EA97B369351C56AC
2.1.1    open 0x0
[...]

```

5. Assign the data authentication keys to the FIPS drive or SED.

[Assigning a data authentication key to a FIPS drive or SED \(external key management\)](#)

6. If necessary, assign a FIPS 140-2 authentication key to the FIPS drive.

[Assigning a FIPS 140-2 authentication key to a FIPS drive](#)

= Make data on a FIPS drive or SED inaccessible

= Make data on a FIPS drive or SED inaccessible overview

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

If you want to make data on a FIPS drive or SED permanently inaccessible, but keep the drive's unused space available for new data, you can sanitize the disk. If you want to make data permanently inaccessible and you do not need to reuse the drive, you can destroy it.

- Disk sanitization

When you sanitize a self-encrypting drive, the system changes the disk encryption key to a new random value, resets the power-on lock state to false, and sets the key ID to a default value, either the manufacturer secure ID 0x0 (SAS drives) or a null key (NVMe drives). Doing so renders the data on the disk inaccessible and impossible to retrieve. You can reuse sanitized disks as non-zeroed spare disks.

- Disk destroy

When you destroy a FIPS drive or SED, the system sets the disk encryption key to an unknown random value and locks the disk irreversibly. Doing so renders the disk permanently unusable and the data on it permanently inaccessible.

You can sanitize or destroy individual self-encrypting drives, or all the self-encrypting drives for a node.

= Sanitize a FIPS drive or SED

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

If you want to make data on a FIPS drive or SED permanently inaccessible, and use the drive for new data, you can use the `storage encryption disk sanitize` command to sanitize the drive.

What you'll need

You must be a cluster administrator to perform this task.

About this task

When you sanitize a self-encrypting drive, the system changes the disk encryption key to a new random value, resets the power-on lock state to false, and sets the key ID to a default value, either the manufacturer secure ID 0x0 (SAS drives) or a null key (NVMe drives). Doing so renders the data on the disk inaccessible and impossible to retrieve. You can reuse sanitized disks as non-zeroed spare disks.

Steps

1. Migrate any data that needs to be preserved to an aggregate on another disk.
2. Delete the aggregate on the FIPS drive or SED to be sanitized:

```
storage aggregate delete -aggregate aggregate_name
```

For complete command syntax, see the man page.

```
cluster1::> storage aggregate delete -aggregate aggr1
```

3. Identify the disk ID for the FIPS drive or SED to be sanitized:

```
storage encryption disk show -fields data-key-id,fips-key-id,owner
```

For complete command syntax, see the man page.

```
cluster1::> storage encryption disk show
Disk      Mode Data Key ID
-----  -----
-----
0.0.0    data
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
0.0.1    data
F1CB30AFF1CB30B001010000000000A68B167F92DD54196297159B5968923C
1.10.2   data
F1CB30AFF1CB30B001010000000000CF0EFD81EA9F6324EA97B369351C56AC
[...]
```

4. If a FIPS drive is running in FIPS-compliance mode, set the FIPS authentication key ID for the node back to the default MSID 0x0:

```
storage encryption disk modify -disk disk_id -fips-key-id 0x0
```

You can use the security key-manager query command to view key IDs.

```
cluster1::> storage encryption disk modify -disk 1.10.2 -fips-key-id 0x0
```

Info: Starting modify on 1 disk.

View the status of the operation by using the storage encryption disk show-status command.

5. Sanitize the drive:

```
storage encryption disk sanitize -disk disk_id
```

You can use this command to sanitize hot spare or broken disks only. To sanitize all disks regardless of type, use the -force-all-state option. For complete command syntax, see the man page.

You are prompted to enter a confirmation phrase before continuing. Enter the phrase exactly as shown on the screen.

```
cluster1::> storage encryption disk sanitize -disk 1.10.2
```

Warning: This operation will cryptographically sanitize 1 spare or broken self-encrypting disk on 1 node.

To continue, enter sanitize disk: sanitize disk

Info: Starting sanitize on 1 disk.

View the status of the operation using the storage encryption disk show-status command.

= Destroy a FIPS drive or SED

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

If you want to make data on a FIPS drive or SED permanently inaccessible and you do not need to reuse the drive, you can use the storage encryption disk destroy command to destroy the disk.

What you'll need

You must be a cluster administrator to perform this task.

About this task

When you destroy a FIPS drive or SED, the system sets the disk encryption key to an unknown random value and locks the drive irreversibly. Doing so renders the disk virtually unusable and the data on it permanently inaccessible. However, you can reset the disk to its factory-configured settings using the physical secure ID (PSID) printed on the disk's label. For more information, see [Returning a FIPS drive or SED to service when authentication keys are lost](#).

You should not destroy a FIPS drive or SED unless you have the Non-Returnable Disk Plus service (NRD Plus). Destroying a disk voids its warranty.

Steps

1. Migrate any data that needs to be preserved to an aggregate on another different disk.
2. Delete the aggregate on the FIPS drive or SED to be destroyed:

```
storage aggregate delete -aggregate aggregate_name
```

For complete command syntax, see the man page.

```
cluster1::> storage aggregate delete -aggregate aggr1
```

3. Identify the disk ID for the FIPS drive or SED to be destroyed:

```
storage encryption disk show
```

For complete command syntax, see the man page.

```
cluster1::> storage encryption disk show
Disk      Mode Data Key ID
-----
-----
0.0.0    data
F1CB30AFF1CB30B0010100000000000A68B167F92DD54196297159B5968923C
0.0.1    data
F1CB30AFF1CB30B0010100000000000A68B167F92DD54196297159B5968923C
1.10.2   data
F1CB30AFF1CB30B0010100000000000CF0EFD81EA9F6324EA97B369351C56AC
[...]
```

4. Destroy the disk:

```
storage encryption disk destroy -disk disk_id
```

For complete command syntax, see the man page.

You are prompted to enter a confirmation phrase before continuing. Enter the phrase exactly as shown on the screen.

```

cluster1::> storage encryption disk destroy -disk 1.10.2

Warning: This operation will cryptographically destroy 1 spare or
broken
          self-encrypting disks on 1 node.
          You cannot reuse destroyed disks unless you revert
          them to their original state using the PSID value.
          To continue, enter
          destroy disk
          :destroy disk

Info: Starting destroy on 1 disk.
      View the status of the operation by using the
      "storage encryption disk show-status" command.

```

= Emergency shredding of data on a FIPS drive or SED

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

In case of a security emergency, you can instantly prevent access to a FIPS drive or SED, even if power is not available to the storage system or the KMIP server.

What you'll need

- If you are using a KMIP server that has no available power, the KMIP server must be configured with an easily destroyed authentication item (for example, a smart card or USB drive).
- You must be a cluster administrator to perform this task.

Step

1. Perform emergency shredding of data on a FIPS drive or SED:

If...	Then...

Power is available to the storage system and you have time to take the storage system offline gracefully

a. If the storage system is configured as an HA pair, disable takeover.

b. Take all aggregates offline and delete them.

c. Set the privilege level to advanced:

```
set -privilege advanced
```

d. If the drive is in FIPS-compliance mode, set the FIPS authentication key ID for the node back to the default MSID:

```
storage encryption disk modify -disk * -fips  
-key-id 0x0
```

e. Halt the storage system.

f. Boot into maintenance mode.

g. Sanitize or destroy the disks:

- If you want to make the data on the disks inaccessible and still be able to reuse the disks, sanitize the disks:

```
disk encrypt sanitize -all
```

- If you want to make the data on the disks inaccessible and you do not need to save the disks, destroy the disks:

```
disk encrypt destroy disk_id1 disk_id2 ...
```

The `disk encrypt sanitize` and `disk encrypt destroy` commands are reserved for maintenance mode only. These commands must be run on each HA node, and are not available for broken disks.

h. Repeat these steps for the partner node.

This leaves the storage system in a permanently disabled state with all data erased. To use the system again, you must reconfigure it.

<p>Power is available to the storage system and you must shred the data immediately</p>	<ul style="list-style-type: none"> a. If you want to make the data on the disks inaccessible and still be able to reuse the disks, sanitize the disks: b. If the storage system is configured as an HA pair, disable takeover. c. Set the privilege level to advanced: <pre>set -privilege advanced</pre> d. If the drive is in FIPS-compliance mode, set the FIPS authentication key ID for the node back to the default MSID: <pre>storage encryption disk modify -disk * -fips-key-id 0x0</pre> e. Sanitize the disk: <pre>storage encryption disk sanitize -disk * -force-all-states true</pre> 	<ul style="list-style-type: none"> a. If you want to make the data on the disks inaccessible and you do not need to save the disks, destroy the disks: b. If the storage system is configured as an HA pair, disable takeover. c. Set the privilege level to advanced: <pre>set -privilege advanced</pre> d. Destroy the disks: <pre>storage encryption disk destroy -disk * -force-all-states true</pre>
<p>The storage system panics, leaving the system in a permanently disabled state with all data erased. To use the system again, you must reconfigure it.</p>		
<p>Power is available to the KMIP server but not to the storage system</p>	<ul style="list-style-type: none"> a. Log in to the KMIP server. b. Destroy all keys associated with the FIPS drives or SEDs that contain the data you want to prevent access to. This prevents access to disk encryption keys by the storage system. 	
<p>Power is not available to the KMIP server or the storage system</p>	<p>Destroy the authentication item for the KMIP server (for example, the smart card). This prevents access to disk encryption keys by the storage system.</p>	

For complete command syntax, see the man pages.

= Return a FIPS drive or SED to service when authentication keys are lost
:icons: font

```
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/
:hardbreaks-option:
```

The system treats a FIPS drive or SED as broken if you lose the authentication keys for it permanently and cannot retrieve them from the KMIP server. Although you cannot access or recover the data on the disk, you can take steps to make the SED's unused space available again for data.

What you'll need

You must be a cluster administrator to perform this task.

About this task

You should use this process only if you are certain that the authentication keys for the FIPS drive or SED are permanently lost and that you cannot recover them.

Steps

1. Return a FIPS drive or SED to service:

If the SEDs are...	Use these steps...
Not in FIPS-compliance mode, or in FIPS-compliance mode and the FIPS key is available	<ol style="list-style-type: none">a. Set the privilege level to advanced: <code>set -privilege advanced</code>b. Reset the FIPS key to the default manufacture secure ID 0x0: <code>storage encryption disk modify -fips-key-id 0x0 -disk disk_id</code>c. Verify the operation succeeded: <code>storage encryption disk show-status</code> If the operation failed, use the PSID process in this topic.d. Sanitize the broken disk: <code>storage encryption disk sanitize -disk disk_id</code> Verify the operation succeeded with the command <code>storage encryption disk show-status</code> before proceeding to the next step.e. Unfail the sanitized disk: <code>storage disk unfail -spare true -disk disk_id</code>f. Check whether the disk has an owner: <code>storage disk show -disk disk_id</code>g. If the disk does not have an owner, assign one, then unfail the disk again: <code>storage disk assign -owner node -disk disk_id</code> <code>storage disk unfail -spare true -disk disk_id</code>h. Verify that the disk is now a spare and ready to be reused in an aggregate: <code>storage disk show -disk disk_id</code>

<p>In FIPS-compliance mode, the FIPS key is not available, and the SEDs have a PSID printed on the label</p>	<ol style="list-style-type: none"> a. Obtain the PSID of the disk from the disk label. b. Set the privilege level to advanced: <pre>set -privilege advanced</pre> c. Reset the disk to its factory-configured settings: <pre>storage encryption disk revert-to-original-state -disk disk_id -psid disk_physical_secure_id</pre> <p>Verify the operation succeeded with the command <code>storage encryption disk show-status</code> before proceeding to the next step.</p> d. Unfail the sanitized disk: <pre>storage disk unfail -spare true -disk disk_id</pre> e. Check whether the disk has an owner: <pre>storage disk show -disk disk_id</pre> f. If the disk does not have an owner, assign one, then unfail the disk again: <pre>storage disk assign -owner node -disk disk_id</pre> <pre>storage disk unfail -spare true -disk disk_id</pre> g. Verify that the disk is now a spare and ready to be reused in an aggregate: <pre>storage disk show -disk disk_id</pre>
--	---

For complete command syntax, see the man pages.

= Return a FIPS drive or SED to unprotected mode

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..../media/

A FIPS drive or SED is protected from unauthorized access only if the authentication key ID for the node is set to a value other than the default. You can return a FIPS drive or SED to unprotected mode by using the `storage encryption disk modify` command to set the key ID to the default.

If an HA pair is using encrypting SAS or NVMe drives (SED, NSE, FIPS), you must follow this process for all drives within the HA pair prior to initializing the system (boot options 4 or 9). Failure to do this may result in future data loss if the drives are repurposed.

What you'll need

You must be a cluster administrator to perform this task.

Steps

1. Set the privilege level to advanced:

```
set -privilege advanced
```

2. If a FIPS drive is running in FIPS-compliance mode, set the FIPS authentication key ID for the node back to the default MSID 0x0:

```
storage encryption disk modify -disk disk_id -fips-key-id 0x0
```

You can use the security key-manager query command to view key IDs.

```
cluster1::> storage encryption disk modify -disk 2.10.11 -fips-key  
-id 0x0
```

Info: Starting modify on 14 disks.

View the status of the operation by using the
storage encryption disk show-status command.

Confirm the operation succeeded with the command:

```
storage encryption disk show-status
```

Repeat the show-status command until the numbers are the same. The operation is complete when the numbers in “disks begun” and “disks done” are the same.

```
cluster1:: storage encryption disk show-status
```

Disks	FIPS Disks	Latest Support	Start Request	Timestamp	Execution Time (sec)	Disks Begun
Done	Successful	-----	-----	-----	-----	-----
cluster1	true	modify	5	1/18/2022 15:29:38	3	14
1	entry was displayed.					

3. Set the data authentication key ID for the node back to the default MSID 0x0:

```
storage encryption disk modify -disk disk_id -data-key-id 0x0
```

The value of -data-key-id should be set to 0x0 whether you are returning a SAS or NVMe drive to unprotected mode.

You can use the security key-manager query command to view key IDs.

```
cluster1::> storage encryption disk modify -disk 2.10.11 -data-key  
-id 0x0
```

Info: Starting modify on 14 disks.

View the status of the operation by using the
storage encryption disk show-status command.

Confirm the operation succeeded with the command:

```
storage encryption disk show-status
```

Repeat the show-status command until the numbers are the same. The operation is complete when the numbers in “disks begun” and “disks done” are the same.

= Remove an external key manager connection

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

You can disconnect a KMIP server from a node when you no longer need the server. For example, you might disconnect a KMIP server when you are transitioning to volume encryption.

What you'll need

You must be a cluster or SVM administrator to perform this task.

About this task

When you disconnect a KMIP server from one node in an HA pair, the system automatically disconnects the server from all cluster nodes.

If you plan to continue using external key management after disconnecting a KMIP server, make sure another KMIP server is available to serve authentication keys.

Step

1. Disconnect a KMIP server from the current node:

For this ONTAP version...	Use this command...
ONTAP 9.6 and later	<code>security key-manager external remove-servers -vserver SVM -key-servers host_name IP_address:port,...</code>
ONTAP 9.5 and earlier	<code>security key-manager delete -address key_management_server_ipaddress</code>

For complete command syntax, see the man pages.

The following ONTAP 9.6 command disables the connections to two external key management servers for `cluster1`, the first named `ks1`, listening on the default port 5696, the second with the IP address 10.0.0.20, listening on port 24482:

```
cluster1::> security key-manager external remove-servers -vserver
cluster-1 -key-servers ks1,10.0.0.20:24482
```

= Modify external key management server properties

```
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source./encryption-at-rest../media/
```

Beginning with ONTAP 9.6, you can use the `security key-manager external modify-server` command to change the I/O timeout and user name of an external key management server.

What you'll need

- You must be a cluster or SVM administrator to perform this task.
- Advanced privileges are required for this task.

Steps

1. On the storage system, change to advanced privilege level:

```
set -privilege advanced
```

2. Modify external key manager server properties for the cluster:

```
security key-manager external modify-server -vserver admin_SVM -key-server
host_name|IP_address:port,... -timeout 1...60 -username user_name
```

The timeout value is expressed in seconds. If you modify the user name, you are prompted to enter a new password. If you run the command at the cluster login prompt, `admin_SVM` defaults to the admin SVM of the current cluster. You must be the cluster administrator to modify external key manager server properties.

The following command changes the timeout value to 45 seconds for the `cluster1` external key management server listening on the default port 5696:

```
cluster1::> security key-manager external modify-server -vserver
cluster1 -key-server ks1.local -timeout 45
```

3. Modify external key manager server properties for an SVM (NVE only):

```
security key-manager external modify-server -vserver SVM -key-server
host_name|IP_address:port,... -timeout 1...60 -username user_name
```

The timeout value is expressed in seconds. If you modify the user name, you are prompted to enter a new password. If you run the command at the SVM login prompt, `SVM` defaults to the current SVM. You must be the cluster or SVM administrator to modify external key manager server properties.

The following command changes the username and password of the `svm1` external key management server listening on the default port 5696:

```
svml::> security key-manager external modify-server -vserver svml1  
-key-server ks1.local -username svmluser  
Enter the password:  
Reenter the password:
```

4. Repeat the last step for any additional SVMs.

= Transition to external key management from onboard key management

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

If you want to switch to external key management from onboard key management, you must delete the onboard key management configuration before you can enable external key management.

What you'll need

- For hardware-based encryption, you must reset the data keys of all FIPS drives or SEDs to the default value.

[Returning a FIPS drive or SED to unprotected mode](#)

- For software-based encryption, you must unencrypt all volumes.

[Unencrypting volume data](#)

- You must be a cluster administrator to perform this task.

Step

1. Delete the onboard key management configuration for a cluster:

For this ONTAP version...	Use this command...
ONTAP 9.6 and later	security key-manager onboard disable -vserver SVM
ONTAP 9.5 and earlier	security key-manager delete-key-database

For complete command syntax, see the [xref:./encryption-at-rest/ONTAP manual pages](#).

= Transition to onboard key management from external key management

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

If you want to switch to onboard key management from external key management, you must delete the external key management configuration before you can enable onboard key management.

Before you begin

- For hardware-based encryption, you must reset the data keys of all FIPS drives or SEDs to the default value.

[Returning a FIPS drive or SED to unprotected mode](#)

- You must have deleted all external key manager connections.

[Deleting an external key manager connection](#)

- You must be a cluster administrator to perform this task.

== Procedure

ONTAP 9.6 and later

1. Change to the advanced privilege level:

```
set -privilege advanced
```

2. Use the command:

```
security key-manager external disable -vserver admin_SVM
```

ONTAP 9.5 and earlier

Use the command:

```
security key-manager delete-kmip-config
```

= What happens when key management servers are not reachable during the boot process

:icons: font

:relative_path: ./encryption-at-rest/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./encryption-at-rest/..media/

ONTAP takes certain precautions to avoid undesired behavior in the event that a storage system configured for NSE cannot reach any of the specified key management servers during the boot process.

If the storage system is configured for NSE, the SEDs are rekeyed and locked, and the SEDs are powered on, the storage system must retrieve the required authentication keys from the key management servers to authenticate itself to the SEDs before it can access the data.

The storage system attempts to contact the specified key management servers for up to three hours. If the storage system cannot reach any of them after that time, the boot process stops and the storage system halts.

If the storage system successfully contacts any specified key management server, it then attempts to establish an SSL connection for up to 15 minutes. If the storage system cannot establish an SSL connection with any specified key management server, the boot process stops and the storage system halts.

While the storage system attempts to contact and connect to key management servers, it displays detailed information about the failed contact attempts at the CLI. You can interrupt the contact attempts at

any time by pressing Ctrl-C.

As a security measure, SEDs allow only a limited number of unauthorized access attempts, after which they disable access to the existing data. If the storage system cannot contact any specified key management servers to obtain the proper authentication keys, it can only attempt to authenticate with the default key which leads to a failed attempt and a panic. If the storage system is configured to automatically reboot in case of a panic, it enters a boot loop which results in continuous failed authentication attempts on the SEDs.

Halting the storage system in these scenarios is by design to prevent the storage system from entering a boot loop and possible unintended data loss as a result of the SEDs locked permanently due to exceeding the safety limit of a certain number of consecutive failed authentication attempts. The limit and the type of lockout protection depends on the manufacturing specifications and type of SED:

SED type	Number of consecutive failed authentication attempts resulting in lockout	Lockout protection type when safety limit is reached
HDD	1024	Permanent. Data cannot be recovered, even when the proper authentication key becomes available again.
X440_PHM2800MCTO 800GB NSE SSDs with firmware revisions NA00 or NA01	5	Temporary. Lockout is only in effect until disk is power-cycled.
X577_PHM2800MCTO 800GB NSE SSDs with firmware revisions NA00 or NA01	5	Temporary. Lockout is only in effect until disk is power-cycled.
X440_PHM2800MCTO 800GB NSE SSDs with higher firmware revisions	1024	Permanent. Data cannot be recovered, even when the proper authentication key becomes available again.
X577_PHM2800MCTO 800GB NSE SSDs with higher firmware revisions	1024	Permanent. Data cannot be recovered, even when the proper authentication key becomes available again.
All other SSD models	1024	Permanent. Data cannot be recovered, even when the proper authentication key becomes available again.

For all SED types, a successful authentication resets the try count to zero.

If you encounter this scenario where the storage system is halted due to failure to reach any specified key management servers, you must first identify and correct the cause for the communication failure before you attempt to continue booting the storage system.

= Disable encryption by default with ONTAP 9.7 and later
:icons: font
:relative_path: ./encryption-at-rest/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/./media/

Beginning with ONTAP 9.7, aggregate and volume encryption is enabled by default if you have a volume encryption (VE) license and use an onboard or external key manager. You can disable encryption by default if required.

What you'll need

You must be a cluster administrator to perform this task, or an SVM administrator to whom the cluster administrator has delegated authority.

Step

1. To disable encryption by default in ONTAP 9.7 or later, run the following command:

```
options -option-name encryption.data_at_rest_encryption.disable_by_default  
-vserver (vservername or * for all) -option-value on
```

For complete command syntax, see the man page for the command.

The topics in this section show you how to configure and manage data protection with System Manager in ONTAP 9.7 and later releases.

If you are using the classic System Manager (available only in ONTAP 9.7 and earlier), see this topic:

- [Managing data protection](#)

Protect your data by creating and managing Snapshot copies, mirrors, vaults, and mirror-and-vault relationships.

SnapMirror is disaster recovery technology, designed for failover from primary storage to secondary storage at a geographically remote site. As its name implies, SnapMirror creates a replica, or mirror, of your working data in secondary storage from which you can continue to serve data in the event of a catastrophe at the primary site.

A **vault** is designed for disk-to-disk Snapshot copy replication for standards compliance and other governance-related purposes. In contrast to a SnapMirror relationship, in which the destination usually contains only the Snapshot copies currently in the source volume, a vault destination typically retains point-in-time Snapshot copies created over a much longer period.

Beginning with ONTAP 9.10.1, you can create data protection relationships between S3 buckets using S3 SnapMirror. Destination buckets can be on local or remote ONTAP systems, or on non-ONTAP systems such as StorageGRID and AWS. For more information, see [S3 SnapMirror overview](#).

= Create custom data protection policies

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

You can create custom data protection policies with System Manager when the existing default protection policies are not appropriate for your needs.

Create custom protection policies on both the source and destination cluster.

Steps

1. Click **Protection > Local Policy Settings**.
2. Under **Protection Policies**, click .
3. In the **Protection Policies** pane, click  **Add**.
4. Complete the required fields.
5. Click **Save**.
6. Repeat these steps on the other cluster.

= Configure Snapshot copies

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

You can create Snapshot copy policies to specify the maximum number of Snapshot copies that are automatically created and how frequently they are created. The policy specifies when to create Snapshot copies, how many copies to retain, and how to name them.

This procedure creates a Snapshot copy policy on the local cluster only.

Steps

1. Click **Protection > Overview > Local Policy Settings**.
2. Under **Snapshot Policies**, click , and then click  **Add**.

3. Type the policy name, select the policy scope, and under **Schedules**, click  **Add** to enter the schedule details.

= Calculate reclaimable space before deleting Snapshot copies

:icons: font

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Beginning with ONTAP 9.10.1, you can use System Manager to select Snapshot copies you want to delete and calculate the reclaimable space before you delete them.

Steps

1. Click **Storage > Volumes**.
2. Select the volume from which you want to delete Snapshot copies.
3. Click **Snapshot Copies**.
4. Select one or more Snapshot copies.
5. Click **Calculate Reclaimable Space**.

= Enable or disable client access to Snapshot copy directory

:icons: font

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Beginning with ONTAP 9.10.1, you can use System Manager to enable or disable client systems to access to a Snapshot copy directory on a volume. Enabling access makes the Snapshot copy directory visible to clients and allows Windows clients to map a drive to the Snapshot copies directory to view and access its contents.

You can enable or disable access to a volume's Snapshot copy directory by editing the volume settings or by editing the volume's share settings.

== Enable or disable client access to Snapshot copy directory by editing a volume

The Snapshot copy directory on a volume is accessible to clients by default.

Steps

1. Click **Storage > Volumes**.
2. Select the volume containing the Snapshot copies directory you want to either show or hide.
3. Click  and select **Edit**.
4. In the **Snapshot Copies (Local) Settings** section, select or deselect **Show the Snapshot copies directory to clients**.
5. Click **Save**.

== Enable or disable client access to Snapshot copy directory by editing a share

The Snapshot copy directory on a volume is accessible to clients by default.

Steps

1. Click **Storage > Shares**.
2. Select the volume containing the Snapshot copies directory you want to either show or hide.
3. Click  and select **Edit**.
4. In the **Share Properties** section, select or deselect **Allow clients to access Snapshot copies directory**.
5. Click **Save**.

= Recover from Snapshot copies

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

You can recover a volume to an earlier point in time by restoring from a Snapshot copy.

This procedure restores a volume from a Snapshot copy.

Steps

1. Click **Storage** and select a volume.
2. Under **Snapshot Copies**, click  next to the Snapshot copy you want to restore, and select **Restore**.

= Prepare for mirroring and vaulting

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

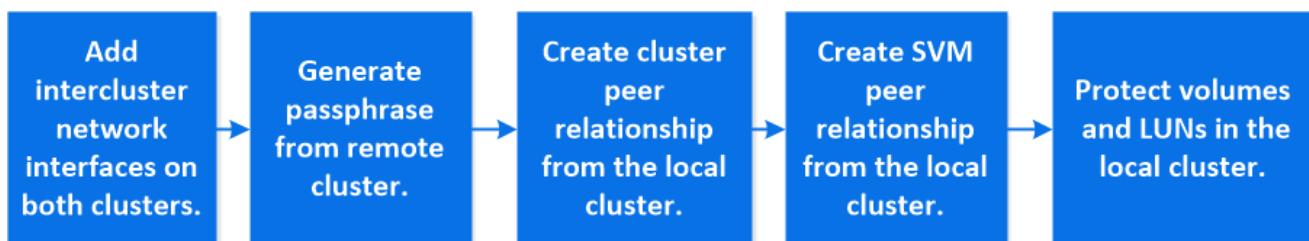

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

You can protect your data by replicating it to a remote cluster for data backup and disaster recovery purposes.

Several default protection policies are available. You must have created your protection policies if you want to use custom policies.

Steps

1. In the local cluster, click **Protection > Overview**.

2. Expand **Intercluster Settings**. Click **Add Network Interfaces** and add intercluster network interfaces for the cluster.

Repeat this step on the remote cluster.

3. In the remote cluster, click **Protection > Overview**. Click **⋮** in the Cluster Peers section and click **Generate Passphrase**.
4. Copy the generated passphrase and paste it in the local cluster.
5. In the local cluster, under Cluster Peers, click **Peer Clusters** and peer the local and remote clusters.
6. Optionally, under Storage VM Peers, click **⋮** and then **Peer Storage VMs** to peer the storage VMs.
7. Click **Protect Volumes** to protect your volumes. To protect your LUNs, click **Storage > LUNs**, select a LUN to protect, and then click  **Protect**.

Select the protection policy based on the type of data protection you need.

8. To verify the volumes and LUNs are successfully protected from the local cluster, click **Storage > Volumes** or **Storage > LUNs** and, expand the volume/LUN view.

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume disaster recovery preparation overview
The ONTAP command line interface	Create a cluster peer relationship (ONTAP 9.3 and later)

= Configure mirrors and vaults

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/.media/

Create a mirror and vault of a volume to protect data in case of a disaster and to have multiple archived versions of data to which you can roll back. Only the combined mirror-and-vault policy is supported. You cannot specify separate mirror and vault policies.

This procedure creates a mirror-and-vault policy on a remote cluster. The source cluster and destination cluster use intercluster network interfaces for exchanging data. The procedure assumes the [intercluster network interfaces are created and the clusters containing the volumes are peered](#) (paired). You can also peer storage VMs for data protection; however, if storage VMs are not peered, but permissions are enabled, storage VMs are automatically peered when the protection relationship is created.

Steps

1. Select the volume or LUN to protect: click **Storage > Volumes** or **Storage > LUNs**, and then click the desired volume or LUN name.
2. Click  **Protect**.
3. Select the destination cluster and storage VM.
4. The asynchronous policy is selected by default. To select a synchronous policy, click **More Options**.
5. Click **Protect**.
6. Click the **SnapMirror (Local or Remote)** tab for the selected volume or LUN to verify that protection is set up correctly.

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume backup using SnapVault overview
The ONTAP command line interface	Create a replication relationship

= Configure storage VM disaster recovery

```
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ../
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

Using System Manager, you can create an storage VM disaster recovery (storage VM DR) relationship to replicate one storage VM configuration to another. In the event of a disaster at the primary site, you can quickly activate the destination storage VM.

Complete this procedure from the destination. If you need to create a new protection policy, for instance, when your source storage VM has SMB configured, you should use System Manager to create the policy and select the **Copy source storage VM configuration** option in the **Add Protection Policy** window. For details see [Create custom data protection policies](#).

Steps

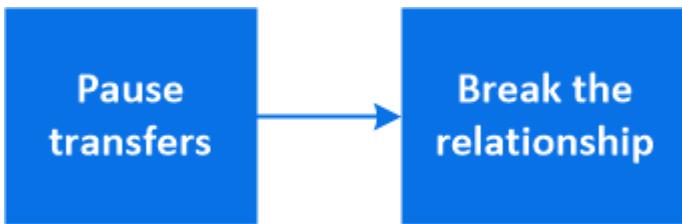

1. On the destination cluster, click **Protection > Relationships**.
2. Under **Relationships**, click Protect and choose **Storage VMs (DR)**.
3. Select a protection policy. If you created a custom protection policy, select it, then choose the source cluster and storage VM you want to replicate. You can also create a new destination storage VM by entering a new storage VM name.
4. Click **Save**.

= Serve data from a SnapMirror destination

```
:toc: macro
:toclevels: 1
:hardbreaks:
```

```
:icons: font
:linkatrs:
:relative_path: ./media/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

To serve data from a mirror destination when a source becomes unavailable, stop scheduled transfers to the destination, and then break the SnapMirror relationship to make the destination writable.

Steps

1. Select the desired protection relationship: click **Protection > Relationships**, and then click the desired volume name.
2. Click .
3. Stop scheduled transfers : click **Pause**.
4. Make the destination writable: click **Break**.
5. Go to the main **Relationships** page to verify that the relationship state displays as "broken off".

Next steps:

When the disabled source volume is available again, you should resynchronize the relationship to copy the current data to the original source volume. This process replaces the data on the original source volume.

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume disaster recovery overview
The ONTAP command line interface	Activate the destination volume

= Resynchronize a protection relationship

```
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrs:
:relative_path: ./media/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

When your original source volume is available again after a disaster, you can resynchronize data from the destination volume and reestablish the protection relationship.

This procedure replaces the data in the original source volume in an asynchronous relationship so that you can start serving data from the original source volume again and resume the original protection relationship.

Steps

1. Click **Protection > Relationships** and then click the broken off relationship you want to resynchronize.
2. Click  and then select **Resync**.
3. Under **Relationships**, monitor the resynchronization progress by checking the relationship state. The state changes to "Mirrored" when resynchronization is complete.

= Restore a volume from an earlier Snapshot copy

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

When data in a volume is lost or corrupted, you can roll back your data by restoring from an earlier Snapshot copy.

This procedure replaces the current data on the source volume with data from an earlier Snapshot copy version. You should perform this task on the destination cluster.

Steps

1. Click **Protection > Relationships**, and then click the source volume name.
2. Click  and then select **Restore**.
3. Under **Source**, the source volume is selected by default. Click **Other Volume** if you want to choose a volume other than the source.
4. Under **Destination**, choose the Snapshot copy you want to restore.
5. If your source and destination are located on different clusters, on the remote cluster, click **Protection > Relationships** to monitor the restore progress.

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume restore using SnapVault overview
The ONTAP command line interface	Restore the contents of a volume from a SnapMirror destination

= Recover from Snapshot copies

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

```
:relative_path: ./  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

You can recover a volume to an earlier point in time by restoring from a Snapshot copy.

This procedure restores a volume from a Snapshot copy.

Steps

1. Click **Storage** and select a volume.
2. Under **Snapshot Copies**, click  next to the Snapshot copy you want to restore, and select **Restore**.

= Restore to a new volume

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

Beginning with ONTAP 9.8, you can use System Manager to restore backed up data on the destination volume to a volume other than the original source.

When you restore to a different volume, you can select an existing volume, or you can create a new volume.

Steps

1. Select the desired protection relationship: click **Protection > Relationships**.
2. Click  and click **Restore**.
3. Under **Relationships**, monitor the restore progress by viewing **Transfer Status** for the relationship.

= Reverse Resynchronizing a Protection Relationship

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

Beginning with ONTAP 9.8, you can use System Manager to perform a reverse resynchronization operation to delete an existing protection relationship and reverse the functions of the source and destination volumes. Then you use the destination volume to serve data while you repair or replace the source, update the source, and reestablish the original configuration of the systems.

When you perform a reverse resynch operation, any data on the source volume that is newer than the data in the common Snapshot copy is deleted.

Steps

1. Select the desired protection relationship: click **Protection > Relationships**.
2. Click  and click **Reverse Resync**.
3. Under **Relationships**, monitor the reverse resynchronization progress by viewing **Transfer Status** for the relationship.

= Reactivate a source storage VM

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

Beginning with ONTAP 9.8, you can use System Manager to reactivate a source storage VM after a disaster. Reactivating the source storage VM stops the destination storage VM, and it reenables replication from the source to the destination.

Steps

1. Select the desired protection relationship: click **Protection > Relationships**.
2. Click  and click **Reactivate Source Storage VM**.
3. Under **Relationships**, monitor the source reactivation progress by viewing **Transfer Status** for the protection relationship.

= Resynchronize a destination storage VM

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

Beginning with ONTAP 9.8, you can use System Manager to resynchronize the data and configuration details from the source storage VM to the destination storage VM in a broken protection relationship and reestablish the relationship.

You perform the resync operation only from the destination of the original relationship. The resync deletes any data in the destination storage VM that is newer than the data in the source storage VM.

Steps

1. Select the desired protection relationship: click **Protection > Relationships**.
2. Click  and click **Resync**.
3. Under **Relationships**, monitor the resynchronization progress by viewing **Transfer Status** for the relationship.

= Back up data to the cloud using SnapMirror

:toc: macro

:toplevels: 1

:hardbreaks:

```
:icons: font
:linkatrs:
:relative_path: ../
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

Beginning with ONTAP 9.9.1, you can back up your data to the cloud and to restore your data from cloud storage to a different volume by using System Manager. You can use either StorageGRID or ONTAP S3 as your cloud object store.

Before using the SnapMirror Cloud feature, you should generate a SnapMirror Cloud API license key on the NetApp Support Site: [Generate SnapMirror Cloud API license key](#)

== Add a cloud object store

Before you configure SnapMirror Cloud backups, you need to add a StorageGRID or ONTAP S3 cloud object store.

Steps

1. Click **Protection > Overview > Cloud Object Stores**.
2. Click  **Add**.

== Back up using the default policy

You can quickly configure a SnapMirror Cloud backup for an existing volume using the default cloud protection policy, DailyBackup.

Steps

1. Click **Protection > Overview** and select **Back Up Volumes to Cloud**.
2. If this is your first time backing up to the cloud, enter your SnapMirror Cloud API license key in the license field as indicated.
3. Click **Authenticate and Continue**.
4. Select a source volume.
5. Select a cloud object store.
6. Click **Save**.

== Create a custom cloud backup policy

If you do not want to use the default DailyBackup cloud policy for your SnapMirror Cloud backups, you can create your own policy.

Steps

1. Click **Protection > Overview > Local Policy Settings** and select **Protection Policies**.
2. Click **Add** and enter the new policy details.
3. In the **Policy Type** section, select **Back up to Cloud** to indicate that you are creating a cloud policy.
4. Click **Save**.

== Create a backup from the **Volumes** page

You can use the System Manager **Volumes** page to when you want to select and create cloud backups for multiple volumes at one time or when you want to use a custom protection policy.

Steps

1. Click **Storage > Volumes**.
2. Select the volumes you want to back up to the cloud, and click **Protect**.
3. In the **Protect Volume** window, click **More Options**.
4. Select a policy.

You can select the default policy, DailyBackup, or a custom cloud policy you created.

5. Select a cloud object store.
6. Click **Save**.

== Restore from the cloud

You can use System Manager to restore backed up data from cloud storage to a different volume on the source cluster.

Steps

1. Click **Storage > Volumes**.
2. Select the **Back Up to Cloud** tab.
3. Click  next to the source volume you want to restore, and select **Restore**.
4. Under **Source**, select a storage VM and then enter the name of the volume to which you want the data restored.
5. Under **Destination**, select the Snapshot copy you want to restore.
6. Click **Save**.

== Delete a SnapMirror Cloud relationship

You can use System Manager to delete a cloud relationship.

Steps

1. Click **Storage > Volumes** and select the volume you want to delete.
2. Click  next to the source volume and select **Delete**.
3. Select **Delete the cloud object store endpoint (optional)** if you want to delete the cloud object store endpoint.
4. Click **Delete**.

== Remove a cloud object store

You can use System Manager to remove a cloud object store if it is not part of a cloud backup relationship. When a cloud object store is part of a cloud backup relationship, it cannot be deleted.

Steps

1. Click **Protection > Overview > Cloud Object Stores**.
2. Select the object store you want to delete, click  and select **Delete**.

= Back up data using Cloud Backup

:toc: macro

:toclevels: 1

```
:hardbreaks:  
:icons: font  
:linkatrrs:  
:relative_path: ./  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

Beginning with ONTAP 9.9.1, you can use System Manager to back up data in the cloud using Cloud Backup.

Cloud Backup supports FlexVol read-write volumes and data-protection (DP) volumes. FlexGroup volumes and SnapLock volumes are not supported.

Before you begin

You should perform the following procedures to establish an account in Cloud Manager. For the service account, you need to create the role as "Account Admin". (Other service account roles do not have the required privileges needed to establish a connection from System Manager.)

1. [Create an account in Cloud Manager](#).
2. [Create a connector in Cloud Manager](#) with one of the following cloud providers:
 - Microsoft Azure
 - Amazon Web Services (AWS)
 - Google Cloud Platform (GCP)
 - StorageGrid (ONTAP 9.10.1)

Beginning with ONTAP 9.10.1, you can select StorageGrid as a cloud backup provider, but only if Cloud Manager is deployed on premises. The Cloud Manager connector must be installed on premises and available through the Cloud Manager software-as-a-service (SaaS) application.

3. [Subscribe to Cloud Backup Service in Cloud Manager](#) (requires the appropriate license).
4. [Generate an access key and a secret key using Cloud Manager](#).

== Register the cluster with Cloud Manager

You can register the cluster with Cloud Manager by using either Cloud Manager or System Manager.

Steps

1. In System Manager, go to **Protection Overview**.
2. Under **Cloud Backup Service**, provide the following details:
 - Client ID
 - Client secret key
3. Select **Register and Continue**.

== Enable Cloud Backup

After the cluster is registered with Cloud Manager, you need to enable the Cloud Backup and initiate the first backup to the cloud.

Steps

1. In System Manager, click **Protection > Overview**, then scroll to the **Cloud Backup Service** section.
2. Enter the **Client ID** and **Client Secret**.

Beginning with ONTAP 9.10.1, you can learn about the cost of using the cloud by clicking **Learn more about the cost of using the cloud**.

3. Click **Connect and Enable Cloud Backup Service**.

4. On the **Enable Cloud Backup Service** page, provide the following details, depending on the provider you selected.

For this cloud provider...	Enter the following data...
Azure	<ul style="list-style-type: none">• Azure Subscription ID• Region• Resource group name (existing or new)
AWS	<ul style="list-style-type: none">• AWS Account ID• Access key• Secret key• Region
Google Cloud Project (GCP)	<ul style="list-style-type: none">• Google Cloud Project name• Google Cloud Access key• Google Cloud Secret key• Region
StorageGrid (ONTAP 9.10.1 and later, and only for on-premises deployment of Cloud Manager)	<ul style="list-style-type: none">• Server• SG Access Key• SG Secret Key

5. Select a **Protection policy**:

- **Existing policy:** Choose an existing policy.
- **New Policy:** Specify a name and set up a transfer schedule.

Beginning with ONTAP 9.10.1, you can specify whether you want to enable archiving with Azure or AWS.

If you enable archiving for a volume with Azure or AWS, you cannot disable the archiving.

If you enable archiving for Azure or AWS, specify the following:

- The number of days after which the volume is archived.

- The number of backups to retain in the archive. Specify “0” (zero) to archive up to the latest backup.
- For AWS, select the archive storage class.

6. Select the volumes you want to back up.

7. Select **Save**.

== Edit the protection policy used for Cloud Backup

You can change which protection policy is used with Cloud Backup.

Steps

1. In System Manager, click **Protection > Overview**, then scroll to the **Cloud Backup Service** section.

2. Click , then **Edit**.

3. Select a **Protection policy**:

- **Existing policy**: Choose an existing policy.
- **New Policy**: Specify a name and set up a transfer schedule.

Beginning with ONTAP 9.10.1, you can specify whether you want to enable archiving with Azure or AWS.

If you enable archiving for a volume with Azure or AWS, you cannot disable the archiving.

If you enable archiving for Azure or AWS, specify the following:

- The number of days after which the volume is archived.
- The number of backups to retain in the archive. Specify “0” (zero) to archive up to the latest backup.
- For AWS, select the archive storage class.

4. Select **Save**.

== Protect new volumes or LUNs on the cloud

When you create a new volume or LUN, you can establish a SnapMirror protection relationship that enables backing up to the cloud for the volume or LUN.

Before you begin

- You should have a SnapMirror license.
- Intercluster LIFs should be configured.
- NTP should be configured.
- Cluster must be running ONTAP 9.9.1.

About this task

You cannot protect new volumes or LUNs on the cloud for the following cluster configurations:

- The cluster cannot be in a MetroCluster environment.

- SVM-DR is not supported.
- FlexGroups cannot be backed up using Cloud Backup.

Steps

1. When provisioning a volume or LUN, on the **Protection** page in System Manager, select the checkbox labeled **Enable SnapMirror (Local or Remote)**.
2. Select the Cloud Backup policy type.
3. If the Cloud Backup is not enabled, select **Enable Cloud Backup Service**.

== Protect existing volumes or LUNs on the cloud

You can establish a SnapMirror protection relationship for existing volumes and LUNs.

Steps

1. Select an existing volume or LUN, and click **Protect**.
2. On the **Protect Volumes** page, specify **Backup using Cloud Backup Service** for the protection policy.
3. Click **Protect**.
4. On the **Protection** page, select the checkbox labeled **Enable SnapMirror (Local or Remote)**.
5. Select **Enable Cloud Backup Service**.

== Restore data from backup files

You can perform backup management operations, such as restoring data, updating relationships, and deleting relationships, only when using the Cloud Manager interface. Refer to [Restoring data from backup files](#) for more information.

= Cluster and SVM peering with the CLI

= Cluster and SVM peering overview with the CLI

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can create peer relationships between source and destination clusters and between source and destination storage virtual machines (SVMs). You must create peer relationships between these entities before you can replicate Snapshot copies using SnapMirror.

ONTAP 9.3 offers enhancements that simplify the way you configure peer relationships between clusters and SVMs. The cluster and SVMs peering procedures are available for all ONTAP 9 versions. You should use the appropriate procedure for your version of ONTAP.

You perform the procedures using the command-line interface (CLI), not System Manager or an automated scripting tool.

= Prepare for cluster and SVM peering

= Peering basics

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./encryption-at-rest/..media/

You must create *peer relationships* between source and destination clusters and between source and destination SVMs before you can replicate Snapshot copies using SnapMirror. A peer relationship defines network connections that enable clusters and SVMs to exchange data securely.

Clusters and SVMs in peer relationships communicate over the intercluster network using *intercluster logical interfaces (LIFs)*. An intercluster LIF is a LIF that supports the "intercluster-core" network interface service and is typically created using the "default-intercluster" network interface service policy. You must create intercluster LIFs on every node in the clusters being peered.

Intercluster LIFs use routes that belong to the system SVM to which they are assigned. ONTAP automatically creates a system SVM for cluster-level communications within an IPspace.

Fan-out and cascade topologies are both supported. In a cascade topology, you need only create intercluster networks between the primary and secondary clusters and between the secondary and tertiary clusters. You need not create an intercluster network between the primary and the tertiary cluster.

It is possible (but not advisable) for an administrator to remove the intercluster-core service from the default-intercluster service policy. If this occurs, LIFs created using "default-intercluster" will not actually be intercluster LIFs. To confirm that the default-intercluster service policy contains the intercluster-core service, use the following command:

```
network interface service-policy show -policy default-intercluster
```

= Prerequisites for cluster peering

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/./encryption-at-rest/..media/

Before you set up cluster peering, you should confirm that the connectivity, port, IP address, subnet, firewall, and cluster-naming requirements are met.

== Connectivity requirements

Every intercluster LIF on the local cluster must be able to communicate with every intercluster LIF on the remote cluster.

Although it is not required, it is typically simpler to configure the IP addresses used for intercluster LIFs in the same subnet. The IP addresses can reside in the same subnet as data LIFs, or in a different subnet. The subnet used in each cluster must meet the following requirements:

- The subnet must belong to the broadcast domain that contains the ports that are used for intercluster communication.
- The subnet must have enough IP addresses available to allocate to one intercluster LIF per node.

For example, in a four-node cluster, the subnet used for intercluster communication must have four available IP addresses.

Each node must have an intercluster LIF with an IP address on the intercluster network.

Intercluster LIFs can have an IPv4 address or an IPv6 address.

ONTAP 9 enables you to migrate your peering networks from IPv4 to IPv6 by optionally allowing both protocols to be present simultaneously on the intercluster LIFs. In earlier releases, all intercluster relationships for an entire cluster were either IPv4 or IPv6. This meant that changing protocols was a potentially disruptive event.

== Port requirements

You can use dedicated ports for intercluster communication, or share ports used by the data network. Ports must meet the following requirements:

- All ports that are used to communicate with a given remote cluster must be in the same IPspace.
You can use multiple IPspaces to peer with multiple clusters. Pair-wise full-mesh connectivity is required only within an IPspace.
- The broadcast domain that is used for intercluster communication must include at least two ports per node so that intercluster communication can fail over from one port to another port.
Ports added to a broadcast domain can be physical network ports, VLANs, or interface groups (ifgrps).
- All ports must be cabled.
- All ports must be in a healthy state.
- The MTU settings of the ports must be consistent.

== Firewall requirements

Firewalls and the intercluster firewall policy must allow the following protocols:

- ICMP service
- TCP to the IP addresses of all the intercluster LIFs over the ports 10000, 11104, and 11105
- Bidirectional HTTPS between the intercluster LIFs

Although HTTPS is not required when you set up cluster peering using the CLI, HTTPS is required later if you use System Manager to configure data protection.

The default intercluster firewall policy allows access through the HTTPS protocol and from all IP addresses (0.0.0.0/0). You can modify or replace the policy if necessary.

== Cluster requirement

Clusters must meet the following requirement:

- A cluster cannot be in a peer relationship with more than 255 clusters.

= Use shared or dedicated ports

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use dedicated ports for intercluster communication, or share ports used by the data network. In deciding whether to share ports, you need to consider network

bandwidth, the replication interval, and port availability.

You can share ports on one peered cluster while using dedicated ports on the other.

== Network bandwidth

If you have a high-speed network, such as 10 GbE, you might have enough local LAN bandwidth to perform replication using the same 10 GbE ports used for data access.

Even then, you should compare your available WAN bandwidth to your LAN bandwidth. If the available WAN bandwidth is significantly less than 10 GbE, you might need to use dedicated ports.

The one exception to this rule might be when all or many nodes in the cluster replicate data, in which case bandwidth utilization is typically spread across nodes.

If you are not using dedicated ports, the maximum transmission unit (MTU) size of the replication network should typically be the same as the MTU size of the data network.

== Replication interval

If replication takes place in off-peak hours, you should be able to use data ports for replication even without a 10-GbE LAN connection.

If replication takes place during normal business hours, you need to consider the amount of data that will be replicated and whether it requires so much bandwidth that it could cause contention with data protocols. If network utilization by data protocols (SMB, NFS, iSCSI) is above 50%, you should use dedicated ports for intercluster communication, to allow for non-degraded performance if node failover occurs.

== Port availability

If you determine that replication traffic is interfering with data traffic, you can migrate intercluster LIFs to any other intercluster-capable shared port on the same node.

You can also dedicate VLAN ports for replication. The bandwidth of the port is shared between all VLANs and the base port.

= Use custom IPspaces to isolate replication traffic

:icons: font

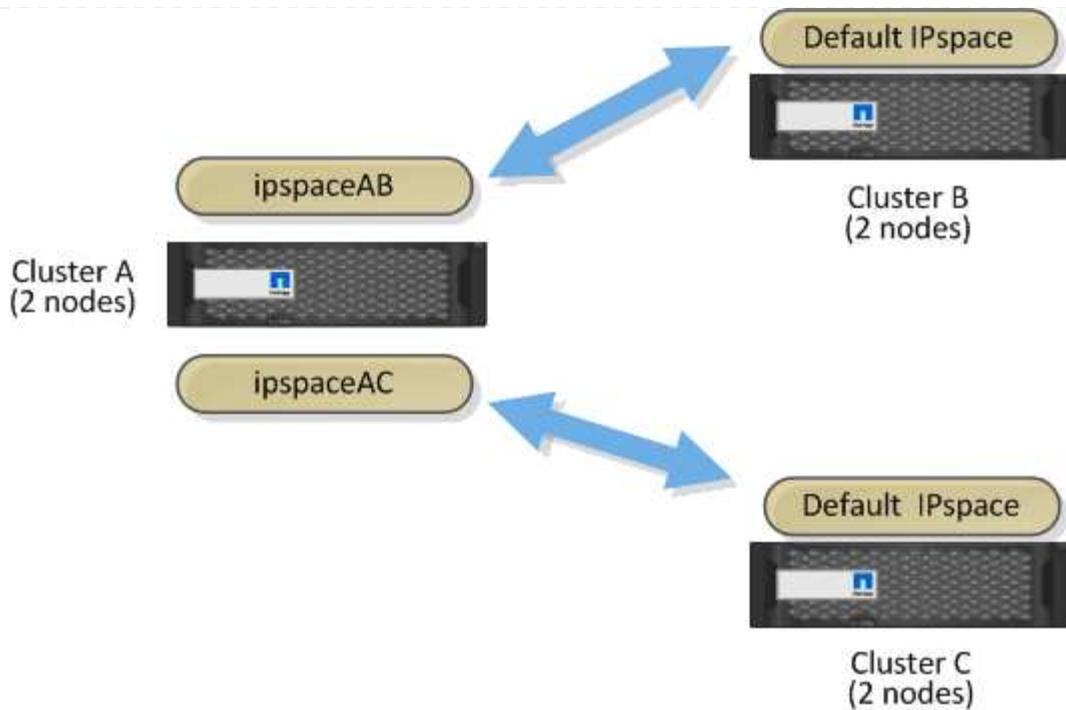

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use custom IPspaces to separate the interactions that a cluster has with its peers. Called *designated intercluster connectivity*, this configuration allows service providers to isolate replication traffic in multitenant environments.

Suppose, for example, that you want replication traffic between Cluster A and Cluster B to be separated from replication traffic between Cluster A and Cluster C. To accomplish this, you can create two IPspaces on Cluster A.

One IPspace contains the intercluster LIFs that you use to communicate with Cluster B. The other contains the intercluster LIFs that you use to communicate with Cluster C, as shown in the following illustration.

For custom IPspace configuration, see the *Network Management Guide*.

= Configure intercluster LIFs

= Configure intercluster LIFs on shared data ports

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can configure intercluster LIFs on ports shared with the data network. Doing so reduces the number of ports you need for intercluster networking.

Steps

1. List the ports in the cluster:

```
network port show
```

For complete command syntax, see the man page.

The following example shows the network ports in `cluster01`:

```

cluster01::> network port show
                                         Speed
                                         (Mbps)
Node    Port      IPspace      Broadcast Domain Link      MTU
Admin/Oper
-----
-----
cluster01-01
    e0a        Cluster       Cluster          up     1500
auto/1000
    e0b        Cluster       Cluster          up     1500
auto/1000
    e0c        Default       Default          up     1500
auto/1000
    e0d        Default       Default          up     1500
auto/1000
cluster01-02
    e0a        Cluster       Cluster          up     1500
auto/1000
    e0b        Cluster       Cluster          up     1500
auto/1000
    e0c        Default       Default          up     1500
auto/1000
    e0d        Default       Default          up     1500
auto/1000

```

2. Create intercluster LIFs on the system SVM:

Option	Description
In ONTAP 9.6 and later:	<code>network interface create -vserver <i>system_SVM</i> -lif <i>LIF_name</i> -service -policy default-intercluster -home -node <i>node</i> -home-port <i>port</i> -address <i>port_IP</i> -netmask <i>netmask</i></code>
In ONTAP 9.5 and earlier:	<code>network interface create -vserver <i>system_SVM</i> -lif <i>LIF_name</i> -role intercluster -home-node <i>node</i> -home -port <i>port</i> -address <i>port_IP</i> -netmask <i>netmask</i></code>

For complete command syntax, see the man page.

The following example creates intercluster LIFs `cluster01_icl01` and `cluster01_icl02`:

```

cluster01::> network interface create -vserver cluster01 -lif
cluster01_icl01 -service-
policy default-intercluster -home-node cluster01-01 -home-port e0c
-address 192.168.1.201
-netmask 255.255.255.0

cluster01::> network interface create -vserver cluster01 -lif
cluster01_icl02 -service-
policy default-intercluster -home-node cluster01-02 -home-port e0c
-address 192.168.1.202
-netmask 255.255.255.0

```

3. Verify that the intercluster LIFs were created:

Option	Description
In ONTAP 9.6 and later:	network interface show -service -policy default-intercluster
In ONTAP 9.5 and earlier:	network interface show -role intercluster

For complete command syntax, see the man page.

```

cluster01::> network interface show -service-policy default-
intercluster
          Logical      Status      Network      Current
Current Is

----- -----
----- -
cluster01
          cluster01_icl01
                  up/up      192.168.1.201/24    cluster01-01
e0c        true
          cluster01_icl02
                  up/up      192.168.1.202/24    cluster01-02
e0c        true

```

4. Verify that the intercluster LIFs are redundant:

Option	Description
In ONTAP 9.6 and later:	network interface show -service-policy default-intercluster -failover
In ONTAP 9.5 and earlier:	network interface show -role intercluster -failover

For complete command syntax, see the man page.

The following example shows that the intercluster LIFs `cluster01_icl01` and `cluster01_icl02` on the `e0c` port will fail over to the `e0d` port.

```
cluster01::> network interface show -service-policy default-
intercluster -failover
      Logical          Home          Failover
      Failover
Vserver  Interface       Node:Port        Policy      Group
-----  -----
-----  -----
cluster01
      cluster01_icl01  cluster01-01:e0c    local-only
      192.168.1.201/24
                           Failover Targets: cluster01-01:e0c,
                                         cluster01-01:e0d
      cluster01_icl02  cluster01-02:e0c    local-only
      192.168.1.201/24
                           Failover Targets: cluster01-02:e0c,
                                         cluster01-02:e0d
```

= Configure intercluster LIFs on dedicated ports

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can configure intercluster LIFs on dedicated ports. Doing so typically increases the available bandwidth for replication traffic.

Steps

1. List the ports in the cluster:

```
network port show
```

For complete command syntax, see the man page.

The following example shows the network ports in `cluster01`:

cluster01::> network port show						Speed (Mbps)
Node	Port	IPspace	Broadcast	Domain	Link	MTU
Admin/Oper						
<hr/>						
<hr/>						
cluster01-01						
	e0a	Cluster	Cluster		up	1500
auto/1000						
	e0b	Cluster	Cluster		up	1500
auto/1000						
	e0c	Default	Default		up	1500
auto/1000						
	e0d	Default	Default		up	1500
auto/1000						
	e0e	Default	Default		up	1500
auto/1000						
	e0f	Default	Default		up	1500
auto/1000						
cluster01-02						
	e0a	Cluster	Cluster		up	1500
auto/1000						
	e0b	Cluster	Cluster		up	1500
auto/1000						
	e0c	Default	Default		up	1500
auto/1000						
	e0d	Default	Default		up	1500
auto/1000						
	e0e	Default	Default		up	1500
auto/1000						
	e0f	Default	Default		up	1500
auto/1000						

2. Determine which ports are available to dedicate to intercluster communication:

network interface show -fields home-port,curr-port

For complete command syntax, see the man page.

The following example shows that ports e0e and e0f have not been assigned LIFs:

```

cluster01::> network interface show -fields home-port,curr-port
vserver lif           home-port curr-port
-----
Cluster cluster01-01_clus1    e0a      e0a
Cluster cluster01-01_clus2    e0b      e0b
Cluster cluster01-02_clus1    e0a      e0a
Cluster cluster01-02_clus2    e0b      e0b
cluster01
    cluster_mgmt        e0c      e0c
cluster01
    cluster01-01_mgmt1   e0c      e0c
cluster01
    cluster01-02_mgmt1   e0c      e0c

```

3. Create a failover group for the dedicated ports:

```

network interface failover-groups create -vserver system_SVM -failover
-group failover_group -targets physical _or_logical_ports

```

The following example assigns ports **e0e** and **e0f** to the failover group **intercluster01** on the system SVM **cluster01**:

```

cluster01::> network interface failover-groups create -vserver
cluster01 -failover-group
intercluster01 -targets
cluster01-01:e0e,cluster01-01:e0f,cluster01-02:e0e,cluster01-02:e0f

```

4. Verify that the failover group was created:

```
network interface failover-groups show
```

For complete command syntax, see the man page.

```

cluster01::> network interface failover-groups show
                           Failover
Vserver          Group      Targets
-----
----- Cluster
Cluster
cluster01-01:e0a, cluster01-
01:e0b,
cluster01-02:e0a, cluster01-02:e0b
cluster01
Default
cluster01-01:e0c, cluster01-
01:e0d,
cluster01-02:e0c, cluster01-
02:e0d,
cluster01-01:e0e, cluster01-01:e0f
cluster01-02:e0e, cluster01-02:e0f
intercluster01
cluster01-01:e0e, cluster01-01:e0f
cluster01-02:e0e, cluster01-02:e0f

```

5. Create intercluster LIFs on the system SVM and assign them to the failover group.

Option	Description
In ONTAP 9.6 and later:	<code>network interface create -vserver <i>system_SVM</i> -lif <i>LIF_name</i> -service -policy default-intercluster -home -node <i>node</i> -home- port <i>port</i> -address <i>port_IP</i> -netmask <i>netmask</i> -failover -group <i>failover_group</i></code>
In ONTAP 9.5 and earlier:	<code>network interface create -vserver <i>system_SVM</i> -lif <i>LIF_name</i> -role intercluster -home-node <i>node</i> -home -port <i>port</i> -address <i>port_IP</i> -netmask <i>netmask</i> -failover-group <i>failover_group</i></code>

For complete command syntax, see the man page.

The following example creates intercluster LIFs `cluster01_icl01` and `cluster01_icl02` in the failover group `intercluster01`:

```

cluster01::> network interface create -vserver cluster01 -lif
cluster01_icl01 -service-
policy default-intercluster -home-node cluster01-01 -home-port e0e
-address 192.168.1.201
-netmask 255.255.255.0 -failover-group intercluster01

cluster01::> network interface create -vserver cluster01 -lif
cluster01_icl02 -service-
policy default-intercluster -home-node cluster01-02 -home-port e0e
-address 192.168.1.202
-netmask 255.255.255.0 -failover-group intercluster01

```

6. Verify that the intercluster LIFs were created:

Option	Description
In ONTAP 9.6 and later:	network interface show -service -policy default-intercluster
In ONTAP 9.5 and earlier:	network interface show -role intercluster

For complete command syntax, see the man page.

```

cluster01::> network interface show -service-policy default-
intercluster
          Logical      Status      Network      Current
Current Is
Vserver     Interface   Admin/Oper Address/Mask      Node
Port       Home
----- -----
----- -
cluster01
          cluster01_icl01
                  up/up      192.168.1.201/24    cluster01-01
e0e        true
          cluster01_icl02
                  up/up      192.168.1.202/24    cluster01-02
e0f        true

```

7. Verify that the intercluster LIFs are redundant:

Option	Description
In ONTAP 9.6 and later:	network interface show -service-policy default-intercluster -failover
In ONTAP 9.5 and earlier:	network interface show -role intercluster -failover

For complete command syntax, see the man page.

The following example shows that the intercluster LIFs `cluster01_icl01` and `cluster01_icl02` on the SVM₀e port will fail over to the e0f port.

```
cluster01::> network interface show -service-policy default-
intercluster -failover
      Logical          Home          Failover
      Failover
Vserver   Interface       Node:Port        Policy      Group
-----  -----
-----  -----
cluster01
      cluster01_icl01  cluster01-01:e0e    local-only
intercluster01
      Failover Targets:  cluster01-01:e0e,
                           cluster01-01:e0f
      cluster01_icl02  cluster01-02:e0e    local-only
intercluster01
      Failover Targets:  cluster01-02:e0e,
                           cluster01-02:e0f
```

= Configure intercluster LIFs in custom IPspaces
:icons: font
:relative_path: ./peering/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can configure intercluster LIFs in custom IPspaces. Doing so allows you to isolate replication traffic in multitenant environments.

When you create a custom IPspace, the system creates a system storage virtual machine (SVM) to serve as a container for the system objects in that IPspace. You can use the new SVM as the container for any intercluster LIFs in the new IPspace. The new SVM has the same name as the custom IPspace.

Steps

1. List the ports in the cluster:

```
network port show
```

For complete command syntax, see the man page.

The following example shows the network ports in cluster01:

Node	Port	IPspace	Broadcast	Domain	Link	MTU	Speed (Mbps)
Admin/Oper							

cluster01-01							
	e0a	Cluster	Cluster		up	1500	
auto/1000							
	e0b	Cluster	Cluster		up	1500	
auto/1000							
	e0c	Default	Default		up	1500	
auto/1000							
	e0d	Default	Default		up	1500	
auto/1000							
	e0e	Default	Default		up	1500	
auto/1000							
	e0f	Default	Default		up	1500	
auto/1000							
cluster01-02							
	e0a	Cluster	Cluster		up	1500	
auto/1000							
	e0b	Cluster	Cluster		up	1500	
auto/1000							
	e0c	Default	Default		up	1500	
auto/1000							
	e0d	Default	Default		up	1500	
auto/1000							
	e0e	Default	Default		up	1500	
auto/1000							
	e0f	Default	Default		up	1500	
auto/1000							

2. Create custom IPspaces on the cluster:

```
network ipspace create -ipspace ipspace
```

The following example creates the custom IPspace ipspace-IC1:

```
cluster01::> network ipspace create -ipspace ipspace-IC1
```

3. Determine which ports are available to dedicate to intercluster communication:

```
network interface show -fields home-port,curr-port
```

For complete command syntax, see the man page.

The following example shows that ports e0e and e0f have not been assigned LIFs:

```
cluster01::> network interface show -fields home-port,curr-port
vserver lif          home-port curr-port
-----
Cluster cluster01_clus1    e0a      e0a
Cluster cluster01_clus2    e0b      e0b
Cluster cluster02_clus1    e0a      e0a
Cluster cluster02_clus2    e0b      e0b
cluster01
    cluster_mgmt        e0c      e0c
cluster01
    cluster01-01_mgmt1   e0c      e0c
cluster01
    cluster01-02_mgmt1   e0c      e0c
```

4. Remove the available ports from the default broadcast domain:

```
network port broadcast-domain remove-ports -broadcast-domain Default -ports
ports
```

A port cannot be in more than one broadcast domain at a time. For complete command syntax, see the man page.

The following example removes ports e0e and e0f from the default broadcast domain:

```
cluster01::> network port broadcast-domain remove-ports -broadcast
-domain Default -ports
cluster01-01:e0e,cluster01-01:e0f,cluster01-02:e0e,cluster01-02:e0f
```

5. Verify that the ports have been removed from the default broadcast domain:

```
network port show
```

For complete command syntax, see the man page.

The following example shows that ports e0e and e0f have been removed from the default broadcast domain:

Node	Port	IPspace	Broadcast Domain	Link	MTU	Speed (Mbps)	Admin/Oper
<hr/>							
cluster01-01	e0a	Cluster	Cluster	up	9000	auto/1000	
	e0b	Cluster	Cluster	up	9000	auto/1000	
	e0c	Default	Default	up	1500	auto/1000	
	e0d	Default	Default	up	1500	auto/1000	
	e0e	Default	-	up	1500	auto/1000	
	e0f	Default	-	up	1500	auto/1000	
	e0g	Default	Default	up	1500	auto/1000	
cluster01-02	e0a	Cluster	Cluster	up	9000	auto/1000	
	e0b	Cluster	Cluster	up	9000	auto/1000	
	e0c	Default	Default	up	1500	auto/1000	
	e0d	Default	Default	up	1500	auto/1000	
	e0e	Default	-	up	1500	auto/1000	
	e0f	Default	-	up	1500	auto/1000	
	e0g	Default	Default	up	1500	auto/1000	

6. Create a broadcast domain in the custom IPspace:

```
network port broadcast-domain create -ipspace ipspace -broadcast-domain
broadcast_domain -mtu MTU -ports ports
```

The following example creates the broadcast domain `ipspace-IC1-bd` in the IPspace `ipspace-IC1`:

```
cluster01::> network port broadcast-domain create -ipspace ipspace-
IC1 -broadcast-domain
ipspace-IC1-bd -mtu 1500 -ports cluster01-01:e0e,cluster01-01:e0f,
cluster01-02:e0e,cluster01-02:e0f
```

7. Verify that the broadcast domain was created:

```
network port broadcast-domain show
```

For complete command syntax, see the man page.

```

cluster01::> network port broadcast-domain show
IPspace Broadcast                                         Update
Name    Domain Name     MTU   Port List                  Status
Details
-----
----- Cluster Cluster      9000

                                         cluster01-02:e0f      complete

```

8. Create intercluster LIFs on the system SVM and assign them to the broadcast domain:

Option	Description
In ONTAP 9.6 and later:	<pre>network interface create -vserver system_SVM -lif <i>LIF_name</i> -service -policy default-intercluster -home -node <i>node</i> -home-port <i>port</i> -address <i>port_IP</i> -netmask <i>netmask</i></pre>
In ONTAP 9.5 and earlier:	<pre>network interface create -vserver system_SVM -lif <i>LIF_name</i> -role intercluster -home-node <i>node</i> -home -port <i>port</i> -address <i>port_IP</i> -netmask <i>netmask</i></pre>

The LIF is created in the broadcast domain that the home port is assigned to. The broadcast domain has a default failover group with the same name as the broadcast domain. For complete command

syntax, see the man page.

The following example creates intercluster LIFs `cluster01_icl01` and `cluster01_icl02` in the broadcast domain `ipspace-IC1-bd`:

```
cluster01::> network interface create -vserver ipspace-IC1 -lif
cluster01_icl01 -service-
policy default-intercluster -home-node cluster01-01 -home-port e0e
-address 192.168.1.201
-netmask 255.255.255.0

cluster01::> network interface create -vserver ipspace-IC1 -lif
cluster01_icl02 -service-
policy default-intercluster -home-node cluster01-02 -home-port e0e
-address 192.168.1.202
-netmask 255.255.255.0
```

9. Verify that the intercluster LIFs were created:

Option	Description
In ONTAP 9.6 and later:	<code>network interface show -service-policy default-intercluster</code>
In ONTAP 9.5 and earlier:	<code>network interface show -role intercluster</code>

For complete command syntax, see the man page.

```
cluster01::> network interface show -service-policy default-
intercluster
          Logical      Status      Network        Current
Current Is
Vserver     Interface   Admin/Oper Address/Mask       Node
Port       Home
-----
-----
ipspace-IC1
          cluster01_icl01
                      up/up      192.168.1.201/24    cluster01-01
e0e        true
          cluster01_icl02
                      up/up      192.168.1.202/24    cluster01-02
e0f        true
```

10. Verify that the intercluster LIFs are redundant:

Option	Description
In ONTAP 9.6 and later:	<code>network interface show -service-policy default-intercluster -failover</code>
In ONTAP 9.5 and earlier:	<code>network interface show -role intercluster -failover</code>

For complete command syntax, see the man page.

The following example shows that the intercluster LIFs `cluster01_icl01` and `cluster01_icl02` on the SVM `e0e` port fail over to the `e0f` port:

```
cluster01::> network interface show -service-policy default-
intercluster -failover
      Logical          Home          Failover
      Failover
Vserver  Interface       Node:Port        Policy      Group
-----  -----
-----  -----
  ipspace-IC1
      cluster01_icl01  cluster01-01:e0e   local-only
intercluster01
                      Failover Targets:  cluster01-01:e0e,
                                         cluster01-01:e0f
      cluster01_icl02  cluster01-02:e0e   local-only
intercluster01
                      Failover Targets:  cluster01-02:e0e,
                                         cluster01-02:e0f
```

= Configure peer relationships (ONTAP 9.3 and later)

= Create a cluster peer relationship (ONTAP 9.3 and later)

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use the `cluster peer create` command to create a peer relationship between a local and remote cluster. After the peer relationship has been created, you can run `cluster peer create` on the remote cluster to authenticate it to the local cluster.

What you'll need

- You must have created intercluster LIFs on every node in the clusters that are being peered.
- The clusters must be running ONTAP 9.3 or later.

Steps

1. On the destination cluster, create a peer relationship with the source cluster:

```
cluster peer create -generate-passphrase -offer-expiration MM/DD/YYYY
HH:MM:SS|1...7days|1...168hours -peer-addrs peer_LIF_IPs -initial-allowed
-vserver-peers svm_name,...|^* -ipspace ipspace
```

If you specify both `-generate-passphrase` and `-peer-addrs`, only the cluster whose intercluster LIFs are specified in `-peer-addrs` can use the generated password.

You can ignore the `-ipspace` option if you are not using a custom IPspace. For complete command syntax, see the man page.

If you are creating the peering relationship in ONTAP 9.6 or later and you do not want cross-cluster peering communications to be encrypted, you must use the `-encryption-protocol-proposed none` option to disable encryption.

The following example creates a cluster peer relationship with an unspecified remote cluster, and pre-authorizes peer relationships with SVMs `vs1` and `vs2` on the local cluster:

```
cluster02::> cluster peer create -generate-passphrase -offer
-expiration 2days -initial-allowed-vserver-peers vs1,vs2

Passphrase: UCa+6lRVICXeL/gq1WrK7ShR
Expiration Time: 6/7/2017 08:16:10 EST
Initial Allowed Vserver Peers: vs1,vs2
Intercluster LIF IP: 192.140.112.101
Peer Cluster Name: Clus_7ShR (temporary generated)
```

Warning: make a note of the passphrase - it cannot be displayed again.

The following example creates a cluster peer relationship with the remote cluster at intercluster LIF IP addresses `192.140.112.103` and `192.140.112.104`, and pre-authorizes a peer relationship with any SVM on the local cluster:

```
cluster02::> cluster peer create -generate-passphrase -peer-addrs  
192.140.112.103,192.140.112.104 -offer-expiration 2days -initial  
-allowed-vserver-peers *
```

```
Passphrase: UCa+6lRVICXeL/gq1WrK7ShR  
Expiration Time: 6/7/2017 08:16:10 EST  
Initial Allowed Vserver Peers: vs1,vs2  
Intercluster LIF IP: 192.140.112.101,192.140.112.102  
Peer Cluster Name: Clus_7ShR (temporary generated)
```

Warning: make a note of the passphrase - it cannot be displayed again.

The following example creates a cluster peer relationship with an unspecified remote cluster, and pre-authorizes peer relationships with SVMs vs1 and vs2 on the local cluster:

```
cluster02::> cluster peer create -generate-passphrase -offer  
-expiration 2days -initial-allowed-vserver-peers vs1,vs2  
  
Passphrase: UCa+6lRVICXeL/gq1WrK7ShR  
Expiration Time: 6/7/2017 08:16:10 EST  
Initial Allowed Vserver Peers: vs1,vs2  
Intercluster LIF IP: 192.140.112.101  
Peer Cluster Name: Clus_7ShR (temporary generated)
```

Warning: make a note of the passphrase - it cannot be displayed again.

2. On source cluster, authenticate the source cluster to the destination cluster:

```
cluster peer create -peer-addrs peer_LIF_IPs -ipspace ipspace
```

For complete command syntax, see the man page.

The following example authenticates the local cluster to the remote cluster at intercluster LIF IP addresses 192.140.112.101 and 192.140.112.102:

```
cluster01::> cluster peer create -peer-addrs  
192.140.112.101,192.140.112.102
```

Notice: Use a generated passphrase or choose a passphrase of 8 or more characters.

To ensure the authenticity of the peering relationship, use a phrase or sequence of characters that would be hard to guess.

Enter the passphrase:

Confirm the passphrase:

Clusters cluster02 and cluster01 are peered.

Enter the passphrase for the peer relationship when prompted.

3. Verify that the cluster peer relationship was created:

```
cluster peer show -instance
```

```
cluster01::> cluster peer show -instance

                  Peer Cluster Name: cluster02
                  Remote Intercluster Addresses: 192.140.112.101,
192.140.112.102
                  Availability of the Remote Cluster: Available
                  Remote Cluster Name: cluster2
                  Active IP Addresses: 192.140.112.101,
192.140.112.102
                  Cluster Serial Number: 1-80-123456
                  Address Family of Relationship: ipv4
                  Authentication Status Administrative: no-authentication
                  Authentication Status Operational: absent
                  Last Update Time: 02/05 21:05:41
                  IPspace for the Relationship: Default
```

4. Check the connectivity and status of the nodes in the peer relationship:

```
cluster peer health show
```

```

cluster01::> cluster peer health show
Node          cluster-Name           Node-Name
              Ping-Status          RDB-Health Cluster-Health
Avail...
-----
-----
cluster01-01
          cluster02          cluster02-01
          Data: interface_reachable
          ICMP: interface_reachable true      true
true
          cluster02-02

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
The redesigned System Manager (available with ONTAP 9.7 and later)	Prepare for mirroring and vaulting
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume disaster recovery preparation overview

= Create an intercluster SVM peer relationship (ONTAP 9.3 and later)

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use the `vserver peer create` command to create a peer relationship between SVMs on local and remote clusters.

What you'll need

- The source and destination clusters must be peered.
- The clusters must be running ONTAP 9.3.

- You must have "pre-authorized" peer relationships for the SVMs on the remote cluster.

For more information, see [Creating a cluster peer relationship \(ONTAP 9.3 and later\)](#).

About this task

Previous releases of ONTAP let you authorize a peer relationship for only one SVM at a time. You needed to run the `vserver peer accept` command each time you authorized a pending SVM peer relationship.

Beginning with ONTAP 9.3, you can "pre-authorize" peer relationships for multiple SVMs by listing the SVMs in the `-initial-allowed-vserver` option when you create a cluster peer relationship. For more information, see [Creating a cluster peer relationship \(ONTAP 9.3 and later\)](#).

Steps

1. On the data protection destination cluster, display the SVMs that are pre-authorized for peering:

```
vserver peer permission show
```

cluster02::> vserver peer permission show		
Peer Cluster	Vserver	Applications
cluster02	vs1,vs2	snapmirror

2. On the data protection source cluster, create a peer relationship to a pre-authorized SVM on the data protection destination cluster:

```
vserver peer create -vserver local_SVM -peer-vserver remote_SVM
```

For complete command syntax, see the man page.

The following example creates a peer relationship between the local SVM `pvs1` and the pre-authorized remote SVM `vs1`:

```
cluster01::> vserver peer create -vserver pvs1 -peer-vserver vs1
```

3. Verify the SVM peer relationship:

```
vserver peer show
```

```

cluster01::> vserver peer show
      Peer          Peer          Peering
  Remote
  Vserver    Vserver    State    Peer Cluster   Applications
  Vserver
  -----
  -----
  pvs1        vs1        peered   cluster02   snapmirror
  vs1

```

= Add an intercluster SVM peer relationship (ONTAP 9.3 and later)

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

If you create an SVM after configuring a cluster peer relationship, you will need to add a peer relationship for the SVM manually. You can use the `vserver peer create` command to create a peer relationship between SVMs. After the peer relationship has been created, you can run `vserver peer accept` on the remote cluster to authorize the peer relationship.

What you'll need

The source and destination clusters must be peered.

About this task

You can create a peer relationships between SVMs in the same cluster for local data backup. For more information, see the `vserver peer create` man page.

Administrators occasionally use the `vserver peer reject` command to reject a proposed SVM peer relationship. If the relationship between SVMs is in the rejected state, you must delete the relationship before you can create a new one. For more information, see the `vserver peer delete` man page.

Steps

1. On the data protection source cluster, create a peer relationship with an SVM on the data protection destination cluster:

```
vserver peer create -vserver local_SVM -peer-vserver remote_SVM
-applications snapmirror|file-copy|lun-copy -peer-cluster remote_cluster
```

The following example creates a peer relationship between the local SVM `pvs1` and the remote SVM `vs1`

```
cluster01::> vserver peer create -vserver pvs1 -peer-vserver vs1
-applications snapmirror -peer-cluster cluster02
```

If the local and remote SVMs have the same names, you must use a *local name* to create the SVM

peer relationship:

```
cluster01::> vserver peer create -vserver vs1 -peer-vserver  
vs1 -applications snapmirror -peer-cluster cluster01  
-local-name cluster1vs1LocallyUniqueName
```

2. On the data protection source cluster, verify that the peer relationship has been initiated:

```
vserver peer show-all
```

For complete command syntax, see the man page.

The following example shows that the peer relationship between SVM_{pvs1} and SVM_{vs1} has been initiated:

```
cluster01::> vserver peer show-all  
          Peer          Peer  
Peering  
Vserver      Vserver      State      Peer Cluster  
Applications  
-----  
-----  
pvs1          vs1        initiated   Cluster02  
snapmirror
```

3. On the data protection destination cluster, display the pending SVM peer relationship:

```
vserver peer show
```

For complete command syntax, see the man page.

The following example lists the pending peer relationships for cluster02:

```
cluster02::> vserver peer show  
          Peer          Peer  
Vserver      Vserver      State  
-----  
-----  
vs1          pvs1        pending
```

4. On the data protection destination cluster, authorize the pending peer relationship:

```
vserver peer accept -vserver local_SVM -peer-vserver remote_SVM
```

For complete command syntax, see the man page.

The following example authorizes the peer relationship between the local SVM `vs1` and the remote SVM `pvs1`:

```
cluster02::> vserver peer accept -vserver vs1 -peer-vserver pvs1
```

5. Verify the SVM peer relationship:

```
vserver peer show
```

```
cluster01::> vserver peer show
      Peer          Peer          Peering
  Remote
Vserver    Vserver    State    Peer Cluster   Applications
Vserver
-----
-----
pvs1        vs1       peered   cluster02     snapmirror
vs1
```

= Configure peer relationships (ONTAP 9.2 and earlier)

= Create a cluster peer relationship (ONTAP 9.2 and earlier)

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./encryption-at-rest./media/

You can use the `cluster peer create` command to initiate a request for a peering relationship between a local and remote cluster. After the peer relationship has been requested by the local cluster, you can run `cluster peer create` on the remote cluster to accept the relationship.

What you'll need

- You must have created intercluster LIFs on every node in the clusters being peered.
- The cluster administrators must have agreed on the passphrase each cluster will use to authenticate itself to the other.

Steps

1. On the data protection destination cluster, create a peer relationship with the data protection source cluster:

```
cluster peer create -peer-addrs peer_LIF_IPs -ipspace ipspace
```

You can ignore the `-ipspace` option if you are not using a custom IPspace. For complete command syntax, see the man page.

The following example creates a cluster peer relationship with the remote cluster at intercluster LIF IP addresses 192.168.2.201 and 192.168.2.202:

```
cluster02::> cluster peer create -peer-addrs  
192.168.2.201,192.168.2.202  
Enter the passphrase:  
Please enter the passphrase again:
```

Enter the passphrase for the peer relationship when prompted.

2. On the data protection source cluster, authenticate the source cluster to the destination cluster:

```
cluster peer create -peer-addrs peer_LIF_IPs -ipspace ipspace
```

For complete command syntax, see the man page.

The following example authenticates the local cluster to the remote cluster at intercluster LIF IP addresses 192.140.112.203 and 192.140.112.204:

```
cluster01::> cluster peer create -peer-addrs  
192.168.2.203,192.168.2.204  
Please confirm the passphrase:  
Please confirm the passphrase again:
```

Enter the passphrase for the peer relationship when prompted.

3. Verify that the cluster peer relationship was created:

```
cluster peer show -instance
```

For complete command syntax, see the man page.

```
cluster01::> cluster peer show -instance  
Peer Cluster Name: cluster01  
Remote Intercluster Addresses: 192.168.2.201,192.168.2.202  
Availability: Available  
Remote Cluster Name: cluster02  
Active IP Addresses: 192.168.2.201,192.168.2.202  
Cluster Serial Number: 1-80-000013
```

4. Check the connectivity and status of the nodes in the peer relationship:

```
cluster peer health show
```

For complete command syntax, see the man page.

```

cluster01::> cluster peer health show
Node          cluster-Name           Node-Name
              Ping-Status          RDB-Health Cluster-Health
Avail...
-----
-----
cluster01-01

          cluster02-02
          Data: interface_reachable
          ICMP: interface_reachable true      true
true

```

= Create an intercluster SVM peer relationship (ONTAP 9.2 and earlier)

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use the `vserver peer create` command to create a peer relationship between SVMs on local and remote clusters. After the peer relationship has been created, you can run `vserver peer accept` on the remote cluster to authorize the peer relationship.

What you'll need

The source and destination clusters must be peered.

About this task

You can create a peer relationships between SVMs in the same cluster for local data backup. For more information, see the `vserver peer create` man page.

Administrators occasionally use the `vserver peer reject` command to reject a proposed SVM peer relationship. If the relationship between SVMs is in the rejected state, you must delete the relationship before you can create a new one. For more information, see the `vserver peer delete` man page.

Steps

1. On the data protection source cluster, create a peer relationship with an SVM on the data protection destination cluster:

```
vserver peer create -vserver local_SVM -peer-vserver remote_SVM  
-applications snapmirror|file-copy|lun-copy -peer-cluster remote_cluster
```

The following example creates a peer relationship between the local SVM `pvs1` and the remote SVM `vs1`:

```
cluster01::> vserver peer create -vserver pvs1 -peer-vserver vs1  
-applications snapmirror -peer-cluster cluster02
```

If the local and remote SVMs have the same names, you must use a *local name* to create the SVM peer relationship:

```
cluster01::> vserver peer create -vserver vs1 -peer-vserver  
vs1 -applications snapmirror -peer-cluster cluster01  
-local-name cluster1vs1LocallyUniqueName
```

2. On the data protection source cluster, verify that the peer relationship has been initiated:

```
vserver peer show-all
```

For complete command syntax, see the man page.

The following example shows that the peer relationship between SVM `pvs1` and SVM `vs1` has been initiated:

```
cluster01::> vserver peer show-all  
          Peer           Peer  
Peering  
Vserver      Vserver      State     Peer Cluster  
Applications  
-----  
-----  
pvs1        vs1        initiated   Cluster02  
snapmirror
```

3. On the data protection destination cluster, display the pending SVM peer relationship:

```
vserver peer show
```

For complete command syntax, see the man page.

The following example lists the pending peer relationships for `cluster02`:

```
cluster02::> vserver peer show
```

Vserver	Peer Vserver	Peer State
vs1	pvs1	pending

4. On the data protection destination cluster, authorize the pending peer relationship:

```
vserver peer accept -vserver local_SVM -peer-vserver remote_SVM
```

For complete command syntax, see the man page.

The following example authorizes the peer relationship between the local SVM vs1 and the remote SVM pvs1:

```
cluster02::> vserver peer accept -vserver vs1 -peer-vserver pvs1
```

5. Verify the SVM peer relationship:

```
vserver peer show
```

cluster01::> vserver peer show				
Remote	Vserver	Peer Vserver	State	Peering
Vserver				Peer Cluster Applications
Vserver				
-----	-----	-----	-----	-----
pvs1	vs1		peered	cluster02 snapmirror
vs1				

= Enable cluster peering encryption on an existing peer relationship

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

Beginning with ONTAP 9.6, cluster peering encryption is enabled by default on all newly created cluster peering relationships. Cluster peering encryption uses a pre-shared key (PSK) and the Transport Security Layer (TLS) to secure cross-cluster peering communications. This adds an additional layer of security between the peered clusters.

About this task

If you are upgrading peered clusters to ONTAP 9.6 or later, and the peering relationship was created in

ONTAP 9.5 or earlier, cluster peering encryption must be enabled manually after upgrading. Both clusters in the peering relationship must be running ONTAP 9.6 or later in order to enable cluster peering encryption.

Steps

1. On the destination cluster, enable encryption for communications with the source cluster:

```
cluster peer modify source_cluster -auth-status-admin use-authentication  
-encryption-protocol-proposed tls-psk
```

2. When prompted enter a passphrase.

3. On the data protection source cluster, enable encryption for communication with the data protection destination cluster:

```
cluster peer modify data_protection_destination_cluster -auth-status-admin  
use-authentication -encryption-protocol-proposed tls-psk
```

4. When prompted, enter the same passphrase entered on the destination cluster.

= Remove cluster peering encryption from an existing peer relationship

:icons: font

:relative_path: ./peering/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

By default, cluster peering encryption is enabled on all peer relationships created in ONTAP 9.6 or later. If you do not want to use encryption for cross-cluster peering communications, you can disable it.

Steps

1. On the destination cluster, modify communications with the source cluster to discontinue use of cluster peering encryption :

- To remove encryption, but maintain authentication enter:

```
cluster peer modify source_cluster -auth-status-admin use-authentication  
-encryption none
```

- To remove encryption and authentication, enter:

```
cluster peer modify source_cluster -auth-status no-authentication
```

2. When prompted enter a passphrase.

3. On the source cluster, disable encryption for communication with the destination cluster:

- To remove encryption, but maintain authentication enter:

```
cluster peer modify destination_cluster -auth-status-admin use-  
authentication -encrypt none
```

- To remove encryption and authentication, enter:

```
cluster peer modify destination_cluster -auth-status no-authentication
```

4. When prompted, enter the same passphrase entered on the destination cluster.

= Where to find additional information

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

You can use CLI commands to manage Snapshot copies on a local ONTAP system and to replicate Snapshot copies to a remote system using SnapMirror. You can replicate Snapshot copies for disaster recovery or long-term retention.

Use these procedures under the following circumstances:

- You want to understand the range of ONTAP backup and recovery capabilities.

- You want to use the command-line interface (CLI), not System Manager, an automated scripting tool, or a SnapCenter product.
- You have already created peer relationships between the source and destination clusters and the source and destination SVMs.

[Cluster and SVM peering](#)

- You are backing up volumes or SVMs from AFF or FAS storage systems to AFF or FAS storage systems.
 - If you are replicating Element volumes to ONTAP, or ONTAP LUNs to an Element system, see the NetApp Element software documentation.

[Replication between NetApp element software and ONTAP](#)

- Beginning with ONTAP 9.10.1, you can create data protection relationships between S3 buckets using S3 SnapMirror. For more information, see [S3 SnapMirror overview](#).
- You want to provide data protection using online methods, not tape.

== Other ways to do this in ONTAP

To perform these tasks with...	Refer to...
The redesigned System Manager (available with ONTAP 9.7 and later)	Prepare for mirroring and vaulting
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume disaster recovery preparation overview

= Manage local Snapshot copies

= Manage local Snapshot copies overview

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

A **Snapshot copy** is a read-only, point-in-time image of a volume. The image consumes minimal storage space and incurs negligible performance overhead because it records only changes to files since the last Snapshot copy.

You can use a Snapshot copy to restore the entire contents of a volume, or to recover individual files or LUNs. Snapshot copies are stored in the directory `.snapshot` on the volume.

In ONTAP 9.3 and earlier, a volume can contain up to 255 Snapshot copies. In ONTAP 9.4 and later, a FlexVol volume can contain up to 1023 Snapshot copies.

Beginning with ONTAP 9.8, FlexGroup volumes can contain 1023 Snapshot copies. For more information, see [Protect FlexGroup volumes using Snapshot copies](#).

= Configure custom Snapshot policies

= Configure custom Snapshot policies overview

:icons: font

:relative_path: ./data-protection/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/
```

A *Snapshot policy* defines how the system creates Snapshot copies. The policy specifies when to create Snapshot copies, how many copies to retain, and how to name them. For example, a system might create one Snapshot copy every day at 12:10 a.m., retain the two most recent copies, and name the copies “*daily.timestamp*.”

The default policy for a volume automatically creates Snapshot copies on the following schedule, with the oldest Snapshot copies deleted to make room for newer copies:

- A maximum of six hourly Snapshot copies taken five minutes past the hour.
- A maximum of two daily Snapshot copies taken Monday through Saturday at 10 minutes after midnight.
- A maximum of two weekly Snapshot copies taken every Sunday at 15 minutes after midnight.

Unless you specify a Snapshot policy when you create a volume, the volume inherits the Snapshot policy associated with its containing storage virtual machine (SVM).

= When to configure a custom Snapshot policy

:icons: font

:relative_path: ./data-protection/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/
```

If the default Snapshot policy is not appropriate for a volume, you can configure a custom policy that modifies the frequency, retention, and name of Snapshot copies. The schedule will be dictated mainly by the rate of change of the active file system.

You might back up a heavily used file system like a database every hour, while you back up rarely used files once a day. Even for a database, you will typically run a full backup once or twice a day, while backing up transaction logs every hour.

Other factors are the importance of the files to your organization, your Service Level Agreement (SLA), your Recovery Point Objective (RPO), and your Recovery Time Objective (RTO). Generally speaking, you should retain only as many Snapshot copies as necessary.

= Create a Snapshot job schedule

:icons: font

:relative_path: ./data-protection/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/
```

A Snapshot policy requires at least one Snapshot copy job schedule. You can use the `job schedule cron create` command to create a job schedule.

About this task

By default, ONTAP forms the names of Snapshot copies by appending a timestamp to the job schedule name.

If you specify values for both day of the month and day of the week, the values are considered independently. For example, a cron schedule with the day specification `Friday` and the day of the month specification `13` runs every Friday and on the 13th day of each month, not just on every Friday the 13th.

Step

1. Create a job schedule:

```
job schedule cron create -name job_name -month month -dayofweek day_of_week  
-day day_of_month -hour hour -minute minute
```

For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the week, and hour, respectively.

Beginning with ONTAP 9.10.1, you can include the Vserver for your job schedule:

```
job schedule cron create -name job_name -vserver Vserver_name -month month  
-dayofweek day_of_week -day day_of_month -hour hour -minute minute
```

The following example creates a job schedule named `myweekly` that runs on Saturdays at 3:00 a.m.:

```
cluster1::> job schedule cron create -name myweekly -dayofweek  
"Saturday" -hour 3 -minute 0
```

The following example creates a schedule named `myweeklymulti` that specifies multiple days, hours and minutes:

```
job schedule cron create -name myweeklymulti -dayofweek  
"Monday,Wednesday,Sunday" -hour 3,9,12 -minute 0,20,50
```

= Create a Snapshot policy

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

A Snapshot policy specifies when to create Snapshot copies, how many copies to retain, and how to name them. For example, a system might create one Snapshot copy every day at 12:10 a.m., retain the two most recent copies, and name them “`daily.timestamp`.” A Snapshot policy can contain up to five job schedules.

About this task

By default, ONTAP forms the names of Snapshot copies by appending a timestamp to the job schedule name:

daily.2017-05-14_0013/	hourly.2017-05-15_1106/
daily.2017-05-15_0012/	hourly.2017-05-15_1206/
hourly.2017-05-15_1006/	hourly.2017-05-15_1306/

You can substitute a prefix for the job schedule name if you prefer.

The `snapmirror-label` option is for SnapMirror replication. For more information, see [Defining a rule](#)

for a policy.

Step

1. Create a Snapshot policy:

```
volume snapshot policy create -vserver SVM -policy policy_name -enabled true|false -schedule1 schedule1_name -count1 copies_to_retain -prefix1 snapshot_prefix -snapmirror-label1 snapshot_label ... -schedule1 schedule5_name -count5 copies_to_retain-prefix5 snapshot_prefix -snapmirror -label5 snapshot_label
```

The following example creates a Snapshot policy named `snap_policy_daily` that runs on a daily schedule. The policy has a maximum of five Snapshot copies, each with the name `daily.timestamp` and the SnapMirror label `daily`:

```
cluster1::> volume snapshot policy create -vserver vs0 -policy snap_policy_daily -schedule1 daily -count1 5 -snapmirror-label1 daily
```

= Manage the Snapshot copy reserve

= Manage the Snapshot copy reserve overview

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

The *Snapshot copy reserve* sets aside a percentage of disk space for Snapshot copies, five percent by default. Because Snapshot copies use space in the active file system when the Snapshot copy reserve is exhausted, you might want to increase the Snapshot copy reserve as needed. Alternatively, you can autodelete Snapshot copies when the reserve is full.

= When to increase the Snapshot copy reserve

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

In deciding whether to increase the Snapshot reserve, it's important to remember that a Snapshot copy records only changes to files since the last Snapshot copy was made. It consumes disk space only when blocks in the active file system are modified or deleted.

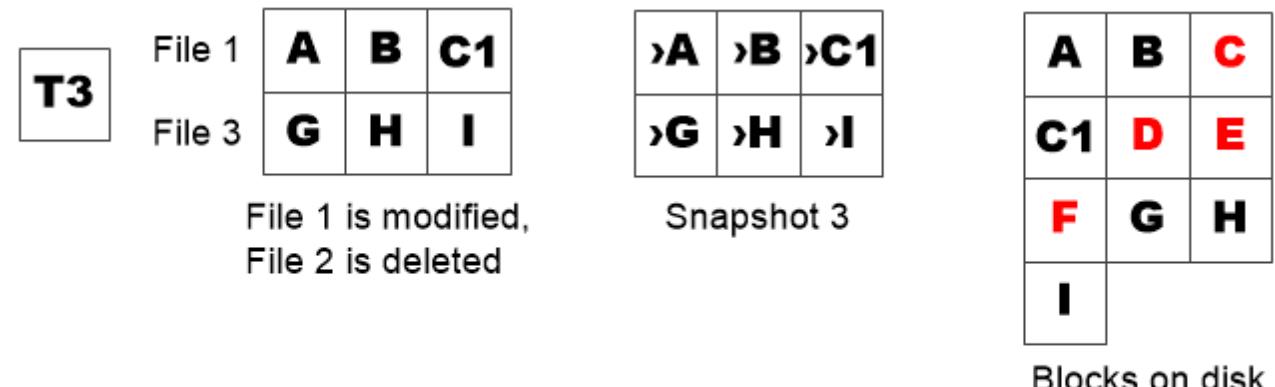

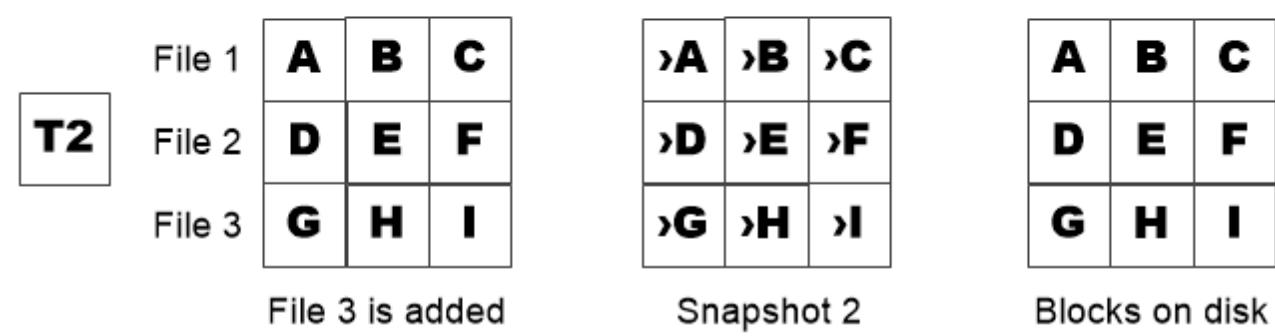

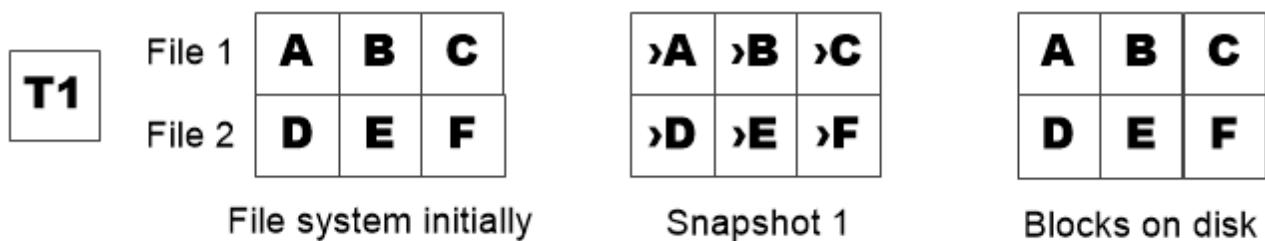

This means that the rate of change of the file system is the key factor in determining the amount of disk space used by Snapshot copies. No matter how many Snapshot copies you create, they will not consume disk space if the active file system has not changed.

A FlexVol volume containing database transaction logs, for example, might have a Snapshot copy reserve as large as 20% to account for its greater rate of change. Not only will you want to create more Snapshot copies to capture the more frequent updates to the database, you will also want to have a larger

Snapshot copy reserve to handle the additional disk space the Snapshot copies consume.

A Snapshot copy consists of pointers to blocks rather than copies of blocks. You can think of a pointer as a “claim” on a block: ONTAP “holds” the block until the Snapshot copy is deleted.

A Snapshot copy consumes disk space only when blocks in the active file system are modified or deleted.

= How deleting protected files can lead to less file space than expected

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

A Snapshot copy points to a block even after you delete the file that used the block. This explains why an exhausted Snapshot copy reserve might lead to the counter-intuitive result in which deleting an entire file system results in less space being available than the file system occupied.

Consider the following example. Before deleting any files, the `df` command output is as follows:

```

Filesystem      kbytes  used   avail capacity
/vol/vol0/      3000000 3000000 0       100%
/vol/vol0/.snapshot 1000000 500000 500000 50%

```

After deleting the entire file system and making a Snapshot copy of the volume, the `df` command generates the following output:

```

Filesystem      kbytes  used   avail capacity
/vol/vol0/      3000000 2500000 500000 83%
/vol/vol0/.snapshot 1000000 3500000 0       350%

```

As the output shows, the entire 3 GB formerly used by the active file system is now being used by Snapshot copies, in addition to the 0.5 GB used before the deletion.

Because the disk space used by the Snapshot copies now exceeds the Snapshot copy reserve, the overflow of 2.5 GB “spills” into the space reserved for active files, leaving you with 0.5 GB free space for files where you might reasonably have expected 3 GB.

= Monitor Snapshot copy disk consumption

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can monitor Snapshot copy disk consumption using the `df` command. The command displays the amount of free space in the active file system and the Snapshot copy reserve.

Step

1. Display Snapshot copy disk consumption: `df`

The following example shows Snapshot copy disk consumption:

```

cluster1::> df
Filesystem      kbytes  used   avail capacity
/vol/vol0/      3000000 3000000 0       100%
/vol/vol0/.snapshot 1000000 500000 500000 50%

```

= Check available Snapshot copy reserve on a volume

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You might want to check how much Snapshot copy reserve is available on a volume by using the `snapshot-reserve-available` parameter with the `volume show` command.

Step

1. Check the Snapshot copy reserve available on a volume:

```
vol show -vserver SVM -volume volume -fields snapshot-reserve-available
```

For complete command syntax, see the man page.

The following example displays the available Snapshot copy reserve for `vol1`:

```
cluster1::> vol show -vserver vs0 -volume vol1 -fields snapshot-
reserve-available

vserver volume snapshot-reserve-available
-----
vs0      vol1    4.84GB
```

= Modify the Snapshot copy reserve

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You might want to configure a larger Snapshot copy reserve to prevent Snapshot copies from using space reserved for the active file system. You can decrease the Snapshot copy reserve when you no longer need as much space for Snapshot copies.

Step

1. Modify the Snapshot copy reserve:

```
volume modify -vserver SVM -volume volume -percent-snapshot-space
snap_reserve
```

For complete command syntax, see the man page.

The following example sets the Snapshot copy reserve for `vol1` to 10 percent:

```
cluster1::> volume modify -vserver vs0 -volume vol1 -percent
-snapshot-space 10
```

= Autodelete Snapshot copies

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use the `volume snapshot autodelete modify` command to trigger automatic deletion of Snapshot copies when the Snapshot reserve is exceeded. By

default, the oldest Snapshot copies are deleted first.

About this task

LUN and file clones are deleted when there are no more Snapshot copies to be deleted.

Step

1. Autodelete Snapshot copies:

```
volume snapshot autodelete modify -vserver SVM -volume volume -enabled  
true|false -trigger volume|snap_reserve
```

For complete command syntax, see the man page.

The following example autodeletes Snapshot copies for `vol1` when the Snapshot copy reserve is exhausted:

```
cluster1::> volume snapshot autodelete modify -vserver vs0 -volume  
vol1 -enabled true -trigger snap_reserve
```

= Restore files from Snapshot copies

= Restore a file from a Snapshot copy on an NFS or SMB client

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

A user on an NFS or SMB client can restore a file directly from a Snapshot copy without the intervention of a storage system administrator.

Every directory in the file system contains a subdirectory named `.snapshot` accessible to NFS and SMB users. The `.snapshot` subdirectory contains subdirectories corresponding to the Snapshot copies of the volume:

```
$ ls .snapshot  
daily.2017-05-14_0013/          hourly.2017-05-15_1106/  
daily.2017-05-15_0012/          hourly.2017-05-15_1206/  
hourly.2017-05-15_1006/         hourly.2017-05-15_1306/
```

Each subdirectory contains the files referenced by the Snapshot copy. If users accidentally delete or overwrite a file, they can restore the file to the parent read-write directory by copying the file from the Snapshot subdirectory to the read-write directory:

```

$ ls my.txt
ls: my.txt: No such file or directory
$ ls .snapshot
daily.2017-05-14_0013/          hourly.2017-05-15_1106/
daily.2017-05-15_0012/          hourly.2017-05-15_1206/
hourly.2017-05-15_1006/         hourly.2017-05-15_1306/
$ ls .snapshot/hourly.2017-05-15_1306/my.txt
my.txt
$ cp .snapshot/hourly.2017-05-15_1306/my.txt .
$ ls my.txt
my.txt

```

= Enable and disable NFS and SMB client access to Snapshot copy directory

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

To determine whether the Snapshot copy directory is visible to NFS and SMB clients to restore a file or LUN from a Snapshot copy, you can enable and disable access to the Snapshot copy directory using the **-snapdir-access** option of the **volume modify** command.

Steps

1. Check the Snapshot directory access status:

```
`volume show -vserver _SVM_name_ -volume _vol_name_ -fields snapdir-access`
```

Example:

```
clus1::> volume show -vserver vs0 -volume vol1 -fields snapdir-access
vserver volume snapdir-access
-----
vs0      vol1    false
```

2. Enable or disable the Snapshot copy directory access:

```
volume modify -volume vol_name -snapdir-access true|false
```

The following example enables Snapshot copy directory access on vol1:

```
clus1::> volume modify -volume vol1 -snapdir-access true
Volume modify successful on volume vol1 of Vserver vs0.
```

= Restore a single file from a Snapshot copy

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

You can use the `volume snapshot restore-file` command to restore a single file or LUN from a Snapshot copy. You can restore the file to a different location in the parent read-write volume if you do not want to replace an existing file.

About this task

If you are restoring an existing LUN, a LUN clone is created and backed up in the form of a Snapshot copy. During the restore operation, you can read to and write from the LUN.

Files with streams are restored by default.

Steps

1. List the Snapshot copies in a volume:

```
volume snapshot show -vserver SVM -volume volume
```

For complete command syntax, see the man page.

The following example shows the Snapshot copies in `vol1`:

```
clus1::> volume snapshot show -vserver vs1 -volume vol1

Vserver Volume Snapshot State Size Total% Used%
----- ----- -----
vs1 vol1 hourly.2013-01-25_0005 valid 224KB 0% 0%
          daily.2013-01-25_0010 valid 92KB 0% 0%
          hourly.2013-01-25_0105 valid 228KB 0% 0%
          hourly.2013-01-25_0205 valid 236KB 0% 0%
          hourly.2013-01-25_0305 valid 244KB 0% 0%
          hourly.2013-01-25_0405 valid 244KB 0% 0%
          hourly.2013-01-25_0505 valid 244KB 0% 0%
```

7 entries were displayed.

2. Restore a file from a Snapshot copy:

```
volume snapshot restore-file -vserver SVM -volume volume -snapshot snapshot
-path file_path -restore-path destination_path
```

For complete command syntax, see the man page.

The following example restores the file myfile.txt:

```
cluster1::> volume snapshot restore-file -vserver vs0 -volume vol1  
-snapshot daily.2013-01-25_0010 -path /myfile.txt
```

= Restore part of a file from a Snapshot copy

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use the `volume snapshot partial-restore-file` command to restore a range of data from a Snapshot copy to a LUN or to an NFS or SMB container file, assuming you know the starting byte offset of the data and the byte count. You might use this command to restore one of the databases on a host that stores multiple databases in the same LUN.

Steps

1. List the Snapshot copies in a volume:

```
volume snapshot show -vserver SVM -volume volume
```

For complete command syntax, see the man page.

The following example shows the Snapshot copies in vol1:

```
clus1::> volume snapshot show -vserver vs1 -volume vol1
```

Vserver	Volume	Snapshot	State	Size	Total%	Used%
vs1	vol1	hourly.2013-01-25_0005	valid	224KB	0%	0%
		daily.2013-01-25_0010	valid	92KB	0%	0%
		hourly.2013-01-25_0105	valid	228KB	0%	0%
		hourly.2013-01-25_0205	valid	236KB	0%	0%
		hourly.2013-01-25_0305	valid	244KB	0%	0%
		hourly.2013-01-25_0405	valid	244KB	0%	0%
		hourly.2013-01-25_0505	valid	244KB	0%	0%

7 entries were displayed.

2. Restore part of a file from a Snapshot copy:

```
volume snapshot partial-restore-file -vserver SVM -volume volume -snapshot  
snapshot -path file_path -start-byte starting_byte -byte-count byte_count
```

The starting byte offset and byte count must be multiples of 4,096.

The following example restores the first 4,096 bytes of the file myfile.txt:

```
cluster1::> volume snapshot partial-restore-file -vserver vs0  
-volume vol1 -snapshot daily.2013-01-25_0010 -path /myfile.txt  
-start-byte 0 -byte-count 4096
```

= Restore the contents of a volume from a Snapshot copy

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use the `volume snapshot restore` command to restore the contents of a volume from a Snapshot copy.

About this task

If the volume has SnapMirror relationships, manually replicate all mirror copies of the volume immediately after you restore from a Snapshot copy. Not doing so can result in unusable mirror copies that must be deleted and recreated.

Steps

1. List the Snapshot copies in a volume:

```
volume snapshot show -vserver SVM -volume volume
```

For complete command syntax, see the man page.

The following example shows the Snapshot copies in vol1:

```
clus1::> volume snapshot show -vserver vs1 -volume vol1  
  
Vserver Volume Snapshot State Size Total% Used%  
----- ----- ----- ----- ----- -----  
vs1 vol1 hourly.2013-01-25_0005 valid 224KB 0% 0%  
daily.2013-01-25_0010 valid 92KB 0% 0%  
hourly.2013-01-25_0105 valid 228KB 0% 0%  
hourly.2013-01-25_0205 valid 236KB 0% 0%  
hourly.2013-01-25_0305 valid 244KB 0% 0%  
hourly.2013-01-25_0405 valid 244KB 0% 0%  
hourly.2013-01-25_0505 valid 244KB 0% 0%  
  
7 entries were displayed.
```

2. Restore the contents of a volume from a Snapshot copy:

```
volume snapshot restore -vserver SVM -volume volume -snapshot snapshot
```

For complete command syntax, see the man page.

The following example restores the contents of `vol1`:

```
cluster1::> volume snapshot restore -vserver vs0 -volume vol1  
-snapshot daily.2013-01-25_0010
```

= SnapMirror volume replication

= About SnapMirror volume replication

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Traditionally, ONTAP replication technologies served the need for disaster recovery (DR) and data archiving. In ONTAP 9.3, these technologies were combined in a way that allows you to configure disaster recovery and archiving on the same destination volume.

= Asynchronous SnapMirror disaster recovery basics

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

SnapMirror is disaster recovery technology, designed for failover from primary storage to secondary storage at a geographically remote site. As its name implies, SnapMirror creates a replica, or *mirror*, of your working data in secondary storage from which you can continue to serve data in the event of a catastrophe at the primary site.

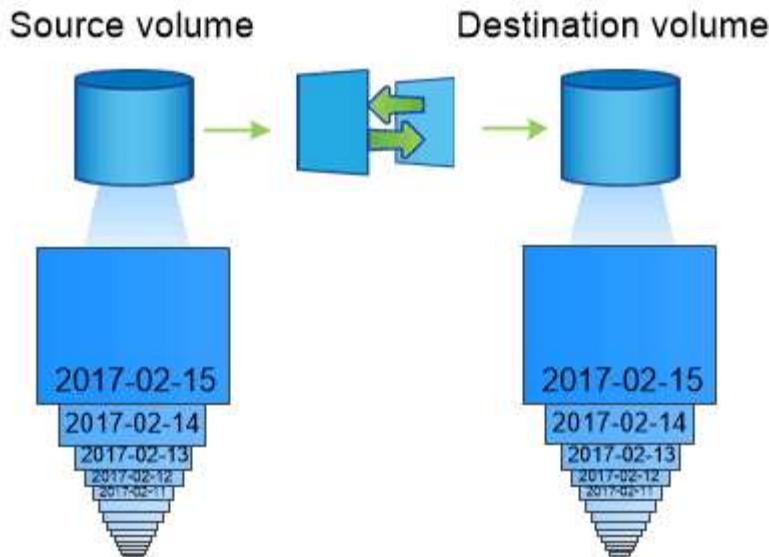

If the primary site is still available to serve data, you can simply transfer any needed data back to it, and not serve clients from the mirror at all. As the failover use case implies, the controllers on the secondary system should be equivalent or nearly equivalent to the controllers on the primary system to serve data efficiently from mirrored storage.

== Data protection relationships

Data is mirrored at the volume level. The relationship between the source volume in primary storage and the destination volume in secondary storage is called a *data protection relationship*. The clusters in which the volumes reside and the SVMs that serve data from the volumes must be *peered*. A peer relationship enables clusters and SVMs to exchange data securely.

Cluster and SVM peering

The figure below illustrates SnapMirror data protection relationships.

A SnapMirror data protection relationship typically mirrors the Snapshot copies available on the source volume.

== Scope of data protection relationships

You can create a data protection relationship directly between volumes or between the SVMs that own the volumes. In an *SVM data protection relationship*, all or part of the SVM configuration, from NFS exports and SMB shares to RBAC, is replicated, as well as the data in the volumes that the SVM owns.

You can also use SnapMirror for two special data protection applications:

- A *load-sharing mirror* copy of the SVM root volume ensures that data remains accessible in the event of a node outage or failover.
- A data protection relationship between *SnapLock volumes* lets you replicate WORM files to secondary storage.

[Archive and compliance using SnapLock technology](#)

== How SnapMirror data protection relationships are initialized

The first time you invoke SnapMirror, it performs a *baseline transfer* from the source volume to the destination volume. The *SnapMirror policy* for the relationship defines the contents of the baseline and any updates.

A baseline transfer under the default SnapMirror policy `MirrorAllSnapshots` involves the following steps:

- Make a Snapshot copy of the source volume.
- Transfer the Snapshot copy and all the data blocks it references to the destination volume.
- Transfer the remaining, less recent Snapshot copies on the source volume to the destination volume for use in case the “active” mirror is corrupted.

== How SnapMirror data protection relationships are updated

Updates are asynchronous, following the schedule you configure. Retention mirrors the Snapshot policy

on the source.

At each update under the `MirrorAllSnapshots` policy, SnapMirror creates a Snapshot copy of the source volume and transfers that Snapshot copy and any Snapshot copies that have been made since the last update. In the following output from the `snapmirror policy show` command for the `MirrorAllSnapshots` policy, note the following:

- Create Snapshot is “true”, indicating that `MirrorAllSnapshots` creates a Snapshot copy when SnapMirror updates the relationship.
- `MirrorAllSnapshots` has rules “`sm_created`” and “`all_source_snapshots`”, indicating that both the Snapshot copy created by SnapMirror and any Snapshot copies that have been made since the last update are transferred when SnapMirror updates the relationship.

```
cluster_dst:> snapmirror policy show -policy MirrorAllSnapshots
-instance

          Vserver: vs0
          SnapMirror Policy Name: MirrorAllSnapshots
          SnapMirror Policy Type: async-mirror
          Policy Owner: cluster-admin
          Tries Limit: 8
          Transfer Priority: normal
          Ignore accesstime Enabled: false
          Transfer Restartability: always
          Network Compression Enabled: false
          Create Snapshot: true
          Comment: Asynchronous SnapMirror policy for
mirroring all snapshots
                                      and the latest active file system.

          Total Number of Rules: 2
          Total Keep: 2
          Rules: SnapMirror Label      Keep  Preserve Warn
Schedule Prefix
          -----  -----
          -----  -----
          -           sm_created        1   false    0
          -           all_source_snapshots 1   false    0
          -
```

== MirrorLatest policy

The preconfigured `MirrorLatest` policy works exactly the same way as `MirrorAllSnapshots`, except that only the Snapshot copy created by SnapMirror is transferred at initialization and update.

	Rules: SnapMirror Label	Keep	Preserve	Warn
Schedule Prefix	-----	---	-----	-----
-	sm_created	1	false	0
-				

= SnapMirror Synchronous disaster recovery basics

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Beginning with ONTAP 9.5, SnapMirror Synchronous (SM-S) technology is supported on all FAS and AFF platforms that have at least 16 GB of memory and on all ONTAP Select platforms. SnapMirror Synchronous technology is a per-node, licensed feature that provides synchronous data replication at the volume level.

This functionality addresses the regulatory and national mandates for synchronous replication in financial, healthcare, and other regulated industries where zero data loss is required.

The limit on the number of SnapMirror Synchronous replication operations per HA pair depends on the controller model.

Platform	Number of SnapMirror Synchronous operations that are allowed per HA pair in releases earlier than ONTAP 9.9.1	Number of SnapMirror Synchronous operations that are allowed per HA pair in ONTAP 9.9.1	Number of SnapMirror Synchronous operations that are allowed per HA pair in ONTAP 9.10.1
AFF	80	160	200
FAS	40	80	80
ONTAP Select	20	40	40

== Supported features

The following feature is supported for SnapMirror Synchronous technology in ONTAP 9.10.1; provided all nodes in the source and destination cluster are running ONTAP 9.10.1:

- NFSv4.2

In ONTAP 9.5 and later, SnapMirror Synchronous technology supports the NFSv3, FC, and iSCSI protocols over all networks for which the latency does not exceed 10ms.

The following features are supported for SnapMirror Synchronous technology in ONTAP 9.7:

- Replication of application-created Snapshot copies

Only the Snapshot copies with the SnapMirror label that match the rule associated with Sync or Strict Sync policy. Scheduled Snapshot copies created using a Snapshot policy are not replicated.

- FC-NVMe
- LUN clones and NVMe namespace clones

LUN clones backed by application-created Snapshot copies are also supported.

The following features are supported for SnapMirror Synchronous technology in ONTAP 9.6; provided all nodes in the source and destination cluster are running ONTAP 9.6:

- SVM DR
 - A SnapMirror Synchronous source can also be a SVM DR source, for example, a fan-out configuration with SM-S as one leg and SVM DR as the other.
 - A SnapMirror Synchronous source cannot be an SVM DR destination because SM-S does not support cascading a DP source.

You must release the synchronous relationship before performing an SVM DR flip resync in the destination cluster.

- A SnapMirror Synchronous destination cannot be an SVM DR source because SVM DR does not support replication of DP volumes.

A flip resync of the synchronous source would result in the SVM DR excluding the DP volume in the destination cluster.

- NFSv4.0 and NFSv4.1
- SMB 2.0 or later
- Mixed protocol access(NFSv3 and SMB)
- Antivirus on the primary volume of the SnapMirror Synchronous relationship
- Hard or soft quotas on the primary volume of the SnapMirror Synchronous relationship

The quota rules are not replicated to the destination; therefore, the quota database is not replicated to the destination.

- FPolicy on the primary volume of the SnapMirror Synchronous relationship
- SnapMirror Synchronous mirror-mirror cascade

The relationship from the destination volume of the SnapMirror Synchronous relationship must be an asynchronous SnapMirror relationship.

- Timestamp parity between source and destination volumes for NAS

If you have upgraded from ONTAP 9.5 to ONTAP 9.6, the timestamp is replicated only for any new and modified files in the source volume. The timestamp of existing files in the source volume is not synchronized.

- Removal of high metadata operation frequency limitation
- Security for sensitive data in-transit using TLS 1.2 encryption
- Clone autodelete

== Unsupported features

The following features are not supported with Synchronous SnapMirror relationships:

- MCC
- SFMoD
- SFCoD
- VVol
- AppDM
- Mixed SAN and NAS access

The primary volume of a SnapMirror Synchronous relationship can either serve NAS data or SAN data. Both SAN and NAS access from the primary volume of a SnapMirror Synchronous relationship is not supported.

- Mixed SAN and NVMe access

LUNs and NVMe namespaces are not supported on the same volume or SVM.

- SnapLock volumes
- FlexGroup volumes
- FlexCache volumes
- SnapRestore
- DP_Optimized (DPO) systems
- Tape backup or restore using dump and SMTape on the destination volume
- Tape based restore to the source volume
- Throughput floor (QoS Min) for source volumes
- In a fan-out configuration, only one relationship can be a SnapMirror Synchronous relationship; all the other relationships from the source volume must be asynchronous SnapMirror relationships.
- Global throttling

== Modes of operation

SnapMirror Synchronous has two modes of operation based on the type of the SnapMirror policy used:

- **Sync mode**

In Sync mode, an I/O to primary storage is first replicated to secondary storage. Then the I/O is written to primary storage, and acknowledgment is sent to the application that issued the I/O. If the write to the secondary storage is not completed for any reason, the application is allowed to continue writing to the primary storage. When the error condition is corrected, SnapMirror Synchronous technology automatically resynchronizes with the secondary storage and resumes replicating from primary storage to secondary storage in Synchronous mode.

In Sync mode, RPO=0 and RTO is very low until a secondary replication failure occurs at which time RPO and RTO become indeterminate, but equal the time to repair the issue that caused secondary replication to fail and for the resync to complete.

- **StrictSync mode**

SnapMirror Synchronous can optionally operate in StrictSync mode. If the write to the secondary storage is not completed for any reason, the application I/O fails, thereby ensuring that the primary and secondary storage are identical. Application I/O to the primary resumes only after the SnapMirror relationship returns to the `InSync` status. If the primary storage fails, application I/O can be resumed on the secondary storage, after failover, with no loss of data.

In StrictSync mode RPO is always zero, and RTO is very low.

== Relationship status

The status of a SnapMirror Synchronous relationship is always in the `InSync` status during normal operation. If the SnapMirror transfer fails for any reason, the destination is not in sync with the source and can go to the `OutofSync` status.

For SnapMirror Synchronous relationships, the system automatically checks the relationship status (`InSync` or `OutofSync`) at a fixed interval. If the relationship status is `OutofSync`, ONTAP automatically triggers the auto resync process to bring back the relationship to the `InSync` status. Auto resync is triggered only if the transfer fails due to any operation, such as unplanned storage failover at source or destination or a network outage. User-initiated operations such as `snapmirror quiesce` and `snapmirror break` do not trigger auto resync.

If the relationship status becomes `OutofSync` for a SnapMirror Synchronous relationship in the StrictSync mode, all I/O operations to the primary volume are stopped. The `OutofSync` state for SnapMirror Synchronous relationship in the Sync mode is not disruptive to the primary and I/O operations are allowed on the primary volume.

= About workloads supported by StrictSync and Sync policies

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

StrictSync and Sync policies support all LUN-based applications with FC, iSCSI, and FC-NVMe protocols, as well as NFSv3 and NFSv4 protocols for enterprise applications such as databases, VMWare, quota, SMB, and so on. Beginning with ONTAP 9.6, SnapMirror Synchronous can be used for enterprise file services such as electronic design automation (EDA), home directories, and software build workloads.

In ONTAP 9.5, for a Sync policy, you need to consider a few important aspects while selecting the NFSv3 or NFSv4 workloads. The amount of data read or write operations by workloads is not a consideration, as Sync policy can handle high read or write IO workloads. In ONTAP 9.5, workloads that have excessive file creation, directory creation, file permission changes, or directory permission changes may not be suitable (these are referred to as high-metadata workloads). A typical example of a high-metadata workload is a DevOps workload in which you create multiple test files, run automation, and delete the files. Another example is parallel build workload that generate multiple temporary files during compilation. The impact of a high rate of write metadata activity is that it can cause synchronization between mirrors to temporarily break which stalls the read and write IOs from the client.

Beginning with ONTAP 9.6, these limitations are removed and SnapMirror Synchronous can be used for

enterprise file services workloads that include multiuser environments, such as home directories and software build workloads.

= Vault archiving using SnapMirror technology

:icons: font

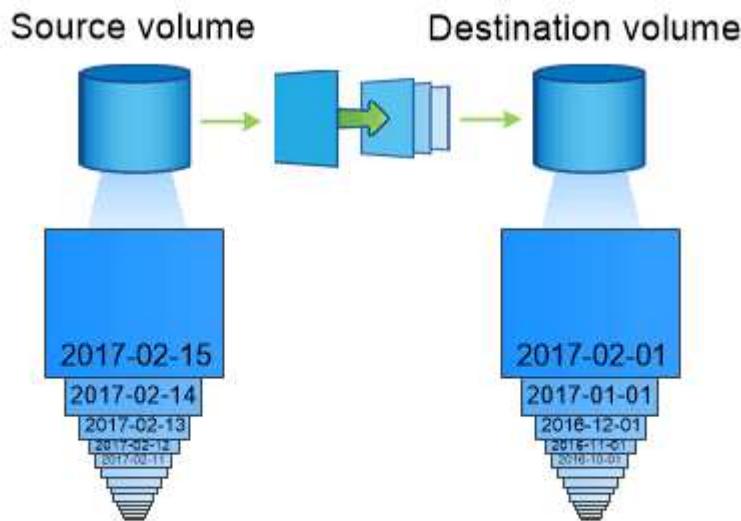

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

SnapMirror vault policies replace SnapVault technology in ONTAP 9.3 and later. You use a SnapMirror vault policy for disk-to-disk Snapshot copy replication for standards compliance and other governance-related purposes. In contrast to a SnapMirror relationship, in which the destination usually contains only the Snapshot copies currently in the source volume, a vault destination typically retains point-in-time Snapshot copies created over a much longer period.

You might want to keep monthly Snapshot copies of your data over a 20-year span, for example, to comply with government accounting regulations for your business. Since there is no requirement to serve data from vault storage, you can use slower, less expensive disks on the destination system.

The figure below illustrates SnapMirror vault data protection relationships.

A SnapVault data protection relationship typically retains point-in-time Snapshot copies created over a longer period than the Snapshot copies on the source volume.

== How vault data protection relationships are initialized

The SnapMirror policy for the relationship defines the contents of the baseline and any updates.

A baseline transfer under the default vault policy XDPDefault makes a Snapshot copy of the source volume, then transfers that copy and the data blocks it references to the destination volume. Unlike SnapMirror relationships, a vault backup does not include older Snapshot copies in the baseline.

== How vault data protection relationships are updated

Updates are asynchronous, following the schedule you configure. The rules you define in the policy for the relationship identify which new Snapshot copies to include in updates and how many copies to retain. The labels defined in the policy (“monthly,” for example) must match one or more labels defined in the Snapshot policy on the source. Otherwise, replication fails.

At each update under the XDPDefault policy, SnapMirror transfers Snapshot copies that have been made since the last update, provided they have labels matching the labels defined in the policy rules. In the following output from the snapmirror policy show command for the XDPDefault policy, note the following:

- Create Snapshot is “false”, indicating that XDPDefault does not create a Snapshot copy when SnapMirror updates the relationship.
- XDPDefault has rules “daily” and “weekly”, indicating that all Snapshot copies with matching labels on the source are transferred when SnapMirror updates the relationship.

```
cluster_dst:> snapmirror policy show -policy XDPDefault -instance

          Vserver: vs0
          SnapMirror Policy Name: XDPDefault
          SnapMirror Policy Type: vault
          Policy Owner: cluster-admin
          Tries Limit: 8
          Transfer Priority: normal
          Ignore accesstime Enabled: false
          Transfer Restartability: always
          Network Compression Enabled: false
          Create Snapshot: false
          Comment: Default policy for XDP relationships with
          daily and weekly
          rules.

          Total Number of Rules: 2
          Total Keep: 59

Schedule Prefix
          -----
          -----
          daily           7   false   0
          -
          -
          weekly          52  false   0
          -
          -
```

= SnapMirror unified replication basics

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

SnapMirror unified replication allows you to configure disaster recovery and archiving on the same destination volume. When unified replication is appropriate, it offers benefits in reducing the amount of secondary storage you need, limiting the number of baseline transfers, and decreasing network traffic.

== How unified data protection relationships are initialized

As with SnapMirror, unified data protection performs a baseline transfer the first time you invoke it. The SnapMirror policy for the relationship defines the contents of the baseline and any updates.

A baseline transfer under the default unified data protection policy `MirrorAndVault` makes a Snapshot copy of the source volume, then transfers that copy and the data blocks it references to the destination volume. Like vault archiving, unified data protection does not include older Snapshot copies in the baseline.

== How unified data protection relationships are updated

At each update under the `MirrorAndVault` policy, SnapMirror creates a Snapshot copy of the source volume and transfers that Snapshot copy and any Snapshot copies that have been made since the last update, provided they have labels matching the labels defined in the Snapshot policy rules. In the following output from the `snapmirror policy show` command for the `MirrorAndVault` policy, note the following:

- `Create Snapshot` is “true”, indicating that `MirrorAndVault` creates a Snapshot copy when SnapMirror updates the relationship.
- `MirrorAndVault` has rules “`sm_created`”, “`daily`”, and “`weekly`”, indicating that both the Snapshot copy created by SnapMirror and the Snapshot copies with matching labels on the source are transferred when SnapMirror updates the relationship.

```

cluster_dst:> snapmirror policy show -policy MirrorAndVault -instance

          Vserver: vs0
          SnapMirror Policy Name: MirrorAndVault
          SnapMirror Policy Type: mirror-vault
          Policy Owner: cluster-admin
          Tries Limit: 8
          Transfer Priority: normal
          Ignore accesstime Enabled: false
          Transfer Restartability: always
          Network Compression Enabled: false
          Create Snapshot: true
          Comment: A unified Synchronous SnapMirror and
          SnapVault policy for
                           mirroring the latest file system and
          daily and weekly snapshots.
          Total Number of Rules: 3
          Total Keep: 59
          Rules: SnapMirror Label      Keep  Preserve Warn
Schedule Prefix
          -----
          -----
          sm_created           1   false   0
          -
          -
          daily                7   false   0
          -
          -
          weekly               52  false   0
          -
          -

```

== Unified7year policy

The preconfigured Unified7year policy works exactly the same way as MirrorAndVault, except that a fourth rule transfers monthly Snapshot copies and retains them for seven years.

Schedule Prefix	Rules: SnapMirror Label	Keep	Preserve	Warn
-	sm_created	1	false	0
-	daily	7	false	0
-	weekly	52	false	0
-	monthly	84	false	0
-	-	-	-	-

== Protect against possible data corruption

Unified replication limits the contents of the baseline transfer to the Snapshot copy created by SnapMirror at initialization. At each update, SnapMirror creates another Snapshot copy of the source and transfers that Snapshot copy and any new Snapshot copies that have labels matching the labels defined in the Snapshot policy rules.

You can protect against the possibility that an updated Snapshot copy is corrupted by creating a copy of the last transferred Snapshot copy on the destination. This “local copy” is retained regardless of the retention rules on the source, so that even if the Snapshot originally transferred by SnapMirror is no longer available on the source, a copy of it will be available on the destination.

== When to use unified data replication

You need to weigh the benefit of maintaining a full mirror against the advantages that unified replication offers in reducing the amount of secondary storage, limiting the number of baseline transfers, and decreasing network traffic.

The key factor in determining the appropriateness of unified replication is the rate of change of the active file system. A traditional mirror might be better suited to a volume holding hourly Snapshot copies of database transaction logs, for example.

= XDP replaces DP as the SnapMirror default

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

Beginning with ONTAP 9.3, SnapMirror extended data protection (XDP) mode replaces SnapMirror data protection (DP) mode as the SnapMirror default.

Until ONTAP 9.3, SnapMirror invoked in DP mode and SnapMirror invoked in XDP mode used different replication engines, with different approaches to version-dependence:

- SnapMirror invoked in DP mode used a *version-dependent* replication engine in which the ONTAP version was required to be the same on primary and secondary storage:

```
cluster_dst::> snapmirror create -type DP -source-path ...
-destination-path ...
```

- SnapMirror invoked in XDP mode used a *version-flexible* replication engine that supported different ONTAP versions on primary and secondary storage:

```
cluster_dst::> snapmirror create -type XDP -source-path ...
-destination-path ...
```

With improvements in performance, the significant benefits of version-flexible SnapMirror outweigh the slight advantage in replication throughput obtained with version-dependent mode. For this reason, beginning with ONTAP 9.3, XDP mode has been made the new default, and any invocations of DP mode on the command line or in new or existing scripts are automatically converted to XDP mode.

Existing relationships are not affected. If a relationship is already of type DP, it will continue to be of type DP. Beginning with ONTAP 9.5, MirrorAndVault is the new default policy when no data protection mode is specified or when XDP mode is specified as the relationship type. The table below shows the behavior you can expect.

If you specify...	The type is...	The default policy (if you do not specify a policy) is...
DP	XDP	MirrorAllSnapshots (SnapMirror DR)
Nothing	XDP	MirrorAndVault (unified replication)
XDP	XDP	MirrorAndVault (unified replication)

As the table shows, the default policies assigned to XDP in different circumstances ensure that the conversion maintains the functional equivalence of the old types. Of course, you can use different policies as needed, including policies for unified replication:

If you specify...	And the policy is...	The result is...
DP	MirrorAllSnapshots	SnapMirror DR
	XDPDefault	SnapVault
	MirrorAndVault	Unified replication

XDP	MirrorAllSnapshots	SnapMirror DR
	XDPDefault	SnapVault
	MirrorAndVault	Unified replication

The only exceptions to conversion are as follows:

- SVM data protection relationships continue to default to DP mode in ONTAP 9.3 and earlier.
Beginning with ONTAP 9.4, SVM data protection relationships default to XDP mode.
- Root volume load-sharing data protection relationships continue to default to DP mode.
- SnapLock data protection relationships continue to default to DP mode in ONTAP 9.4 and earlier.
Beginning with ONTAP 9.5, SnapLock data protection relationships default to XDP mode.
- Explicit invocations of DP continue to default to DP mode if you set the following cluster-wide option:

```
options replication.create_data_protection_rels.enable on
```

This option is ignored if you do not explicitly invoke DP.

= When a destination volume grows automatically
 :icons: font
 :relative_path: ./data-protection/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

During a data protection mirror transfer, the destination volume grows automatically in size if the source volume has grown, provided there is available space in the aggregate that contains the volume.

This behavior occurs irrespective of any automatic growth setting on the destination. You cannot limit the volume's growth or prevent ONTAP from growing it.

By default, data protection volumes are set to the `grow_shrink` autosize mode, which enables the volume to grow or shrink in response to the amount of used space. The max-autosize for data protection volumes is equal to the maximum FlexVol size and is platform dependent. For example:

- FAS2220, default DP volume max-autosize = 60TB
- FAS6220, default DP volume max-autosize = 70TB
- FAS8200, default DP volume max-autosize = 100TB

For more information, see [NetApp Hardware Universe](#).

= Fan-out and cascade data protection deployments
 :icons: font
 :relative_path: ./data-protection/

You can use a *fan-out* deployment to extend data protection to multiple secondary systems. You can use a *cascade* deployment to extend data protection to tertiary systems.

Both fan-out and cascade deployments support any combination of SnapMirror DR, SnapVault, or unified replication; however, SnapMirror Synchronous relationships (supported beginning with ONTAP 9.5) support only fan-out deployments with one or more asynchronous SnapMirror relationships and do not support cascade deployments. Only one relationship in the fan-out configuration can be a SnapMirror Synchronous relationship, all the other relationships from the source volume must be asynchronous SnapMirror relationships.

You can use a *fan-in* deployment to create data protection relationships between multiple primary systems and a single secondary system. Each relationship must use a different volume on the secondary system.

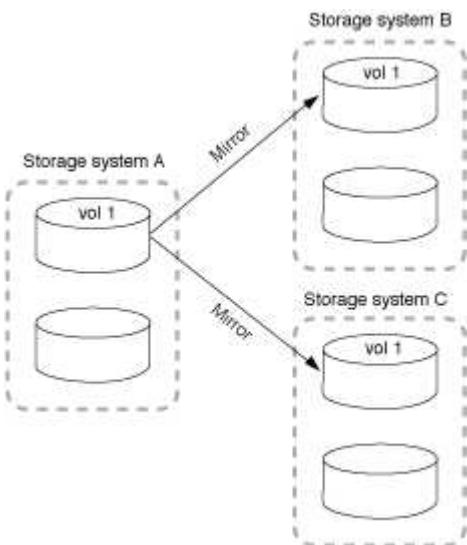

You should be aware that volumes that are part of a fan-out or cascade configuration can take longer to resynchronize. It is not uncommon to see the SnapMirror relationship reporting the status "preparing" for an extended time period.

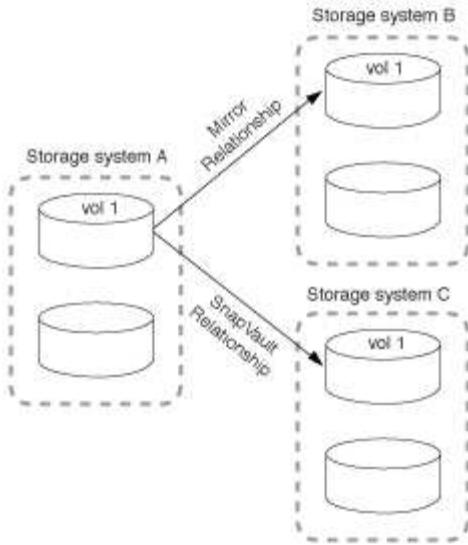

== How fan-out deployments work

SnapMirror supports *multiple-mirrors* and *mirror-vault* fan-out deployments.

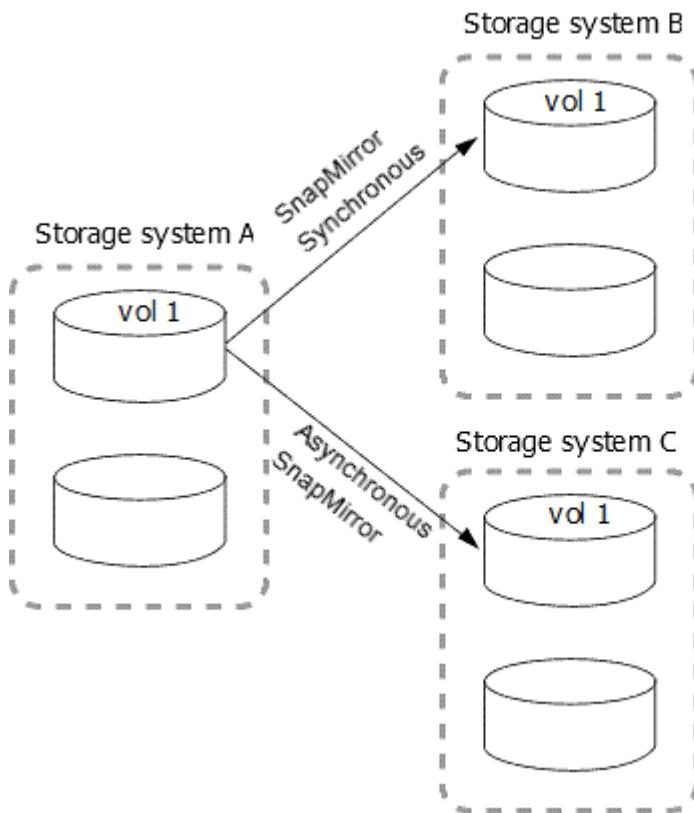

A multiple-mirrors fan-out deployment consists of a source volume that has a mirror relationship to multiple secondary volumes.

A mirror-vault fan-out deployment consists of a source volume that has a mirror relationship to a secondary volume and a SnapVault relationship to a different secondary volume.

Beginning with ONTAP 9.5, you can have fan-out deployments with SnapMirror Synchronous relationships; however, only one relationship in the fan-out configuration can be a SnapMirror Synchronous relationship, all the other relationships from the source volume must be asynchronous SnapMirror relationships.

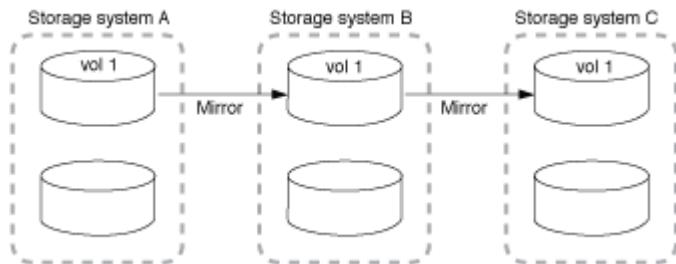

== How cascade deployments work

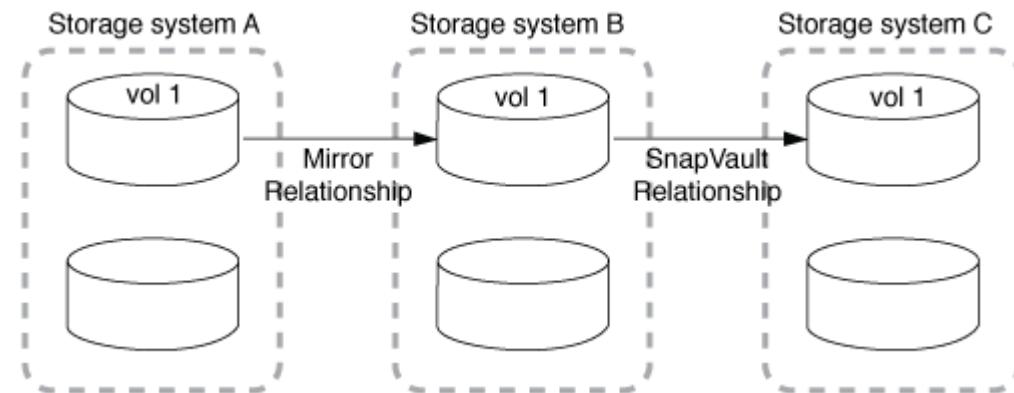

SnapMirror supports *mirror-mirror*, *mirror-vault*, *vault-mirror*, and *vault-vault* cascade deployments.

A mirror-mirror cascade deployment consists of a chain of relationships in which a source volume is mirrored to a secondary volume, and the secondary volume is mirrored to a tertiary volume. If the secondary volume becomes unavailable, you can synchronize the relationship between the primary and tertiary volumes without performing a new baseline transfer.

Beginning with ONTAP 9.6, SnapMirror Synchronous relationships are supported in a mirror-mirror cascade deployment. Only the primary and secondary volumes can be in a SnapMirror Synchronous relationship. The relationship between the secondary volumes and tertiary volumes must be asynchronous.

A mirror-vault cascade deployment consists of a chain of relationships in which a source volume is mirrored to a secondary volume, and the secondary volume is vaulted to a tertiary volume.

Vault-mirror and, beginning with ONTAP 9.2, vault-vault cascade deployments are also supported:

- A vault-mirror cascade deployment consists of a chain of relationships in which a source volume is vaulted to a secondary volume, and the secondary volume is mirrored to a tertiary volume.
- (Beginning with ONTAP 9.2) A vault-vault cascade deployment consists of a chain of relationships in which a source volume is vaulted to a secondary volume, and the secondary volume is vaulted to a tertiary volume.

= SnapMirror licensing

= SnapMirror licensing overview

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Beginning with ONTAP 9.3, licensing has been simplified for replicating between ONTAP instances. In ONTAP 9 releases, the SnapMirror license supports both vault and mirror relationships. Users can now purchase a SnapMirror license to support ONTAP replication for both backup and disaster recovery use cases.

Prior to the ONTAP 9.3 release, two licenses were available to support different replication use cases. A SnapVault license was needed to configure *vault* relationships between ONTAP instances, where the DP instance could retain a higher number of Snapshot copies to support backup use cases where retention times are longer. A SnapMirror license was needed to configure *mirror* relationships between ONTAP

instances, where each ONTAP instance would maintain the same number of snapshot copies (that is, a *mirror* image) to support disaster recovery use cases where cluster failovers would be possible. Both SnapMirror and SnapVault licenses can continue to be used and supported for ONTAP 8.x and 9.x releases.

SnapVault licenses continue to function and are supported for both ONTAP 8.x and 9.x releases, but they are no longer being sold. The SnapMirror license continues to be available and can be used in place of SnapVault and can be used for both mirror and vault configurations.

For ONTAP asynchronous replication, beginning with ONTAP 9.3 a single unified replication engine is used to configure extended data protection mode (XDP) policies, where the SnapMirror license can be configured for a mirror policy, a vault policy, or a mirror-vault policy. A SnapMirror license is required on both the source and destination clusters. A SnapVault license is not required if a SnapMirror license is already installed.

Data protection configuration limits are determined using several factors, including your ONTAP version, hardware platform, and the licenses installed. For more information, see [Hardware Universe](#).

== SnapMirror Synchronous license

Beginning with ONTAP 9.5, SnapMirror Synchronous relationships are supported. You require the following licenses for creating a SnapMirror Synchronous relationship:

- The SnapMirror Synchronous license is required on both the source cluster and the destination cluster.

The SnapMirror Synchronous license is enabled with either the Premium bundle or the Data Protection bundle.

If your system was purchased before June 2019 with a Premium or Flash Bundle, you can download a NetApp master key to get the required SnapMirror Synchronous license from the NetApp Support Site: [Master License Keys](#)

- The SnapMirror license is required on both the source cluster and the destination cluster.

== SnapMirror Cloud license

Beginning with ONTAP 9.8, the SnapMirror Cloud license provides asynchronous replication of Snapshot copies from ONTAP instances to object storage endpoints. Replication targets can be configured using both on-premises object stores as well as S3 and S3-compatible public cloud object storage services. SnapMirror Cloud relationships are supported from ONTAP systems to pre-qualified object storage targets. ONTAP 9.8 approved object storage targets include ONTAP S3, StorageGRID, AWS S3 Standard, S3 Standard-IA, and S3 One Zone-IA, Microsoft Azure Blob Premium, Hot and Cool, and GCP Standard and Nearline storage.

SnapMirror Cloud is not available as a standalone license and is available only with purchase of the Hybrid Cloud Bundle. Beginning with ONTAP 9.8, the Hybrid Cloud Bundle includes licenses for both SnapMirror Cloud and FabricPool. Similarly, the SnapMirror license is not available as a standalone license and is available only with purchase of the Data Protection Bundle.

You require the following licenses for creating a SnapMirror Cloud relationship:

- Both a SnapMirror license (purchased through Data Protection Bundle, or through Premium Bundle) and a SnapMirror Cloud license (purchased through Hybrid Cloud Bundle) is replicating directly to the object store endpoint.

- When configuring a multi-policy replication workflow (for example, Disk-to-Disk-to-Cloud), a SnapMirror license is required on all ONTAP instances, while the SnapMirror Cloud license is only required for the source cluster which is replicating directly to the object storage endpoint.

SnapMirror Cloud is an end user license which can be purchased from NetApp or from an approved NetApp reseller partner. The SnapMirror Cloud license provides end user entitlement but does not enable asynchronous ONTAP to object storage replication. To invoke ONTAP APIs for SnapMirror Cloud, a unique API key from an authorized application is required. Authorized and licensed applications used to orchestrate SnapMirror Cloud replication include System Manager, and are also available from multiple third-party application providers. These authorized applications will embed the unique API key to invoke ONTAP APIs. A combination of the SnapMirror Cloud end user license and an authorized third-party backup application is required to orchestrate and enable SnapMirror Cloud replication.

Beginning with ONTAP 9.9.1, you can use System Manager for SnapMirror Cloud replication. For more information, see [Back up to the cloud](#).

A list of authorized SnapMirror Cloud third-party applications is published on the NetApp web site.

== Data Protection Bundle

Beginning with ONTAP 9.1, new ONTAP data protection features were packaged with the FAS8200 as part of a solution called the Data Protection Bundle. This new hardware and software bundle included a new DP_Optimized (DPO) license that provided unique ONTAP features for secondary workloads. With the introduction of ONTAP 9.3 the DPO license increased the number of volumes per node from 1,000 to 1,500. Also introduced with ONTAP 9.3 were new configurations of the Data Protection Bundle based on configurations of FAS2620.

The DPO license was specifically designed for ONTAP clusters that were to be dedicated as secondary targets for SnapMirror replication. In addition to increasing the maximum volumes per node on the DPO controller, the DPO license also modified controller QoS settings to support greater replication traffic at the expense of application I/O. For this reason, the DPO license should never be installed on a cluster that supports application I/O, as application performance would be impacted. Later, Data Protection Bundles based on the FAS8200 and FAS2620 were offered as a solution and included programmatic free licenses based on the customer environment. When purchasing the solution bundles, free SnapMirror licenses would be provided for select older clusters which replicated to the DPO secondary. While the DPO license is needed on the Data Protection solution cluster, primary clusters from the following platform list would be provided free SnapMirror licenses. Primary clusters not included in this list would require purchase of SnapMirror licenses.

- FAS2200 Series
- FAS3000 Series
- FAS6000 Series
- FAS8000 Series

== Data Protection Optimized (DPO) License

Data Protection hardware and software solution bundles introduced with ONTAP 9.1 and 9.3 were based on FAS8200 and FAS2620 only. As these platforms matured and new platforms were introduced new requests to support ONTAP features for secondary replication use cases increased. As a result, a new standalone DPO license was introduced in November 2018 with ONTAP 9.5 release.

The standalone DPO license was supported on both FAS and AFF platforms and could be purchased pre-configured with new clusters or added to deployed clusters as a software upgrade in the field. Because these new DPO licenses were not part of a hardware and software solution bundle they carried a lower

price and free SnapMirror licenses for primary clusters were not provided. Secondary clusters configured with the a la carte DPO license must also purchase a SnapMirror license, and all primary clusters replicating to the DPO secondary cluster must purchase a SnapMirror license.

Additional ONTAP features were delivered with the DPO across multiple ONTAP releases.

Feature	9.3	9.4	9.5	9.6	9.7+
Max vols/node	1500	1500	1500	1500/2500	1500/2500
Max concurrent repl sessions	100	200	200	200	200
Workload bias*	client apps	Apps/SM	SnapMirror	SnapMirror	SnapMirror
Cross volume aggregate deduplication for HDD	No	Yes	Yes	Yes	Yes

- Details about priority for the SnapMirror backoff (workload bias) feature:
- Client: cluster I/O priority is set to client workloads (production apps), not SnapMirror traffic.
- Equality: SnapMirror replication requests have equal priority to I/O for production apps.
- SnapMirror: all SnapMirror I/O requests have higher priority than I/O for production apps.

Table 1: Max FlexVolumes per node across ONTAP releases

	9.3—9.5 Without DPO	9.3—9.5 With DPO	9.6 Without DPO	9.6 With DPO	9.7—9.9.1 Without DPO	9.7—9.9.1 With DPO
FAS2620	1000	1500	1000	1500	1000	1500
FAS2650	1000	1500	1000	1500	1000	1500
FAS2720	1000	1500	1000	1500	1000	1500
FAS2750	1000	1500	1000	1500	1000	1500
A200	1000	1500	1000	1500	1000	1500
A220	1000	1500	1000	1500	1000	1500
FAS8200/8300	1000	1500	1000	2500	1000	2500
A300	1000	1500	1000	2500	2500	2500

A400	1000	1500	1000	2500	2500	2500
FAS8700/900 0	1000	1500	1000	2500	1000	2500
A700	1000	1500	1000	2500	2500	2500
A700s	1000	1500	1000	2500	2500	2500
A800	1000	1500	1000	2500	2500	2500

For the latest maximum FlexVol volume support for your configuration, see [Hardware Universe](#).

== Considerations for all new DPO installations

- After it is enabled, the DPO license feature cannot be disabled or undone.
- Installation of the DPO license requires a re-boot of ONTAP or failover to enable.
- The DPO solution is intended for secondary storage workloads; application workload performance on DPO clusters may be impacted
- The DPO license is supported on a select list of NetApp storage platform models.
- DPO features vary by ONTAP release. Refer to the compatibility table for reference.

= Install a SnapMirror Cloud license

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Beginning with ONTAP 9.8, SnapMirror Cloud provides asynchronous snapshot replication from ONTAP to object storage endpoints. SnapMirror Cloud relationships can only be configured using pre-qualified third-party backup applications. To configure ONTAP to object storage replication, both SnapMirror and SnapMirror Cloud licenses are required on the ONTAP source cluster configured for replication to the object store endpoint.

About this task

The SnapMirror Cloud license is a single-instance cluster-wide license, it does not need to be installed on every node in the cluster. It is a term-based license where both term and backup capacity are enforced. In addition to this end user license, SnapMirror Cloud requires an authorized and approved backup application to configure and invoke ONTAP APIs for replication. Both SnapMirror Cloud end user license and authorized app are necessary to utilize SnapMirror Cloud replication.

SnapMirror Cloud licenses are acquired through purchase of the Hybrid Cloud Bundle, which can be purchased with 1 or 3 year terms in 1 TB increments. The Hybrid Cloud Bundle includes two licenses — one license for FabricPool and a separate license for SnapMirror Cloud. Each license has a unique serial number. Purchases of the Hybrid Cloud Bundle are based on capacity, where the purchased capacity of the Hybrid Cloud Bundle is applied to both FabricPool and SnapMirror Cloud licenses.

The Hybrid Cloud Bundle provides 10 TB of free capacity for first time orders. When purchasing the

Hybrid Cloud Bundle, the 10 TB free capacity is provided for both FabricPool and SnapMirror Cloud licenses. Subsequent orders for add-on capacity will not include the 10 TB free capacity.

SnapMirror Cloud license can be installed on the cluster using the ONTAP command line or System Manager.

Steps

1. The Hybrid Cloud Bundle includes two licenses. Download two NetApp License Files (NLF), one for the FabricPool license and a separate NLF for SnapMirror Cloud from the NetApp Support Site.

[NetApp Support](#)

2. Use System Manager to upload both FabricPool and SnapMirror Cloud NLF files to the cluster:
 - a. Click **Configuration > Licenses**.
 - b. In the **Cluster Settings** pane, click **Licenses**.
 - c. In the **Packages** window, click **Add**.
 - d. In the **Add License Packages** dialog box, click **Choose Files** to select the NLF you downloaded, and then click **Add** to upload the file to the cluster.

[NetApp Software License Search](#)

= DPO systems feature enhancements

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Beginning with ONTAP 9.6, the maximum number of FlexVol volumes supported increases when the DP_Optimized (DPO) license is installed. Beginning with ONTAP 9.4, systems with the DPO license support SnapMirror backoff, cross-volume background deduplication, cross-volume inline deduplication, use of Snapshot blocks as donors, and compaction.

Beginning with ONTAP 9.6, the maximum supported number of FlexVol volumes on secondary or data protection systems has increased, enabling you to scale up to 2,500 FlexVol volumes per node, or up to 5,000 in failover mode. The increase in FlexVol volumes is enabled with the DP_Optimized (DPO) license. A SnapMirror license is still required on both the source and destination nodes.

Beginning with ONTAP 9.4, the following feature enhancements are made to DPO systems:

- SnapMirror backoff: In DPO systems, replication traffic is given the same priority that client workloads are given.

SnapMirror backoff is disabled by default on DPO systems.

- Volume background deduplication and cross-volume background deduplication: Volume background deduplication and cross-volume background deduplication are enabled in DPO systems.

You can run the storage aggregate efficiency cross-volume-dedupe start -aggregate aggregate_name -scan-old-data true command to deduplicate the existing data. The best practice is to run the command during off-peak hours to reduce the impact on performance.

- Increased savings by using Snapshot blocks as donors: The data blocks that are not available in the active file system but are trapped in Snapshot copies are used as donors for volume deduplication.

The new data can be deduplicated with the data that was trapped in Snapshot copies, effectively sharing the Snapshot blocks as well. The increased donor space provides more savings, especially when the volume has a large number of Snapshot copies.

- Compaction: Data compaction is enabled by default on DPO volumes.

= Manage SnapMirror volume replication

= SnapMirror replication workflow

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

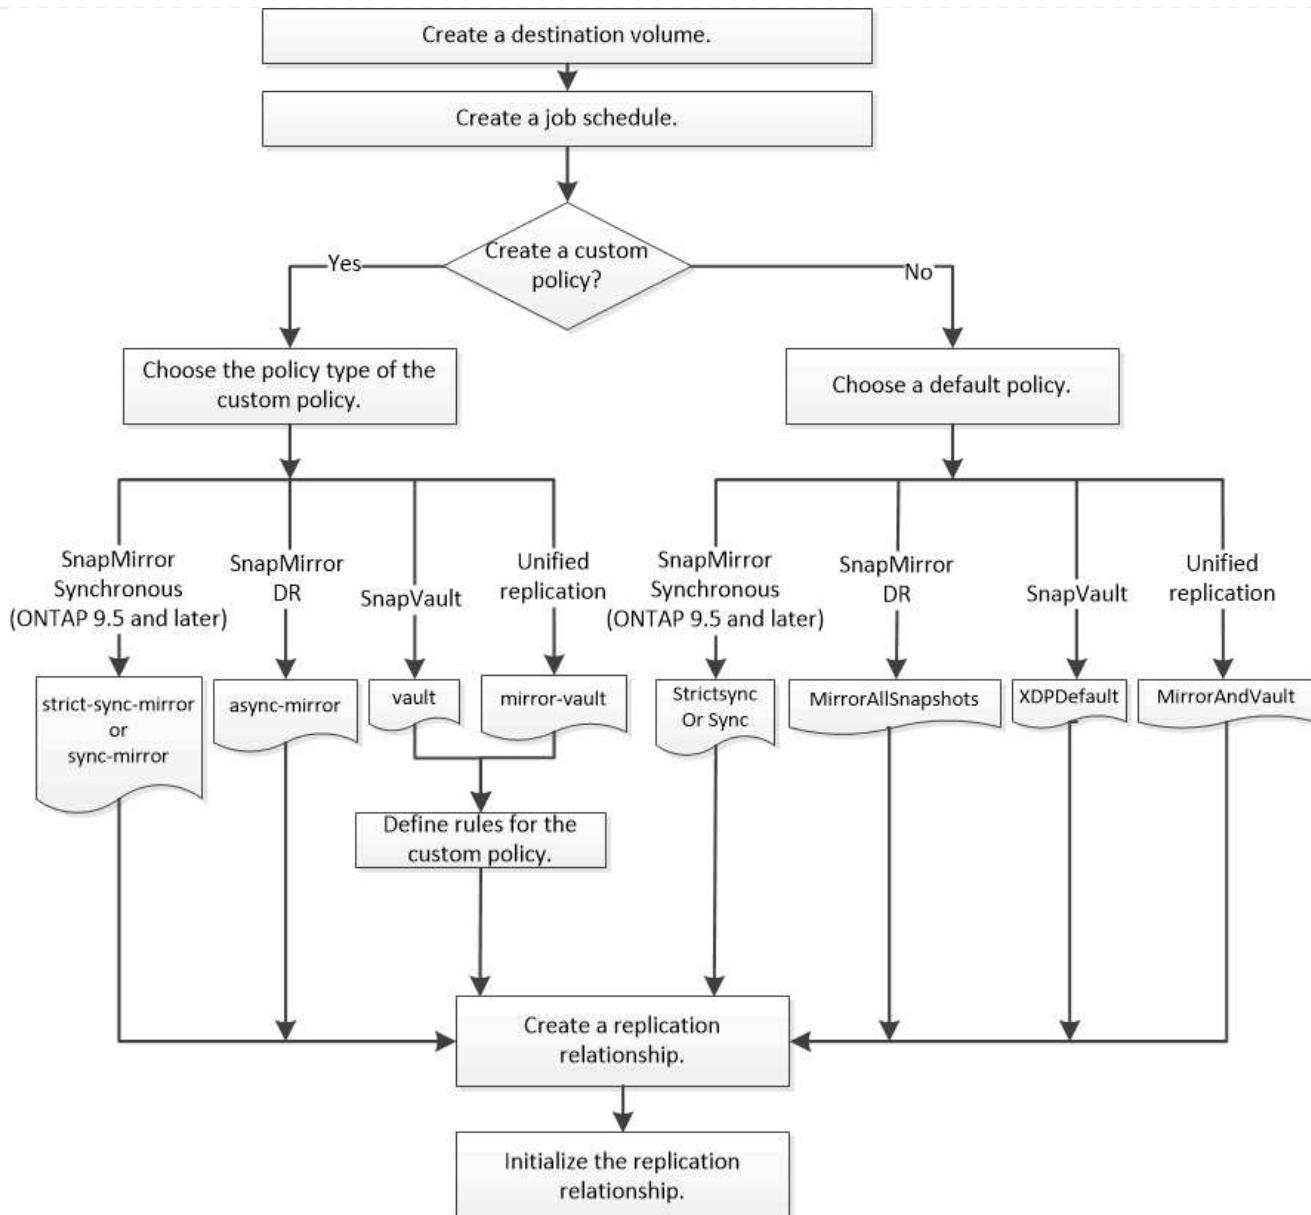

SnapMirror offers three types of data protection relationship: SnapMirror DR, archive (previously known as SnapVault), and unified replication. You can follow the same basic workflow to configure each type of relationship.

Beginning with general availability in ONTAP 9.9.1, SnapMirror Business Continuity (SM-BC) provides Zero Recovery Time Objective (Zero RTO) or Transparent Application Failover (TAF) to enable automatic failover of business-critical applications in SAN environments. SM-BC is supported in a configuration of either two AFF clusters or two All SAN Array (ASA) clusters.

[NetApp Documentation: SnapMirror Business Continuity](#)

For each type of SnapMirror data protection relationship, the workflow is the same: create a destination volume, create a job schedule, specify a policy, create and initialize the relationship.

Beginning with ONTAP 9.3, you can use the `snapmirror protect` command to configure a data protection relationship in a single step. Even if you use `snapmirror protect`, you need to understand each step in the workflow.

= Configure a replication relationship in one step

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Beginning with ONTAP 9.3, you can use the `snapmirror protect` command to configure a data protection relationship in a single step. You specify a list of volumes to be replicated, an SVM on the destination cluster, a job schedule, and a SnapMirror policy. `snapmirror protect` does the rest.

What you'll need

- The source and destination clusters and SVMs must be peered.

Cluster and SVM peering

- The language on the destination volume must be the same as the language on the source volume.

About this task

The `snapmirror protect` command chooses an aggregate associated with the specified SVM. If no aggregate is associated with the SVM, it chooses from all the aggregates in the cluster. The choice of aggregate is based on the amount of free space and the number of volumes on the aggregate.

The `snapmirror protect` command then performs the following steps:

- Creates a destination volume with an appropriate type and amount of reserved space for each volume in the list of volumes to be replicated.
- Configures a replication relationship appropriate for the policy you specify.
- Initializes the relationship.

The name of the destination volume is of the form `source_volume_name_dst`. In case of a conflict with an existing name, the command appends a number to the volume name. You can specify a prefix and/or suffix in the command options. The suffix replaces the system-supplied `dst` suffix.

In ONTAP 9.3 and earlier, a destination volume can contain up to 251 Snapshot copies. In ONTAP 9.4 and later, a destination volume can contain up to 1019 Snapshot copies.

Initialization can be time-consuming. `snapmirror protect` does not wait for initialization to complete before the job finishes. For this reason, you should use the `snapmirror show` command rather than the `job show` command to determine when initialization is complete.

Beginning with ONTAP 9.5, SnapMirror Synchronous relationships can be created by using the `snapmirror protect` command.

Step

1. Create and initialize a replication relationship in one step:

```
snapmirror protect -path-list SVM:volume|cluster://SVM/volume, ...
-destination-vserver destination_SVM -policy policy -schedule schedule
-auto-initialize true|false -destination-volume-prefix prefix -destination
-volume-suffix suffix
```

You must run this command from the destination SVM or the destination cluster. The `-auto-initialize` option defaults to “true”.

The following example creates and initializes a SnapMirror DR relationship using the default `MirrorAllSnapshots` policy:

```
cluster_dst::> snapmirror protect -path-list svm1:volA, svm1:volB
-destination-vserver svm_backup -policy MirrorAllSnapshots -schedule
replication_daily
```

You can use a custom policy if you prefer. For more information, see [Creating a custom replication policy](#).

The following example creates and initializes a SnapVault relationship using the default `XDPDefault`

policy:

```
cluster_dst::> snapmirror protect -path-list svm1:volA, svm1:volB  
-destination-vserver svm_backup -policy XDPDefault -schedule  
replication_daily
```

The following example creates and initializes a unified replication relationship using the default MirrorAndVault policy:

```
cluster_dst::> snapmirror protect -path-list svm1:volA, svm1:volB  
-destination-vserver svm_backup -policy MirrorAndVault
```

The following example creates and initializes a SnapMirror Synchronous relationship using the default Sync policy:

```
cluster_dst::> snapmirror protect -path-list svm1:volA, svm1:volB  
-destination-vserver svm_sync -policy Sync
```

For SnapVault and unified replication policies, you might find it useful to define a schedule for creating a copy of the last transferred Snapshot copy on the destination. For more information, see [Defining a schedule for creating a local copy on the destination](#).

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

= Configure a replication relationship one step at a time

= Create a destination volume

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use the `volume create` command on the destination to create a destination volume. The destination volume should be the same or greater in size than the source volume.

Step

1. Create a destination volume:

```
volume create -vserver SVM -volume volume -aggregate aggregate -type DP  
-size size
```

For complete command syntax, see the man page.

The following example creates a 2-GB destination volume named `volA_dst`:

```
cluster_dst::> volume create -vserver SVM_backup -volume volA_dst  
-aggregate node01_aggr -type DP -size 2GB
```

= Create a replication job schedule

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use the `job schedule cron create` command to create a replication job schedule. The job schedule determines when SnapMirror automatically updates the data protection relationship to which the schedule is assigned.

About this task

You assign a job schedule when you create a data protection relationship. If you do not assign a job schedule, you must update the relationship manually.

Step

1. Create a job schedule:

```
job schedule cron create -name job_name -month month -dayofweek day_of_week  
-day day_of_month -hour hour -minute minute
```

For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the week, and hour, respectively.

Beginning with ONTAP 9.10.1, you can include the Vserver for your job schedule:

```
job schedule cron create -name job_name -vserver Vserver_name -month month  
-dayofweek day_of_week -day day_of_month -hour hour -minute minute
```

The following example creates a job schedule named `my_weekly` that runs on Saturdays at 3:00 a.m.:

```
cluster_dst::> job schedule cron create -name my_weekly -dayofweek  
"Saturday" -hour 3 -minute 0
```

= Customize a replication policy

= Create a custom replication policy

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can create a custom replication policy if the default policy for a relationship is not suitable. You might want to compress data in a network transfer, for example, or modify the number of attempts SnapMirror makes to transfer Snapshot copies.

You can use a default or custom policy when you create a replication relationship. For a custom archive (formerly SnapVault) or unified replication policy, you must define one or more *rules* that determine which Snapshot copies are transferred during initialization and update. You might also want to define a schedule for creating local Snapshot copies on the destination.

The *policy type* of the replication policy determines the type of relationship it supports. The table below shows the available policy types.

Policy type	Relationship type
async-mirror	SnapMirror DR
vault	SnapVault
mirror-vault	Unified replication
strict-sync-mirror	SnapMirror Synchronous in the StrictSync mode (supported beginning with ONTAP 9.5)
sync-mirror	SnapMirror Synchronous in the Sync mode (supported beginning with ONTAP 9.5)

When you create a custom replication policy, it is a good idea to model the policy after a default policy.

Step

1. Create a custom replication policy:

```
snapmirror policy create -vserver SVM -policy policy -type async-mirror|vault|mirror-vault|strict-sync-mirror|sync-mirror -comment comment -tries transfer_tries -transfer-priority low|normal -is-network-compression -enabled true|false
```

For complete command syntax, see the man page.

Beginning with ONTAP 9.5, you can specify the schedule for creating a common Snapshot copy schedule for SnapMirror Synchronous relationships by using the `-common-snapshot-schedule` parameter. By default, the common Snapshot copy schedule for SnapMirror Synchronous relationships is one hour. You can specify a value from 30 minutes to two hours for the Snapshot copy schedule for SnapMirror Synchronous relationships.

The following example creates a custom replication policy for SnapMirror DR that enables network compression for data transfers:

```
cluster_dst::> snapmirror policy create -vserver svml -policy DR_compressed -type async-mirror -comment "DR with network compression enabled" -is-network-compression-enabled true
```

The following example creates a custom replication policy for SnapVault:

```
cluster_dst::> snapmirror policy create -vserver svml -policy  
my_snapvault -type vault
```

The following example creates a custom replication policy for unified replication:

```
cluster_dst::> snapmirror policy create -vserver svml -policy  
my_unified -type mirror-vault
```

The following example creates a custom replication policy for SnapMirror Synchronous relationship in the StrictSync mode:

```
cluster_dst::> snapmirror policy create -vserver svml -policy  
my_strictsync -type strict-sync-mirror -common-snapshot-schedule  
my_sync_schedule
```

After you finish

For “vault” and “mirror-vault” policy types, you must define rules that determine which Snapshot copies are transferred during initialization and update.

Use the `snapmirror policy show` command to verify that the SnapMirror policy was created. For complete command syntax, see the man page.

= Define a rule for a policy

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

For custom policies with the “vault” or “mirror-vault” policy type, you must define at least one rule that determines which Snapshot copies are transferred during initialization and update. You can also define rules for default policies with the “vault” or “mirror-vault” policy type.

About this task

Every policy with the “vault” or “mirror-vault” policy type must have a rule that specifies which Snapshot copies to replicate. The rule “bi-monthly”, for example, indicates that only Snapshot copies assigned the SnapMirror label “bi-monthly” should be replicated. You specify the SnapMirror label when you configure the Snapshot policy on the source.

Each policy type is associated with one or more system-defined rules. These rules are automatically assigned to a policy when you specify its policy type. The table below shows the system-defined rules.

System-defined rule	Used in policy types	Result
sm_created	async-mirror, mirror-vault, Sync, StrictSync	A Snapshot copy created by SnapMirror is transferred on initialization and update.

all_source_snapshots	async-mirror	New Snapshot copies on the source are transferred on initialization and update.
daily	vault,mirror-vault	New Snapshot copies on the source with the SnapMirror label “daily” are transferred on initialization and update.
weekly	vault,mirror-vault	New Snapshot copies on the source with the SnapMirror label “weekly” are transferred on initialization and update.
monthly	mirror-vault	New Snapshot copies on the source with the SnapMirror label “monthly” are transferred on initialization and update.
app_consistent	Sync, StrictSync	Snapshot copies with the SnapMirror label “app_consistent” on source are synchronously replicated to the destination. Supported Beginning with ONTAP 9.7.

Except for the “async-mirror” policy type, you can specify additional rules as needed, for default or custom policies. For example:

- For the default `MirrorAndVault` policy, you might create a rule called “bi-monthly” to match Snapshot copies on the source with the “bi-monthly” SnapMirror label.
- For a custom policy with the “mirror-vault” policy type, you might create a rule called “bi-weekly” to match Snapshot copies on the source with the “bi-weekly” SnapMirror label.

Step

1. Define a rule for a policy:

```
snapmirror policy add-rule -vserver SVM -policy policy_for_rule -snapmirror
-label snapmirror-label -keep retention_count
```

For complete command syntax, see the man page.

The following example adds a rule with the SnapMirror label `bi-monthly` to the default `MirrorAndVault` policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy
MirrorAndVault -snapmirror-label bi-monthly -keep 6
```

The following example adds a rule with the SnapMirror label `bi-weekly` to the custom

```
my_snapvault policy:
```

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy  
my_snapvault -snapmirror-label bi-weekly -keep 26
```

The following example adds a rule with the SnapMirror label `app_consistent` to the custom Sync policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy Sync  
-snapmirror-label app_consistent -keep 1
```

You can then replicate Snapshot copies from the source cluster that match this SnapMirror label:

```
cluster_src::> snapshot create -vserver vs1 -volume vol1 -snapshot  
snapshot1 -snapmirror-label app_consistent
```

= Define a schedule for creating a local copy on the destination

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

For SnapVault and unified replication relationships, you can protect against the possibility that an updated Snapshot copy is corrupted by creating a copy of the last transferred Snapshot copy on the destination. This “local copy” is retained regardless of the retention rules on the source, so that even if the Snapshot originally transferred by SnapMirror is no longer available on the source, a copy of it will be available on the destination.

About this task

You specify the schedule for creating a local copy in the `-schedule` option of the `snapmirror policy add-rule` command.

Step

1. Define a schedule for creating a local copy on the destination:

```
snapmirror policy add-rule -vserver SVM -policy policy_for_rule -snapmirror  
-label snapmirror-label -schedule schedule
```

For complete command syntax, see the man page. For an example of how to create a job schedule, see [Creating a replication job schedule](#).

The following example adds a schedule for creating a local copy to the default `MirrorAndVault` policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy  
MirrorAndVault -snapmirror-label my_monthly -schedule my_monthly
```

The following example adds a schedule for creating a local copy to the custom `my_unified` policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy  
my_unified -snapmirror-label my_monthly -schedule my_monthly
```

= Create a replication relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

The relationship between the source volume in primary storage and the destination volume in secondary storage is called a *data protection relationship*. You can use the `snapmirror create` command to create SnapMirror DR, SnapVault, or unified replication data protection relationships.

What you'll need

- The source and destination clusters and SVMs must be peered.

[Cluster and SVM peering](#)

- The language on the destination volume must be the same as the language on the source volume.

About this task

Until ONTAP 9.3, SnapMirror invoked in DP mode and SnapMirror invoked in XDP mode used different replication engines, with different approaches to version-dependence:

- SnapMirror invoked in DP mode used a *version-dependent* replication engine in which the ONTAP version was required to be the same on primary and secondary storage:

```
cluster_dst::> snapmirror create -type DP -source-path ...  
-destination-path ...
```

- SnapMirror invoked in XDP mode used a *version-flexible* replication engine that supported different ONTAP versions on primary and secondary storage:

```
cluster_dst::> snapmirror create -type XDP -source-path ...  
-destination-path ...
```

With improvements in performance, the significant benefits of version-flexible SnapMirror outweigh the slight advantage in replication throughput obtained with version-dependent mode. For this reason, beginning with ONTAP 9.3, XDP mode has been made the new default, and any invocations of DP mode

on the command line or in new or existing scripts are automatically converted to XDP mode.

Existing relationships are not affected. If a relationship is already of type DP, it will continue to be of type DP. The table below shows the behavior you can expect.

If you specify...	The type is...	The default policy (if you do not specify a policy) is...
DP	XDP	MirrorAllSnapshots (SnapMirror DR)
Nothing	XDP	MirrorAllSnapshots (SnapMirror DR)
XDP	XDP	XDPDefault (SnapVault)

See also the examples in the procedure below.

The only exceptions to conversion are as follows:

- SVM data protection relationships continue to default to DP mode.

Specify XDP explicitly to obtain XDP mode with the default `MirrorAllSnapshots` policy.

- Load-sharing data protection relationships continue to default to DP mode.
- SnapLock data protection relationships continue to default to DP mode.
- Explicit invocations of DP continue to default to DP mode if you set the following cluster-wide option:

```
options replication.create_data_protection_rels.enable on
```

This option is ignored if you do not explicitly invoke DP.

In ONTAP 9.3 and earlier, a destination volume can contain up to 251 Snapshot copies. In ONTAP 9.4 and later, a destination volume can contain up to 1019 Snapshot copies.

Beginning with ONTAP 9.5, SnapMirror Synchronous relationships are supported.

Step

- From the destination cluster, create a replication relationship:

```
snapmirror create -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ... -type DP|XDP -schedule
schedule -policy policy
```

For complete command syntax, see the man page.

The `schedule` parameter is not applicable when creating SnapMirror Synchronous relationships.

The following example creates a SnapMirror DR relationship using the default `MirrorLatest` policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -schedule my_daily -policy  
MirrorLatest
```

The following example creates a SnapVault relationship using the default XDPDefault policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -schedule my_daily -policy  
XDPDefault
```

The following example creates a unified replication relationship using the default MirrorAndVault policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -schedule my_daily -policy  
MirrorAndVault
```

The following example creates a unified replication relationship using the custom my_unified policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -schedule my_daily -policy  
my_unified
```

The following example creates a SnapMirror Synchronous relationship using the default Sync policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -policy Sync
```

The following example creates a SnapMirror Synchronous relationship using the default StrictSync policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -policy StrictSync
```

The following example creates a SnapMirror DR relationship. With the DP type automatically converted to XDP and with no policy specified, the policy defaults to the MirrorAllSnapshots policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type DP -schedule my_daily
```

The following example creates a SnapMirror DR relationship. With no type or policy specified, the policy defaults to the `MirrorAllSnapshots` policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -schedule my_daily
```

The following example creates a SnapMirror DR relationship. With no policy specified, the policy defaults to the `XDPDefault` policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -schedule my_daily
```

The following example creates a SnapMirror Synchronous relationship with the predefined policy `SnapCenterSync`:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst -type XDP -policy SnapCenterSync
```

The predefined policy `SnapCenterSync` is of type `Sync`. This policy replicates any Snapshot copy that is created with the `snapmirror-label` of "app_consistent".

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
The redesigned System Manager (available with ONTAP 9.7 and later)	Configure mirrors and vaults
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume backup using SnapVault overview

= Initialize a replication relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

For all relationship types, initialization performs a *baseline transfer*: it makes a Snapshot copy of the source volume, then transfers that copy and all the data blocks

it references to the destination volume. Otherwise, the contents of the transfer depend on the policy.

What you'll need

The source and destination clusters and SVMs must be peered.

Cluster and SVM peering

About this task

Initialization can be time-consuming. You might want to run the baseline transfer in off-peak hours.

Beginning with ONTAP 9.5, SnapMirror Synchronous relationships are supported.

Step

1. Initialize a replication relationship:

```
snapmirror initialize -source-path SVM:volume|cluster://SVM/volume, ...
                     -destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

The following example initializes the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror initialize -source-path svm1:volA
                     -destination-path svm_backup:volA_dst
```

= Example: Configure a vault-vault cascade

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

An example will show in concrete terms how you can configure replication relationships one step at a time. You can use the vault-vault cascade deployment configured in the example to retain more than 251 Snapshot copies labeled “my-weekly”.

What you'll need

- The source and destination clusters and SVMs must be peered.
- You must be running ONTAP 9.2 or later. Vault-vault cascades are not supported in earlier ONTAP releases.

About this task

The example assumes the following:

- You have configured Snapshot copies on the source cluster with the SnapMirror labels “my-daily”, “my-weekly”, and “my-monthly”.

- You have configured destination volumes named “volA” on the secondary and tertiary destination clusters.
- You have configured replication job schedules named “my_snapvault” on the secondary and tertiary destination clusters.

The example shows how to create replication relationships based on two custom policies:

- The “snapvault_secondary” policy retains 7 daily, 52 weekly, and 180 monthly Snapshot copies on the secondary destination cluster.
- The “snapvault_tertiary policy” retains 250 weekly Snapshot copies on the tertiary destination cluster.

Steps

1. On the secondary destination cluster, create the “snapvault_secondary” policy:

```
cluster_secondary::> snapmirror policy create -policy snapvault_secondary
-type vault -comment "Policy on secondary for vault to vault cascade"
-vserver svm_secondary
```

2. On the secondary destination cluster, define the “my-daily” rule for the policy:

```
cluster_secondary::> snapmirror policy add-rule -policy snapvault_secondary
-snapmirror-label my-daily -keep 7 -vserver svm_secondary
```

3. On the secondary destination cluster, define the “my-weekly” rule for the policy:

```
cluster_secondary::> snapmirror policy add-rule -policy snapvault_secondary
-snapmirror-label my-weekly -keep 52 -vserver svm_secondary
```

4. On the secondary destination cluster, define the “my-monthly” rule for the policy:

```
cluster_secondary::> snapmirror policy add-rule -policy snapvault_secondary
-snapmirror-label my-monthly -keep 180 -vserver svm_secondary
```

5. On the secondary destination cluster, verify the policy:

```
cluster_secondary::> snapmirror policy show snapvault_secondary -instance
```

```

0 -           my-daily          7   false
0 -           my-weekly         52   false
0 -           my-monthly        180  false

```

6. On the secondary destination cluster, create the relationship with the source cluster:

```
cluster_secondary::> snapmirror create -source-path svm_primary:volA
-destination-path svm_secondary:volA -type XDP -schedule my_snapvault
-policy snapvault_secondary
```

7. On the secondary destination cluster, initialize the relationship with the source cluster:

```
cluster_secondary::> snapmirror initialize -source-path svm_primary:volA
-destination-path svm_secondary:volA
```

8. On the tertiary destination cluster, create the “snapvault_ternary” policy:

```
cluster_ternary::> snapmirror policy create -policy snapvault_ternary
-type vault -comment "Policy on tertiary for vault to vault cascade"
-vserver svm_ternary
```

9. On the tertiary destination cluster, define the “my-weekly” rule for the policy:

```
cluster_ternary::> snapmirror policy add-rule -policy snapvault_ternary
-snapmirror-label my-weekly -keep 250 -vserver svm_ternary
```

10. On the tertiary destination cluster, verify the policy:

```
cluster_ternary::> snapmirror policy show snapvault_ternary -instance
```

```
Vserver: svm_ternary
SnapMirror Policy Name: snapvault_ternary
SnapMirror Policy Type: vault
Policy Owner: cluster-admin
Tries Limit: 8
Transfer Priority: normal
Ignore accesstime Enabled: false
Transfer Restartability: always
Network Compression Enabled: false
Create Snapshot: false
Comment: Policy on tertiary for vault to vault
cascade
Total Number of Rules: 1
Total Keep: 250
Rules: SnapMirror Label      Keep  Preserve
Warn Schedule Prefix
-----  -----  -----
-----  -----
my-weekly          250  false
0  -
```

11. On the tertiary destination cluster, create the relationship with the secondary cluster:

```
cluster_ternary::> snapmirror create -source-path svm_secondary:volA
-destination-path svm_ternary:volA -type XDP -schedule my_snapvault
-policy snapvault_ternary
```

12. On the tertiary destination cluster, initialize the relationship with the secondary cluster:

```
cluster_ternary::> snapmirror initialize -source-path svm_secondary:volA
-destination-path svm_ternary:volA
```

= Convert an existing DP-type relationship to XDP

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can easily convert an existing DP-type relationship to XDP to take advantage of version-flexible SnapMirror.

About this task

- SnapMirror does not automatically convert existing DP-type relationships to XDP. To convert the relationship, you need to break and delete the existing relationship, create a new XDP relationship, and resync the relationship. For background information, see [XDP replaces DP as the SnapMirror default](#).

- When planning your conversion, you should be aware that background preparation and the data warehousing phase of an XDP SnapMirror relationship can take a long time. It is not uncommon to see the SnapMirror relationship reporting the status "preparing" for an extended time period.

After you convert a SnapMirror relationship type from DP to XDP, space-related settings, such as autosize and space guarantee are no longer replicated to the destination.

Steps

1. Quiesce the existing DP-type relationship:

```
snapmirror quiesce -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

The following example quiesces the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror quiesce -source-path svm1:volA
-destination-path svm_backup:volA_dst
```

2. Break the existing DP-type relationship:

```
snapmirror break -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

The following example breaks the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror break -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

3. Disable automatic deletion of Snapshot copies on the destination volume:

```
volume snapshot autodelete modify -vserver SVM -volume volume -enabled
false
```

The following example disables Snapshot copy autodelete on the destination volume `volA_dst`:

```
cluster_dst::> volume snapshot autodelete modify -vserver svm_backup  
-volume volA_dst -enabled false
```

4. Delete the existing DP-type relationship:

```
snapmirror delete -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

The following example deletes the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror delete -source-path svm1:volA -destination  
-path svm_backup:volA_dst
```

5. Create the new XDP-type relationship:

```
snapmirror create -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ... -type XDP -schedule  
schedule -policy policy
```

The new relationship must use the same source and destination volume. For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

The following example creates a SnapMirror DR relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup` using the default `MirrorAllSnapshots` policy:

```
cluster_dst::> snapmirror create -source-path svm1:volA -destination  
-path svm_backup:volA_dst  
-type XDP -schedule my_daily -policy MirrorAllSnapshots
```

6. Resync the source and destination volumes:

```
snapmirror resync -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster. Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

The following example resyncs the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm1:volA -destination-path svm_backup:volA_dst
```

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

= Convert the type of a SnapMirror relationship
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

Beginning with ONTAP 9.5, SnapMirror Synchronous is supported. You can convert an asynchronous SnapMirror relationship to a SnapMirror Synchronous relationship or vice versa without performing a baseline transfer.

About this task

You cannot convert an asynchronous SnapMirror relationship to a SnapMirror Synchronous relationship or vice versa by changing the SnapMirror policy

Steps

- **Converting an asynchronous SnapMirror relationship to a SnapMirror Synchronous relationship**

- a. From the destination cluster, delete the asynchronous SnapMirror relationship:

```
snapmirror delete -destination-path SVM:volume
```

```
cluster2::>snapmirror delete -destination-path vs1_dr:vol1
```

- b. From the source cluster, release the SnapMirror relationship without deleting the common Snapshot copies:

```
snapmirror release -relationship-info-only true -destination-path dest_SVM:dest_volume
```

```
cluster1::>snapmirror release -relationship-info-only true -destination-path vs1_dr:vol1
```

- c. From the destination cluster, create a SnapMirror Synchronous relationship:

```
snapmirror create -source-path src_SVM:src_volume -destination-path  
dest_SVM:dest_volume -policy sync-mirror
```

```
cluster2::>snapmirror create -source-path vs1:vol1 -destination  
-path vs1_dr:vol1 -policy sync
```

- d. Resynchronize the SnapMirror Synchronous relationship:

```
snapmirror resync -destination-path dest_SVM:dest_volume
```

```
cluster2::>snapmirror resync -destination-path vs1_dr:vol1
```

- **Converting a SnapMirror Synchronous relationship to an asynchronous SnapMirror relationship**

- a. From the destination cluster, quiesce the existing SnapMirror Synchronous relationship:

```
snapmirror quiesce -destination-path dest_SVM:dest_volume
```

```
cluster2::> snapmirror quiesce -destination-path vs1_dr:vol1
```

- b. From the destination cluster, delete the asynchronous SnapMirror relationship:

```
snapmirror delete -destination-path SVM:volume
```

```
cluster2::>snapmirror delete -destination-path vs1_dr:vol1
```

- c. From the source cluster, release the SnapMirror relationship without deleting the common Snapshot copies:

```
snapmirror release -relationship-info-only true -destination-path  
dest_SVM:dest_volume
```

```
cluster1::>snapmirror release -relationship-info-only true  
-destination-path vs1_dr:vol1
```

- d. From the destination cluster, create an asynchronous SnapMirror relationship:

```
snapmirror create -source-path src_SVM:src_volume -destination-path  
dest_SVM:dest_volume -policy MirrorAllSnapshots
```

```
cluster2::>snapmirror create -source-path vs1:vol1 -destination-path vs1_dr:vol1 -policy sync
```

- e. Resynchronize the SnapMirror Synchronous relationship:

```
snapmirror resync -destination-path dest_SVM:dest_volume
```

```
cluster2::>snapmirror resync -destination-path vs1_dr:vol1
```

= Convert the mode of a SnapMirror Synchronous relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

Beginning with ONTAP 9.5, SnapMirror Synchronous relationships are supported. You can convert the mode of a SnapMirror Synchronous relationship from StrictSync to Sync or vice versa.

About this task

You cannot modify the policy of a Snapmirror Synchronous relationship to convert its mode.

Steps

1. From the destination cluster, quiesce the existing SnapMirror Synchronous relationship:

```
snapmirror quiesce -destination-path dest_SVM:dest_volume
```

```
cluster2::> snapmirror quiesce -destination-path vs1_dr:vol1
```

2. From the destination cluster, delete the existing SnapMirror Synchronous relationship:

```
snapmirror delete -destination-path dest_SVM:dest_volume
```

```
cluster2::> snapmirror delete -destination-path vs1_dr:vol1
```

3. From the source cluster, release the SnapMirror relationship without deleting the common Snapshot copies:

```
snapmirror release -relationship-info-only true -destination-path dest_SVM:dest_volume
```

```
cluster1::> snapmirror release -relationship-info-only true -destination-path vs1_dr:vol1
```

4. From the destination cluster, create a SnapMirror Synchronous relationship by specifying the mode to which you want to convert the SnapMirror Synchronous relationship:

```
snapmirror create -source-path vs1:vol1 -destination-path  
dest_SVM:dest_volume -policy Sync|StrictSync
```

```
cluster2::> snapmirror create -source-path vs1:vol1 -destination  
-path vs1_dr:vol1 -policy Sync
```

5. From the destination cluster, resynchronize the SnapMirror relationship:

```
snapmirror resync -destination-path dest_SVM:dest_volume
```

```
cluster2::> snapmirror resync -destination-path vs1_dr:vol1
```

= Serve data from a SnapMirror DR destination volume

= Make the destination volume writeable

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You need to make the destination volume writeable before you can serve data from the volume to clients. You can use the `snapmirror quiesce` command to stop scheduled transfers to the destination, the `snapmirror abort` command to stop ongoing transfers, and the `snapmirror break` command to make the destination writeable.

About this task

You must perform this task from the destination SVM or the destination cluster.

Steps

1. Stop scheduled transfers to the destination:

```
snapmirror quiesce -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

The following example stops scheduled transfers between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror quiesce -source-path svm1:volA  
-destination-path svm_backup:volA_dst
```

2. Stop ongoing transfers to the destination:

```
snapmirror abort -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

This step is not required for SnapMirror Synchronous relationships (supported beginning with ONTAP 9.5).

The following example stops ongoing transfers between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror abort -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

3. Break the SnapMirror DR relationship:

```
snapmirror break -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

The following example breaks the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror break -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
The redesigned System Manager (available with ONTAP 9.7 and later)	Serve data from a SnapMirror destination
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume disaster recovery overview

= Configure the destination volume for data access

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

After making the destination volume writeable, you must configure the volume for data access. NAS clients, NVMe subsystem, and SAN hosts can access the data from the destination volume until the source volume is reactivated.

NAS environment:

1. Mount the NAS volume to the namespace using the same junction path that the source volume was mounted to in the source SVM.
2. Apply the appropriate ACLs to the SMB shares at the destination volume.
3. Assign the NFS export policies to the destination volume.
4. Apply the quota rules to the destination volume.
5. Redirect clients to the destination volume.
6. Remount the NFS and SMB shares on the clients.

SAN environment:

1. Map the LUNs in the volume to the appropriate initiator group.
2. For iSCSI, create iSCSI sessions from the SAN host initiators to the SAN LIFs.
3. On the SAN client, perform a storage re-scan to detect the connected LUNs.

For information about NVMe environment, see [SAN administration](#).

= Reactivate the original source volume

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can reestablish the original data protection relationship between the source and destination volumes when you no longer need to serve data from the destination.

About this task

- The procedure below assumes that the baseline in the original source volume is intact. If the baseline is not intact, you must create and initialize the relationship between the volume you are serving data from and the original source volume before performing the procedure.
- Background preparation and the data warehousing phase of an XDP SnapMirror relationship can take a long time. It is not uncommon to see the SnapMirror relationship reporting the status "preparing" for an extended time period.

Steps

1. Delete the original data protection relationship:

```
snapmirror delete -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

The following example deletes the relationship between the original source volume, `volA` on `svm1`, and the volume you are serving data from, `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror delete -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

2. Reverse the original data protection relationship:

```
snapmirror resync -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster. Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

The following example reverses the relationship between the original source volume, `volA` on `svm1`, and the volume you are serving data from, `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm_backup:volA_dst
-destination-path svm1:volA
```

3. Stop the source SVM for the reversed relationship:

```
vserver stop -vserver SVM
```

For complete command syntax, see the man page.

The following example stops the source SVM for the reversed relationship:

```
cluster_src::> vserver stop svm_backup
```

4. Update the reversed relationship:

```
snapmirror update -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster. The command fails if a common Snapshot copy does not exist on the source and destination. Use `snapmirror initialize` to re-initialize the relationship.

The following example updates the relationship between the volume you are serving data from, `volA_dst` on `svm_backup`, and the original source volume, `volA` on `svm1`:

```
cluster_dst::> snapmirror update -source-path svm_backup:volA_dst
-destination-path svm1:volA
```

5. Stop scheduled transfers for the reversed relationship:

```
snapmirror quiesce -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

The following example stops scheduled transfers between the volume you are serving data from, `volA_dst` on `svm_backup`, and the original source volume, `volA` on `svm1`:

```
cluster_dst::> snapmirror quiesce -source-path svm_backup:volA_dst  
-destination-path svm1:volA
```

6. Stop ongoing transfers for the reversed relationship:

```
snapmirror abort -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

The following example stops ongoing transfers between the volume you are serving data from, `volA_dst` on `svm_backup`, and the original source volume, `volA` on `svm1`:

```
cluster_dst::> snapmirror abort -source-path svm_backup:volA_dst  
-destination-path svm1:volA
```

7. Break the reversed relationship:

```
snapmirror break -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

The following example breaks the relationship between the volume you are serving data from, `volA_dst` on `svm_backup`, and the original source volume, `volA` on `svm1`:

```
cluster_dst::> snapmirror break -source-path svm_backup:volA_dst  
-destination-path svm1:volA
```

8. Start the original source SVM:

```
vserver start -vserver SVM
```

For complete command syntax, see the man page.

The following example starts the original source SVM:

```
cluster_dst::> vserver start svm1
```

9. Delete the reversed data protection relationship:

```
snapmirror delete -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the source SVM or the source cluster for the reversed relationship.

The following example deletes the reversed relationship between the original source volume, `volA` on `svm1`, and the volume you are serving data from, `volA_dst` on `svm_backup`:

```
cluster_src::> snapmirror delete -source-path svm_backup:volA_dst
-destination-path svm1:volA
```

10. Reestablish the original data protection relationship:

```
snapmirror resync -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

The following example reestablishes the relationship between the original source volume, `volA` on `svm1`, and the original destination volume, `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm1:volA -destination
-path svm_backup:volA_dst
```

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

= Restore files from a SnapMirror destination volume

= Restore a single file, LUN, or NVMe namespace from a SnapMirror destination

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can restore a single file, LUN, a set of files or LUNs from a Snapshot copy, or an NVMe namespace from a SnapMirror destination volume. Beginning with ONTAP 9.7, you can also restore NVMe namespaces from a SnapMirror Synchronous destination. You can restore files to the original source volume or to a different volume.

What you'll need

To restore a file or LUN from a SnapMirror Synchronous destination (supported beginning with ONTAP 9.5), you must first delete and release the relationship.

About this task

The volume to which you are restoring files or LUNs (the destination volume) must be a read-write volume:

- SnapMirror performs an *incremental restore* if the source and destination volumes have a common Snapshot copy (as is typically the case when you are restoring to the original source volume).
 - Otherwise, SnapMirror performs a *baseline restore*, in which the specified Snapshot copy and all the data blocks it references are transferred to the destination volume.

Steps

1. List the Snapshot copies in the destination volume:

```
volume snapshot show -vserver SVM -volume volume
```

For complete command syntax, see the man page.

The following example shows the Snapshot copies on the vserverB:secondary1 destination:

```
cluster_dst:> volume snapshot show -vserver vserverB -volume  
secondary1
```

Vserver	Volume	Snapshot	State	Size
Total%	Used%			
-----	-----	-----	-----	-----
vserverB	secondary1	hourly.2013-01-25_0005	valid	224KB 0%
0%		daily.2013-01-25_0010	valid	92KB 0%
0%		hourly.2013-01-25_0105	valid	228KB 0%
0%		hourly.2013-01-25_0205	valid	236KB 0%
0%		hourly.2013-01-25_0305	valid	244KB 0%
0%		hourly.2013-01-25_0405	valid	244KB 0%
0%		hourly.2013-01-25_0505	valid	244KB 0%

7 entries were displayed.

2. Restore a single file or LUN or a set of files or LUNs from a Snapshot copy in a SnapMirror destination volume:

```
snapmirror restore -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ... -source-snapshot
snapshot -file-list source_file_path,@destination_file_path
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

The following command restores the files `file1` and `file2` from the Snapshot copy `daily.2013-01-25_0010` in the original destination volume `secondary1`, to the same location in the active file system of the original source volume `primary1`:

```
cluster_dst::> snapmirror restore -source-path vserverB:secondary1
-destination-path vserverA:primary1 -source-snapshot daily.2013-01-
25_0010 -file-list /dir1/file1,/dir2/file2
```

```
[Job 3479] Job is queued: snapmirror restore for the relationship
with destination vserverA:primary1
```

The following command restores the files `file1` and `file2` from the Snapshot copy `daily.2013-01-25_0010` in the original destination volume `secondary1`, to a different location in the active file system of the original source volume `primary1`.

The destination file path begins with the `@` symbol followed by the path of the file from the root of the original source volume. In this example, `file1` is restored to `/dir1/file1.new` and `file2` is restored to `/dir2.new/file2` on `primary1`:

```
cluster_dst::> snapmirror restore -source-path vserverB:secondary1
-destination-path vserverA:primary1 -source-snapshot daily.2013-01-
25_0010 -file-list
/di/file1,@/dir1/file1.new,/dir2/file2,@/dir2.new/file2
```

```
[Job 3479] Job is queued: snapmirror restore for the relationship
with destination vserverA:primary1
```

The following command restores the files `file1` and `file3` from the Snapshot copy `daily.2013-01-25_0010` in the original destination volume `secondary1`, to different locations in the active file system of the original source volume `primary1`, and restores `file2` from `snap1` to the same location in the active file system of `primary1`.

In this example, the file `file1` is restored to `/dir1/file1.new` and `file3` is restored to `/dir3.new/file3`:

```
cluster_dst::> snapmirror restore -source-path vserverB:secondary1  
-destination-path vserverA:primary1 -source-snapshot daily.2013-01-  
25_0010 -file-list  
/dir/file1,@/dir1/file1.new,/dir2/file2,/dir3/file3,@/dir3.new/file3  
  
[Job 3479] Job is queued: snapmirror restore for the relationship  
with destination vserverA:primary1
```

= Restore the contents of a volume from a SnapMirror destination

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can restore the contents of an entire volume from a Snapshot copy in a SnapMirror destination volume. You can restore the volume's contents to the original source volume or to a different volume.

About this task

The destination volume for the restore operation must be one of the following:

- A read-write volume, in which case SnapMirror performs an *incremental restore*, provided that the source and destination volumes have a common Snapshot copy (as is typically the case when you are restoring to the original source volume).

The command fails if there is not a common Snapshot copy. You cannot restore the contents of a volume to an empty read-write volume.

- An empty data protection volume, in which case SnapMirror performs a *baseline restore*, in which the specified Snapshot copy and all the data blocks it references are transferred to the source volume.

Restoring the contents of a volume is a disruptive operation. SMB traffic must not be running on the SnapVault primary volume when a restore operation is running.

If the destination volume for the restore operation has compression enabled, and the source volume does not have compression enabled, disable compression on the destination volume. You need to re-enable compression after the restore operation is complete.

Any quota rules defined for the destination volume are deactivated before the restore is performed. You can use the `volume quota modify` command to reactivate quota rules after the restore operation is complete.

Steps

1. List the Snapshot copies in the destination volume:

```
volume snapshot show -vserver SVM -volume volume
```

For complete command syntax, see the man page.

The following example shows the Snapshot copies on the vserverB:secondary1 destination:

```

cluster_dst::> volume snapshot show -vserver vserverB -volume
secondary1

      Vserver      Volume      Snapshot          State     Size
      Total% Used%
      -----  -----
      -----  -----
vserverB      secondary1  hourly.2013-01-25_0005  valid    224KB   0%
0%           0%
              daily.2013-01-25_0010   valid    92KB    0%
0%           0%
              hourly.2013-01-25_0105  valid    228KB   0%
0%           0%
              hourly.2013-01-25_0205  valid    236KB   0%
0%           0%
              hourly.2013-01-25_0305  valid    244KB   0%
0%           0%
              hourly.2013-01-25_0405  valid    244KB   0%
0%           0%
              hourly.2013-01-25_0505  valid    244KB   0%
0%           0%

7 entries were displayed.

```

2. Restore the contents of a volume from a Snapshot copy in a SnapMirror destination volume:

```

snapmirror restore -source-path SVM:volume|cluster://SVM/volume, ...
-destination-path SVM:volume|cluster://SVM/volume, ... -source-snapshot
snapshot

```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

The following command restores the contents of the original source volume `primary1` from the Snapshot copy `daily.2013-01-25_0010` in the original destination volume `secondary1`:

```
cluster_dst::> snapmirror restore -source-path vserverB:secondary1  
-destination-path vserverA:primary1 -source-snapshot daily.2013-01-  
25_0010
```

Warning: All data newer than Snapshot copy daily.2013-01-25_0010 on volume vserverA:primary1 will be deleted.

Do you want to continue? {y|n}: y

```
[Job 34] Job is queued: snapmirror restore from source  
vserverB:secondary1 for the snapshot daily.2013-01-25_0010.
```

3. Remount the restored volume and restart all applications that use the volume.

== Other ways to do this in ONTAP

To perform these tasks with...	See this content...
The redesigned System Manager (available with ONTAP 9.7 and later)	Restore a volume from an earlier Snapshot copy
System Manager Classic (available with ONTAP 9.7 and earlier)	Volume restore using SnapVault overview

= Update a replication relationship manually

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You might need to update a replication relationship manually if an update fails because the source volume has been moved.

About this task

SnapMirror aborts any transfers from a moved source volume until you update the replication relationship manually.

Beginning with ONTAP 9.5, SnapMirror Synchronous relationships are supported. Although the source and destination volumes are in sync at all times in these relationships, the view from the secondary cluster is synchronized with the primary only on an hourly basis. If you want to view the point-in-time data at the destination, you should perform a manual update by running the `snapmirror update` command.

Step

1. Update a replication relationship manually:

```
snapmirror update -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster. The command fails if a common Snapshot copy does not exist on the source and destination. Use `snapmirror initialize` to re-initialize the relationship.

The following example updates the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_src::> snapmirror update -source-path svm1:volA -destination -path svm_backup:volA_dst
```

= Resynchronize a replication relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

You need to resynchronize a replication relationship after you make a destination volume writeable, after an update fails because a common Snapshot copy does not exist on the source and destination volumes, or if you want to change the replication policy for the relationship.

About this task

- Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.
- Volumes that are part of a fan-out or cascade configuration can take longer to resynchronize. It is not uncommon to see the SnapMirror relationship reporting the status "preparing" for an extended time period.

Step

1. Resync the source and destination volumes:

```
snapmirror resync -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ... -type DP|XDP -schedule  
schedule -policy policy
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster.

The following example resyncs the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm1:volA -destination -path svm_backup:volA_dst
```

= Delete a volume replication relationship

:icons: font

```
:relative_path: ./data-protection/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/
```

You can use the `snapmirror delete` and `snapmirror release` commands to delete a volume replication relationship. You can then delete unneeded destination volumes manually.

About this task

The `snapmirror release` command deletes any SnapMirror-created Snapshot copies from the source. You can use the `-relationship-info-only` option to preserve the Snapshot copies.

Steps

1. Quiesce the replication relationship:

```
snapmirror quiesce -destination-path SVM:volume|cluster://SVM/volume  
  
cluster_dst::> snapmirror quiesce -destination-path  
svm_backup:volA_dst
```

2. Delete the replication relationship:

```
snapmirror delete -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the destination cluster or destination SVM.

The following example deletes the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror delete -source-path svm1:volA -destination  
-path svm_backup:volA_dst
```

3. Release replication relationship information from the source SVM:

```
snapmirror release -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ...
```

For complete command syntax, see the man page.

You must run this command from the source cluster or source SVM.

The following example releases information for the specified replication relationship from the source SVM `svm1`:

```
cluster_src::> snapmirror release -source-path svml:volA  
-destination-path svm_backup:volA_dst
```

= Manage storage efficiency

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

SnapMirror preserves storage efficiency on the source and destination volumes, with one exception, when postprocess data compression is enabled on the destination. In that case, all storage efficiency is lost on the destination. To correct this issue, you need to disable postprocess compression on the destination, update the relationship manually, and re-enable storage efficiency.

What you'll need

- The source and destination clusters and SVMs must be peered.

[Cluster and SVM peering](#)

- You must disable postprocess compression on the destination.

About this task

You can use the `volume efficiency show` command to determine whether efficiency is enabled on a volume. For more information, see the man pages.

You can check if SnapMirror is maintaining storage efficiency by viewing the SnapMirror audit logs and locating the transfer description. If the transfer description displays `transfer_desc=Logical Transfer`, SnapMirror is not maintaining storage efficiency. If the transfer description displays `transfer_desc=Logical Transfer with Storage Efficiency`, SnapMirror is maintaining storage efficiency. For example:

```
Fri May 22 02:13:02 CDT 2020 ScheduledUpdate[May 22 02:12:00]:cc0fbc29-  
b665-11e5-a626-00a09860c273 Operation-Uuid=39fbef48-550a-4282-a906-  
df35632c73a1 Group=none Operation-Cookie=0 action=End  
source=<sourcepath> destination=<destpath> status=Success  
bytes_transferred=117080571 network_compression_ratio=1.0:1  
transfer_desc=Logical Transfer - Optimized Directory Mode
```

Logical Transfer with storage

Beginning with ONTAP 9.3, manual update is no longer required to re-enable storage efficiency. If SnapMirror detects that postprocess compression has been disabled, it automatically re-enables storage efficiency at the next scheduled update. Both the source and the destination must be running ONTAP 9.3.

Beginning with ONTAP 9.3, AFF systems manage storage efficiency settings differently from FAS systems after a destination volume is made writeable:

- After you make a destination volume writeable using the `snapmirror break` command, the caching

policy on the volume is automatically set to “auto” (the default).

This behavior is applicable to FlexVol volumes, only, and it does not apply to FlexGroup volumes.

- On resync, the caching policy is automatically set to “none”, and deduplication and inline compression are automatically disabled, regardless of your original settings. You must modify the settings manually as needed.

Manual updates with storage efficiency enabled can be time-consuming. You might want to run the operation in off-peak hours.

Step

- Update a replication relationship and re-enable storage efficiency:

```
snapmirror update -source-path SVM:volume|cluster://SVM/volume, ...
-dstination-path SVM:volume|cluster://SVM/volume, ... -enable-storage
-efficiency true
```

For complete command syntax, see the man page.

You must run this command from the destination SVM or the destination cluster. The command fails if a common Snapshot copy does not exist on the source and destination. Use snapmirror initialize to re-initialize the relationship.

The following example updates the relationship between the source volume `volA` on `svm1` and the destination volume `volA_dst` on `svm_backup`, and re-enables storage efficiency:

```
cluster_dst::> snapmirror update -source-path svm1:volA -destination
-path svm_backup:volA_dst -enable-storage-efficiency true
```

= Use SnapMirror global throttling

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest//media/

Global network throttling is available for all SnapMirror and SnapVault transfers at a per-node level.

About this task

SnapMirror global throttling restricts the bandwidth used by incoming and/or outgoing SnapMirror and SnapVault transfers. The restriction is enforced cluster wide on all nodes in the cluster.

For example, if the outgoing throttle is set to 100 Mbps, each node in the cluster will have the outgoing bandwidth set to 100 Mbps. If global throttling is disabled, it is disabled on all nodes.

The throttle has no effect on `volume move` transfers or load-sharing mirror transfers. Although data transfer rates are often expressed in bits per second (bps), the throttle values must be entered in kilobytes per second (KBps).

Global throttling works with the per-relationship throttle feature for SnapMirror and SnapVault transfers. The per-relationship throttle is enforced until the combined bandwidth of per-relationship transfers exceeds the value of the global throttle, after which the global throttle is enforced. A throttle value 0 implies that global throttling is disabled.

 SnapMirror global throttling has no effect on SnapMirror Synchronous relationships when they are In-Sync. However, the throttle does effect SnapMirror Synchronous relationships when they perform an asynchronous transfer phase such as an initialization operation or after an Out Of Sync event. For this reason, enabling global throttling with SnapMirror Synchronous relationships is not recommended.

Steps

1. Enable global throttling:

```
options -option-name replication.throttle.enable on|off
```

The following example shows how to enable SnapMirror global throttling on `cluster_dst`:

```
cluster_dst::> options -option-name replication.throttle.enable on
```

2. Specify the maximum total bandwidth used by incoming transfers:

```
options -option-name replication.throttle.incoming.max_kbs KBps
```

The recommended minimum throttle bandwidth is 4 KBps and the maximum is up to 2 TBps. The default value for this option is `unlimited`, which means there is no limit on total bandwidth used.

The following example shows how to set the maximum total bandwidth used by incoming transfers to 100 Mbps:

```
cluster_dst::> options -option-name  
replication.throttle.incoming.max_kbs 12500
```

100 Mbps = 12500 KBps

3. Specify the maximum total bandwidth used by outgoing transfers:

```
options -option-name replication.throttle.outgoing.max_kbs KBps
```

KBps is the maximum transfer rate in kilobytes per second. Valid transfer rate values are 1 to 125000. The default value for this option is `unlimited`, which means there is no limit on total bandwidth used.

The following example shows how to set the maximum total bandwidth used by outgoing transfers to 100 Mbps:

```
cluster_dst::> options -option-name  
replication.throttle.outgoing.max_kbs 12500
```

= About SnapMirror SVM replication

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use SnapMirror to create a data protection relationship between SVM. In this type of data protection relationship, all or part of the SVM's configuration, from NFS exports and SMB shares to RBAC, is replicated, as well as the data in the volumes that the SVM owns.

== Supported relationship types

Only data-serving SVM can be replicated. The following data protection relationship types are supported:

- *SnapMirror DR*, in which the destination typically contains only the Snapshot copies currently on the source.

Beginning with ONTAP 9.9.1, this behavior changes when you are using the mirror-vault policy.

Beginning with ONTAP 9.9.1, you can create different Snapshot policies on the source and destination, and the Snapshot copies on the destination are not overwritten by Snapshot copies on the source:

- They are not overwritten from the source to the destination during normal scheduled operations, updates and resync
- They are not deleted during break operations.

- They are not deleted during flip-resync operations.

When you configure an SVM DR relationship using the mirror-vault policy using ONTAP 9.9.1 and later, the policy behaves as follows:

- User-defined Snapshot copy policies at the source are not copied to the destination.
- System-defined Snapshot copy policies are not copied to the destination.
- Volume association with user and system defined Snapshot policies are not copied to the destination.

SVM.

- Beginning with ONTAP 9.2, *SnapMirror unified replication*, in which the destination is configured for both DR and long-term retention.

Details about these relationship types can be found here: [Understanding SnapMirror volume replication](#).

The *policy type* of the replication policy determines the type of relationship it supports. The following table shows the available policy types.

Policy type	Relationship type
async-mirror	SnapMirror DR

== XDP replaces DP as the SVM replication default in ONTAP 9.4

Beginning with ONTAP 9.4, SVM data protection relationships default to XDP mode. SVM data protection relationships continue to default to DP mode in ONTAP 9.3 and earlier.

Existing relationships are not affected by the new default. If a relationship is already of type DP, it will continue to be of type DP. The following table shows the behavior you can expect.

If you specify...	The type is...	The default policy (if you do not specify a policy) is...
DP	XDP	MirrorAllSnapshots (SnapMirror DR)
Nothing	XDP	MirrorAllSnapshots (SnapMirror DR)
XDP	XDP	MirrorAndVault (Unified replication)

Details about the changes in the default can be found here: [XDP replaces DP as the SnapMirror default](#).

Version-independence is not supported for SVM replication.

Compatible ONTAP versions for SnapMirror relationships

== How SVM configurations are replicated

The content of an SVM replication relationship is determined by the interaction of the following fields:

- The `-identity-preserve true` option of the `snapmirror create` command replicates the entire SVM configuration.
The `-identity-preserve false` option replicates only the volumes and authentication and authorization configurations of the SVM, and the protocol and name service settings listed in [Configurations replicated in SVM DR relationships](#).
- The `-discard-configs network` option of the `snapmirror policy create` command excludes LIFs and related network settings from SVM replication, for use in cases where the source and destination SVMs are in different subnets.
- The `-vserver-dr-protection unprotected` option of the `volume modify` command excludes the specified volume from SVM replication.

Otherwise, SVM replication is almost identical to volume replication. You can use virtually the same workflow for SVM replication as you use for volume replication.

== Support details

The following table shows support details for SnapMirror SVM replication.

Resource or feature	Support details
Relationship types	<ul style="list-style-type: none"> • SnapMirror DR • Beginning with ONTAP 9.2, SnapMirror unified replication
Replication scope	Intercluster only. You cannot replicate SVMs in the same cluster.
Version-independence	Not supported.
Deployment types	<ul style="list-style-type: none"> • Single source to single destination • Beginning with ONTAP 9.4, fan-out. You can fan-out to two destinations only. <p>By default, only one -identity-preserve true relationship is allowed per source SVM.</p>
Volume encryption	<ul style="list-style-type: none"> • Encrypted volumes on the source are encrypted on the destination. • Onboard Key Manager or KMIP servers must be configured on the destination. • New encryption keys are generated at the destination. • If the destination does not contain a node that supports volume .encryption, replication succeeds, but the destination volumes are not encrypted.
FabricPool	Beginning with ONTAP 9.6, SnapMirror SVM replication is supported with FabricPools.

MetroCluster	<p>Beginning with ONTAP 9.5, SnapMirror SVM replication is supported on MetroCluster configurations.</p> <ul style="list-style-type: none"> • A MetroCluster configuration cannot be the destination of an SVM DR relationship. • Only an active SVM within a MetroCluster configuration can be the source of an SVM DR relationship. <p>A source can be a sync-source SVM before switchover or a sync-destination SVM after switchover.</p> <ul style="list-style-type: none"> • When a MetroCluster configuration is in a steady state, the MetroCluster sync-destination SVM cannot be the source of an SVM DR relationship, since the volumes are not online. • When the sync-source SVM is the source of an SVM DR relationship, the source SVM DR relationship information is replicated to the MetroCluster partner. • During the switchover and switchback processes, replication to the SVM DR destination might fail. <p>However, after the switchover or switchback process completes, the next SVM DR scheduled updates will succeed.</p>
SnapMirror Synchronous	Not supported with SVM DR.

== Configurations replicated in SVM DR relationships

= Manage SnapMirror SVM replication

= Replicate SVM configurations

= SnapMirror SVM replication workflow

:icons: font

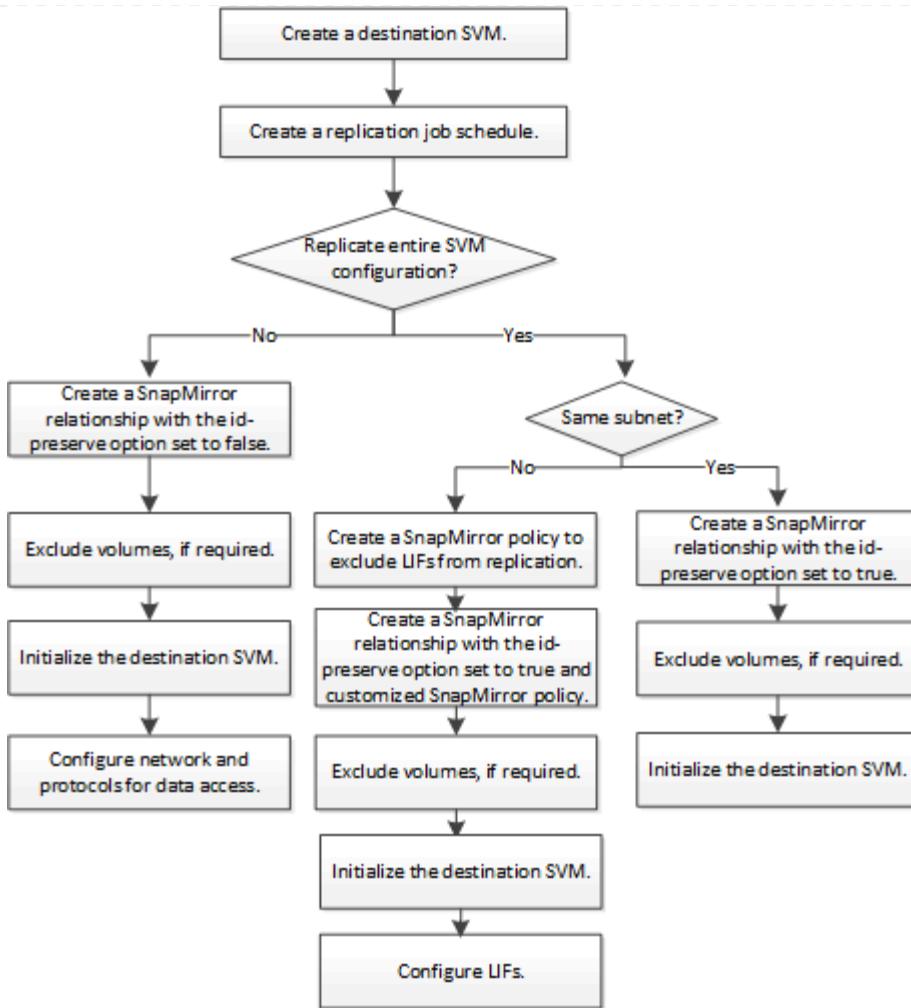

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

SnapMirror SVM replication involves creating the destination SVM, creating a replication job schedule, and creating and initializing a SnapMirror relationship.

This workflow assumes that you are already using a default policy or a custom replication policy.

= Criteria for placing volumes on destination SVMs

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

When replicating volumes from the source SVM to the destination SVM, it's important to know the criteria for selecting aggregates.

Aggregates are selected based on the following criteria:

- Volumes are always placed on non-root aggregates.
- Non-root aggregates are selected based on the available free space and the number of volumes already hosted on the aggregate.

Aggregates with more free space and fewer volumes are given priority. The aggregate with the highest priority is selected.

- Source volumes on FabricPool aggregates are placed on FabricPool aggregates on the destination with the same tiering-policy.
- If a volume on the source SVM is located on a Flash Pool aggregate, then the volume is placed on a Flash Pool aggregate on the destination SVM, if such an aggregate exists and has enough free space.

- If the `-space-guarantee` option of the volume that is replicated is set to `volume`, only aggregates with free space greater than the volume size are considered.
- The volume size grows automatically on the destination SVM during replication, based on the source volume size.

If you want to pre-reserve the size on the destination SVM, you must resize the volume. The volume size does not shrink automatically on the destination SVM based on the source SVM.

If you want to move a volume from one aggregate to another, you can use the `volume move` command on the destination SVM.

= Replicate an entire SVM configuration
 :icons: font
 :relative_path: ./data-protection/
 :imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use the `-identity-preserve true` option of the `snapmirror create` command to replicate an entire SVM configuration.

What you'll need

The source and destination clusters and SVMs must be peered.

For complete command syntax, see the man page.

About this task

This workflow assumes that you are already using a default policy or a custom replication policy.

Beginning with ONTAP 9.9.1, when you use the mirror-vault policy, you can create different Snapshot policies on the source and destination SVM, and the Snapshot copies on the destination are not overwritten by Snapshot copies on the source. For more information, see [Understanding SnapMirror SVM replication](#).

Steps

1. Create a destination SVM:

```
vserver create -vserver SVM_name -subtype dp-destination
```

The SVM name must be unique across the source and destination clusters.

The following example creates a destination SVM named `svm_backup`:

```
cluster_dst:> vserver create -vserver svm_backup -subtype dp-destination
```

2. Create a replication job schedule:

```
job schedule cron create -name job_name -month month -dayofweek day_of_week
-day day_of_month -hour hour -minute minute
```

For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the

week, and hour, respectively.

The following example creates a job schedule named `my_weekly` that runs on Saturdays at 3:00 a.m.:

```
cluster_dst::> job schedule cron create -name my_weekly -dayofweek saturday -hour 3 -minute 0
```

3. From the destination SVM or the destination cluster, create a replication relationship:

```
snapmirror create -source-path SVM_name: -destination-path SVM_name: -type DP|XDP -schedule schedule -policy policy -identity-preserve true
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options.

The following example creates a SnapMirror DR relationship using the default `MirrorAllSnapshots` policy:

```
cluster_dst::> snapmirror create -source-path svm1: -destination-path svm_backup: -type XDP -schedule my_daily -policy MirrorAllSnapshots -identity-preserve true
```

The following example creates a unified replication relationship using the default `MirrorAndVault` policy:

```
cluster_dst::> snapmirror create -source-path svm1: -destination-path svm_backup: -type XDP -schedule my_daily -policy MirrorAndVault -identity-preserve true
```

Assuming you have created a custom policy with the policy type `async-mirror`, the following example creates a SnapMirror DR relationship:

```
cluster_dst::> snapmirror create -source-path svm1: -destination-path svm_backup: -type XDP -schedule my_daily -policy my_mirrored -identity-preserve true
```

Assuming you have created a custom policy with the policy type `mirror-vault`, the following example creates a unified replication relationship:

```
cluster_dst::> snapmirror create -source-path svm1: -destination-path svm_backup: -type XDP -schedule my_daily -policy my_unified -identity-preserve true
```

4. Stop the destination SVM:

```
vserver stop
```

SVM name

The following example stops a destination SVM named dvs1:

```
cluster_dst::> vserver stop -vserver dvs1
```

5. From the destination SVM or the destination cluster, initialize the SVM replication relationship: +

```
snapmirror initialize -source-path SVM_name: -destination-path SVM_name:
```

The following example initializes the relationship between the source SVM, svm1, and the destination SVM, svm_backup:

```
cluster_dst::> snapmirror initialize -source-path svm1: -destination -path svm_backup:
```

= Exclude LIFs and related network settings from SVM replication

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

If the source and destination SVMs are in different subnets, you can use the **-discard-configs** network option of the **snapmirror policy create** command to exclude LIFs and related network settings from SVM replication.

What you'll need

The source and destination clusters and SVMs must be peered.

About this task

The **-identity-preserve** option of the **snapmirror create** command must be set to **true** when you create the SVM replication relationship.

For complete command syntax, see the man page.

Steps

1. Create a destination SVM:

```
vserver create -vserver SVM -subtype dp-destination
```

The SVM name must be unique across the source and destination clusters.

The following example creates a destination SVM named *svm_backup*:

```
cluster_dst:> vserver create -vserver svm_backup -subtype dp-destination
```

2. Create a job schedule:

```
job schedule cron create -name job_name -month month -dayofweek day_of_week -day day_of_month -hour hour -minute minute
```

For *-month*, *-dayofweek*, and *-hour*, you can specify `all` to run the job every month, day of the week, and hour, respectively.

The following example creates a job schedule named `my_weekly` that runs on Saturdays at 3:00 a.m.:

```
cluster_dst::> job schedule cron create -name my_weekly -dayofweek "Saturday" -hour 3 -minute 0
```

3. Create a custom replication policy:

```
snapmirror policy create -vserver SVM -policy policy -type async-mirror|vault|mirror-vault -comment comment -tries transfer_tries -transfer-priority low|normal -is-network-compression-enabled true|false -discard -configs network
```

For complete command syntax, see the man page.

The following example creates a custom replication policy for SnapMirror DR that excludes LIFs:

```
cluster_dst::> snapmirror policy create -vserver svm1 -policy DR_exclude_LIFs -type async-mirror -discard-configs network
```

The following example creates a custom replication policy for unified replication that excludes LIFs:

```
cluster_dst::> snapmirror policy create -vserver svm1 -policy unified_exclude_LIFs -type mirror-vault -discard-configs network
```

4. From the destination SVM or the destination cluster, run the following command to create a replication relationship:

```
snapmirror create -source-path SVM: -destination-path SVM: -type DP|XDP -schedule schedule -policy policy -identity-preserve true|false
```

You must enter a colon (:) after the SVM name in the *-source-path* and *-destination-path* options. See the examples below.

The following example creates a SnapMirror DR relationship that excludes LIFs:

```
cluster_dst::> snapmirror create -source-path svm1: -destination  
-path svm_backup: -type XDP -schedule my_daily -policy  
DR_exclude_LIFs -identity-preserve true
```

The following example creates a SnapMirror unified replication relationship that excludes LIFs:

```
cluster_dst::> snapmirror create -source-path svm1: -destination  
-path svm_backup: -type XDP -schedule my_daily -policy  
unified_exclude_LIFs -identity-preserve true
```

5. Stop the destination SVM:

```
vserver stop
```

SVM name

The following example stops a destination SVM named dvs1:

```
cluster_dst::> vserver stop -vserver dvs1
```

6. From the destination SVM or the destination cluster, initialize a replication relationship:

```
snapmirror initialize -source-path SVM: -destination-path SVM:
```

For complete command syntax, see the man page.

The following example initializes the relationship between the source, *svm1* and the destination, *svm_backup*:

```
cluster_dst::> snapmirror initialize -source-path svm1: -destination  
-path svm_backup:
```

After you finish

You must configure the network and protocols on the destination SVM for data access in the event a disaster occurs.

= Exclude network, name service, and other settings from SVM replication
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use the *-identity-preserve false* option of the *snapmirror create* command to replicate only the volumes and security configurations of an SVM. Some protocol and name service settings are also preserved.

What you'll need

The source and destination clusters and SVMs must be peered.

About this task

For a list of preserved protocol and name service settings, see [Configurations replicated in SVM DR relationships](#).

For complete command syntax, see the man page.

Steps

1. Create a destination SVM:

```
vserver create -vserver SVM -subtype dp-destination
```

The SVM name must be unique across the source and destination clusters.

The following example creates a destination SVM named `svm_backup`:

```
cluster_dst:> vserver create -vserver svm_backup -subtype dp-destination
```

2. Create a replication job schedule:

```
job schedule cron create -name job_name -month month -dayofweek day_of_week  
-day day_of_month -hour hour -minute minute
```

For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the week, and hour, respectively.

The following example creates a job schedule named `my_weekly` that runs on Saturdays at 3:00 a.m.:

```
cluster_dst:> job schedule cron create -name my_weekly -dayofweek  
"Saturday" -hour 3 -minute 0
```

3. Create a replication relationship that excludes network, name service, and other configuration settings:

```
snapmirror create -source-path SVM: -destination-path SVM: -type DP|XDP  
-schedule schedule -policy policy -identity-preserve false
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the examples below. You must run this command from the destination SVM or the destination cluster.

The following example creates a SnapMirror DR relationship using the default `MirrorAllSnapshots` policy. The relationship excludes network, name service, and other configuration settings from SVM replication:

```
cluster_dst::> snapmirror create -source-path svm1: -destination-path svm_backup: -type XDP -schedule my_daily -policy MirrorAllSnapshots -identity-preserve false
```

The following example creates a unified replication relationship using the default `MirrorAndVault` policy. The relationship excludes network, name service, and other configuration settings:

```
cluster_dst::> snapmirror create svm1: -destination-path svm_backup: -type XDP -schedule my_daily -policy MirrorAndVault -identity-preserve false
```

Assuming you have created a custom policy with the policy type `async-mirror`, the following example creates a SnapMirror DR relationship. The relationship excludes network, name service, and other configuration settings from SVM replication:

```
cluster_dst::> snapmirror create -source-path svm1: -destination-path svm_backup: -type XDP -schedule my_daily -policy my_mirrored -identity-preserve false
```

Assuming you have created a custom policy with the policy type `mirror-vault`, the following example creates a unified replication relationship. The relationship excludes network, name service, and other configuration settings from SVM replication:

```
cluster_dst::> snapmirror create -source-path svm1: -destination-path svm_backup: -type XDP -schedule my_daily -policy my_unified -identity-preserve false
```

4. Stop the destination SVM:

```
vserver stop
```

SVM name

The following example stops a destination SVM named `dvs1`:

```
destination_cluster::> vserver stop -vserver dvs1
```

5. If you are using SMB, you must also configure an SMB server.

See [SMB only: Creating an SMB server](#).

6. From the destination SVM or the destination cluster, initialize the SVM replication relationship:

```
snapmirror initialize -source-path SVM_name: -destination-path SVM_name:
```

After you finish

You must configure the network and protocols on the destination SVM for data access in the event a disaster occurs.

= Specify aggregates to use for SVM DR relationships

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

After a disaster recovery SVM is created, you can use the aggr-list option with vserver modify command to limit which aggregates are used to host SVM DR destination volumes.

Step

1. Create a destination SVM:

```
vserver create -vserver SVM -subtype dp-destination
```

2. Modify the disaster recovery SVM's aggr-list to limit the aggregates that are used to host the disaster recovery SVM's volume:

```
cluster_dest::> vserver modify -vserver SVM -aggr-list <comma-separated-list>
```

= SMB only: Create a SMB server

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

If the source SVM has an SMB configuration, and you chose to set identity-preserve to false, you must create a SMB server for the destination SVM. SMB server is required for some SMB configurations, such as shares during initialization of the SnapMirror relationship.

Steps

1. Start the destination SVM by using the vserver start command.

```
destination_cluster::> vserver start -vserver dvs1  
[Job 30] Job succeeded: DONE
```

2. Verify that the destination SVM is in the running state and subtype is dp-destination by using the vserver show command.

```

destination_cluster::> vserver show
                                         Admin      Operational Root
Vserver   Type    Subtype        State      State      Volume
Aggregate
-----
-----
dvs1     data    dp-destination  running   running   -
-
```

3. Create a LIF by using the `network interface create` command.

```

destination_cluster::>network interface create -vserver dvs1 -lif
NAS1 -role data -data-protocol cifs -home-node destination_cluster-
01 -home-port a0a-101 -address 192.0.2.128 -netmask 255.255.255.128
```

4. Create a route by using the `network route create` command.

```

destination_cluster::>network route create -vserver dvs1
-destination 0.0.0.0/0
-gateway 192.0.2.1
```

Network management

5. Configure DNS by using the `vserver services dns create` command.

```

destination_cluster::>vserver services dns create -domains
mydomain.example.com -vserver
dvs1 -name-servers 192.0.2.128 -state enabled
```

6. Add the preferred domain controller by using the `vserver cifs domain preferred-dc add` command.

```

destination_cluster::>vserver cifs domain preferred-dc add -vserver
dvs1 -preferred-dc
192.0.2.128 -domain mydomain.example.com
```

7. Create the SMB server by using the `vserver cifs create` command.

```
destination_cluster::>vserver cifs create -vserver dvs1 -domain mydomain.example.com -cifs-server CIFS1
```

8. Stop the destination SVM by using the vserver stop command.

```
destination_cluster::> vserver stop -vserver dvs1  
[Job 46] Job succeeded: DONE
```

= Exclude volumes from SVM replication
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

By default, all RW data volumes of the source SVM are replicated. If you do not want to protect all the volumes on the source SVM, you can use the **-vserver-dr-protection unprotected** option of the volume modify command to exclude volumes from SVM replication.

Steps

1. Exclude a volume from SVM replication:

```
volume modify -vserver SVM -volume volume -vserver-dr-protection  
unprotected
```

For complete command syntax, see the man page.

The following example excludes the volume `volA_src` from SVM replication:

```
cluster_src::> volume modify -vserver SVM1 -volume volA_src -vserver  
-dr-protection unprotected
```

If you later want to include a volume in the SVM replication that you originally excluded, run the following command:

```
volume modify -vserver SVM -volume volume -vserver-dr-protection protected
```

The following example includes the volume `volA_src` in the SVM replication:

```
cluster_src::> volume modify -vserver SVM1 -volume volA_src -vserver  
-dr-protection protected
```

2. Create and initialize the SVM replication relationship as described in [Replicating an entire SVM configuration](#),

= Serve data from an SVM DR destination

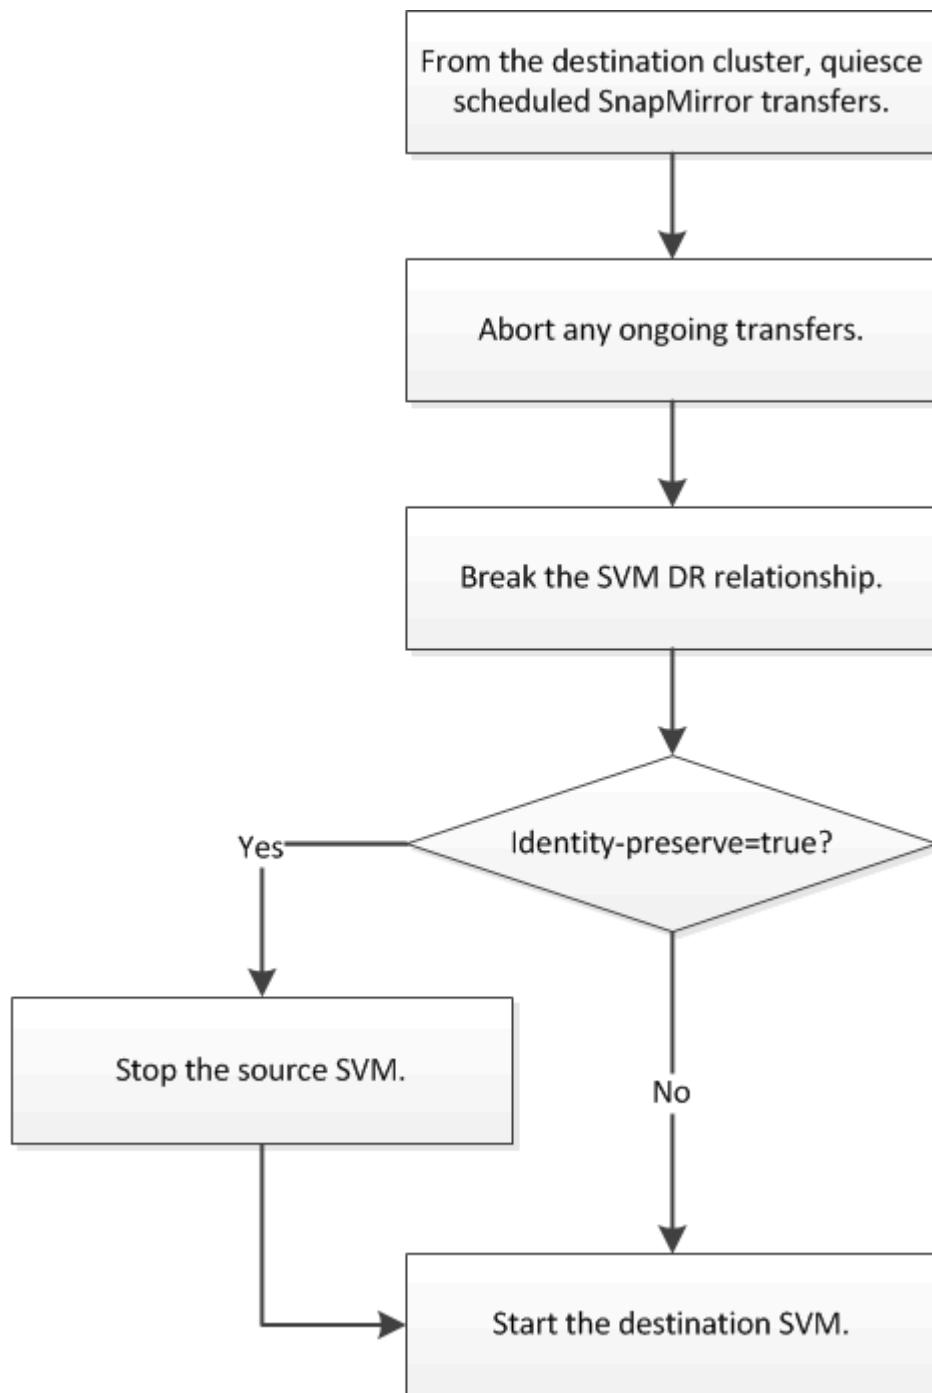

= SVM disaster recovery workflow

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

To recover from a disaster and serve data from the destination SVM, you must activate the destination SVM. Activating the destination SVM involves stopping scheduled SnapMirror transfers, aborting ongoing SnapMirror transfers, breaking the replication relationship, stopping the source SVM, and starting the destination SVM.

```
= Make SVM destination volumes writeable
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/
```

You need to make SVM destination volumes writeable before you can serve data to clients. The procedure is largely identical to the procedure for volume replication, with one exception. If you set `-identity-preserve true` when you created the SVM replication relationship, you must stop the source SVM before activating the destination SVM.

About this task

For complete command syntax, see the man page.

In a disaster recovery scenario, you cannot perform a SnapMirror update from the source SVM to the disaster recovery destination SVM because your source SVM and its data will be inaccessible, and because updates since the last resync might be bad or corrupt.

Steps

- From the destination SVM or the destination cluster, stop scheduled transfers to the destination:

```
snapmirror quiesce -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example stops scheduled transfers between the source SVM `svm1` and the destination SVM `svm_backup`:

```
cluster_dst::> snapmirror quiesce -source-path svm1: -destination-path svm_backup:
```

- From the destination SVM or the destination cluster, stop ongoing transfers to the destination:

```
snapmirror abort -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example stops ongoing transfers between the source SVM `svm1` and the destination SVM `svm_backup`:

```
cluster_dst::> snapmirror abort -source-path svm1: -destination-path svm_backup:
```

- From the destination SVM or the destination cluster, break the replication relationship:

```
snapmirror break -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example breaks the relationship between the source SVM `svm1` and the destination SVM `svm_backup`:

```
cluster_dst::> snapmirror break -source-path svm1: -destination-path  
svm_backup:
```

4. If you set `-identity-preserve true` when you created the SVM replication relationship, stop the source SVM:

```
vserver stop -vserver SVM
```

The following example stops the source SVM `svm1`:

```
cluster_src::> vserver stop svm1
```

5. Start the destination SVM:

```
vserver start -vserver SVM
```

The following example starts the destination SVM `svm_backup`:

```
cluster_dst::> vserver start svm_backup
```

After you finish

Configure SVM destination volumes for data access, as described in [Configuring the destination volume for data access](#).

= Reactivate the source SVM

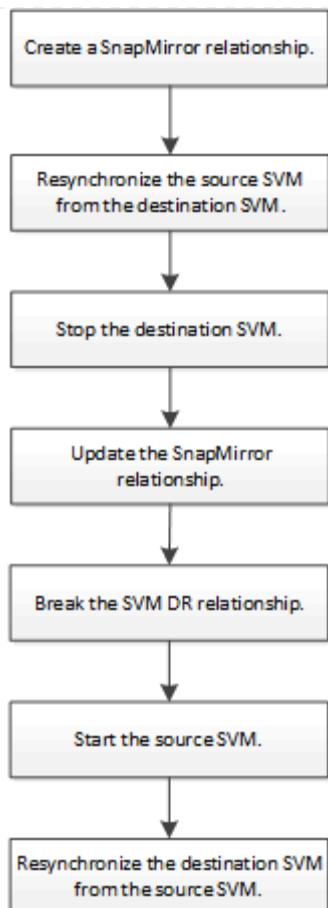

= Source SVM reactivation workflow

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

If the source SVM exists after a disaster, you can reactivate it and protect it by recreating the SVM disaster recovery relationship.

= Reactivate the original source SVM

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can reestablish the original data protection relationship between the source and destination SVM when you no longer need to serve data from the destination. The procedure is largely identical to the procedure for volume replication, with one exception. You must stop the destination SVM before reactivating the source SVM.

What you'll need

If you have increased the size of destination volume while serving data from it, before you reactivate the source volume, you should manually increase max-autosize on the original source volume to ensure it can grow sufficiently.

[When a destination volume grows automatically](#)

About this task

This procedure assumes that the baseline in the original source volume is intact. If the baseline is not intact, you must create and initialize the relationship between the volume you are serving data from and the original source volume before performing the procedure.

For complete command syntax on commands, see the man page.

Steps

- From the original source SVM or the original source cluster, create a reverse SVM DR relationship using the same configuration, policy, and identity-preserve setting as the original SVM DR relationship:

```
snapmirror create -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

The following example creates a relationship between the SVM from which you are serving data, `svm_backup`, and the original source SVM, `svm1`:

```
cluster_src::> snapmirror create -source-path svm_backup:  
-destination-path svm1:
```

- From the original source SVM or the original source cluster, run the following command to reverse the data protection relationship:

```
snapmirror resync -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

Although `resync` does not require a baseline transfer, it can be time-consuming. You might want to run the `resync` in off-peak hours.

The command fails if a common Snapshot copy does not exist on the source and destination. Use `snapmirror initialize` to reinitialize the relationship.

The following example reverses the relationship between the original source SVM, `svm1`, and the SVM from which you are serving data, `svm_backup`:

```
cluster_src::> snapmirror resync -source-path svm_backup:  
-destination-path svm1:
```

- When you are ready to reestablish data access to the original source SVM, stop the original destination SVM to disconnect any clients currently connected to the original destination SVM.

```
vserver stop -vserver SVM
```

The following example stops the original destination SVM which is currently serving data:

```
cluster_dst::> vserver stop svm_backup
```

- Verify that the original destination SVM is in the stopped state by using the `vserver show` command.

```

cluster_dst::> vserver show
          Admin      Operational Root
Vserver    Type     Subtype   State   State   Volume
Aggregate
-----
-----
svm_backup   data     default   stopped  stopped  rv
aggr1

```

- From the original source SVM or the original source cluster, run the following command to perform the final update of the reversed relationship to transfer all changes from the original destination SVM to the original source SVM:

```
snapmirror update -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example updates the relationship between the original destination SVM from which you are serving data, `svm_backup`, and the original source SVM, `svm1`:

```

cluster_src::> snapmirror update -source-path svm_backup:
                  -destination-path svm1:

```

- From the original source SVM or the original source cluster, run the following command to stop scheduled transfers for the reversed relationship:

```
snapmirror quiesce -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example stops scheduled transfers between the SVM you are serving data from, `svm_backup`, and the original SVM, `svm1`:

```

cluster_src::> snapmirror quiesce -source-path svm_backup:
                  -destination-path svm1:

```

- When the final update is complete and the relationship indicates "Quiesced" for the relationship status, run the following command from the original source SVM or the original source cluster to break the reversed relationship:

```
snapmirror break -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example breaks the relationship between the original destination SVM from which you were serving data, `svm_backup`, and the original source SVM, `svm1`:

```
cluster_src::> snapmirror break -source-path svm_backup:  
-destination-path svm1:
```

8. If the original source SVM was previously stopped, from the original source cluster, start the original source SVM:

```
vserver start -vserver SVM
```

The following example starts the original source SVM:

```
cluster_src::> vserver start svm1
```

9. From the original destination SVM or the original destination cluster, reestablish the original data protection relationship:

```
snapmirror resync -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example reestablishes the relationship between the original source SVM, `svm1`, and the original destination SVM, `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm1: -destination  
-path svm_backup:
```

10. From the original source SVM or the original source cluster, run the following command to delete the reversed data protection relationship:

```
snapmirror delete -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example deletes the reversed relationship between the original destination SVM, `svm_backup`, and the original source SVM, `svm1`:

```
cluster_src::> snapmirror delete -source-path svm_backup:  
-destination-path svm1:
```

- From the original destination SVM or the original destination cluster, release the reversed data protection relationship:

```
snapmirror release -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

The following example releases the reversed relationship between the original destination SVM, `svm_backup`, and the original source SVM, `svm1`

```
cluster_dst::> snapmirror release -source-path svm_backup:  
-destination-path svm1:
```

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

= Reactivate the original source SVM (FlexGroup volumes only)

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can reestablish the original data protection relationship between the source and destination SVM when you no longer need to serve data from the destination. To reactivate the original source SVM when you are using FlexGroup volumes, you need to perform some additional steps, including deleting the original SVM DR relationship and releasing the original relationship before you reverse the relationship. You also need to release the reversed relationship and recreate the original relationship before stopping scheduled transfers.

Steps

- From the original destination SVM or the original destination cluster, delete the original SVM DR relationship:

```
snapmirror delete -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

The following example deletes the original relationship between the original source SVM, `svm1`, and the original destination SVM, `svm_backup`:

```
cluster_dst::> snapmirror delete -source-path svm1: -destination-path svm_backup:
```

- From the original source SVM or the original source cluster, release the original relationship while keeping the Snapshot copies intact:

```
snapmirror release -source-path SVM: -destination-path SVM: -relationship-info-only true
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

The following example releases the original relationship between the original source SVM, svm1, and the original destination SVM, svm_backup.

```
cluster_src::> snapmirror release -source-path svm1: -destination-path svm_backup: -relationship-info-only true
```

- From the original source SVM or the original source cluster, create a reverse SVM DR relationship using the same configuration, policy, and identity-preserve setting as the original SVM DR relationship:

```
snapmirror create -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

The following example creates a relationship between the SVM from which you are serving data, svm_backup, and the original source SVM, svm1:

```
cluster_src::> snapmirror create -source-path svm_backup: -destination-path svm1:
```

- From the original source SVM or the original source cluster, run the following command to reverse the data protection relationship:

```
snapmirror resync -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

The command fails if a common Snapshot copy does not exist on the source and destination. Use `snapmirror initialize` to reinitialize the relationship.

The following example reverses the relationship between the original source SVM, `svm1`, and the SVM from which you are serving data, `svm backup`:

```
cluster_src::> snapmirror resync -source-path svm_backup:  
-destination-path svml1:
```

- When you are ready to reestablish data access to the original source SVM, stop the original destination SVM to disconnect any clients currently connected to the original destination SVM.

```
vserver stop -vserver SVM
```

The following example stops the original destination SVM which is currently serving data:

```
cluster_dst::> vserver stop svm_backup
```

- Verify that the original destination SVM is in the stopped state by using the `vservers show` command.

```
cluster_dst::> vserver show
                                         Admin      Operational Root
Vserver        Type     Subtype    State      State       Volume
Aggregate
-----
-----
svm_backup     data      default   stopped   stopped    rv
aqgr1
```

- From the original source SVM or the original source cluster, run the following command to perform the final update of the reversed relationship to transfer all changes from the original destination SVM to the original source SVM:

```
snapshotmirror update -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

The following example updates the relationship between the original destination SVM from which you are serving data.svm, backup, and the original source SVM, sym1:

```
cluster_src::> snapmirror update -source-path svm_backup:  
-destination-path svml:
```

8. From the original source SVM or the original source cluster, run the following command to stop scheduled transfers for the reversed relationship:

```
snapmirror quiesce -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

The following example stops scheduled transfers between the SVM you are serving data from, `svm_backup`, and the original SVM, `svm1`:

```
cluster_src::> snapmirror quiesce -source-path svm_backup:  
-destination-path svm1:
```

9. When the final update is complete and the relationship indicates "Quiesced" for the relationship status, run the following command from the original source SVM or the original source cluster to break the reversed relationship:

```
snapmirror break -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

The following example breaks the relationship between the original destination SVM from which you were serving data, `svm_backup`, and the original source SVM, `svm1`:

```
cluster_src::> snapmirror break -source-path svm_backup:  
-destination-path svm1:
```

10. If the original source SVM was previously stopped, from the original source cluster, start the original source SVM:

```
vserver start -vserver SVM
```

The following example starts the original source SVM:

```
cluster_src::> vserver start svm1
```

11. From the original source SVM or the original source cluster, delete the reversed SVM DR relationship:

```
snapmirror delete -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

The following example deletes the reversed relationship between the original destination SVM,

svm_backup, and the original source SVM, svm1:

```
cluster_src::> snapmirror delete -source-path svm_backup:  
-destination-path svm1:
```

- From the original destination SVM or the original destination cluster, release the reversed relationship while keeping the Snapshot copies intact:

```
snapmirror release -source-path SVM: -destination-path SVM: -relationship  
-info-only true
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

The following example releases the reversed relationship between the original destination SVM, svm_backup, and the original source SVM, svm1:

```
cluster_dst::> snapmirror release -source-path svm_backup:  
-destination-path svm1: -relationship-info-only true
```

- From the original destination SVM or the original destination cluster, recreate the original relationship. Use the same configuration, policy, and identity-preserve setting as the original SVM DR relationship:

```
snapmirror create -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

The following example creates a relationship between the original source SVM, svm1, and the original destination SVM, svm_backup:

```
cluster_dst::> snapmirror create -source-path svm1: -destination  
-path svm_backup:
```

- From the original destination SVM or the original destination cluster, reestablish the original data protection relationship:

```
snapmirror resync -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the -source-path and -destination-path options. See the example below.

The following example reestablishes the relationship between the original source SVM, svm1, and the original destination SVM, svm_backup:

```
cluster_dst::> snapmirror resync -source-path svm1: -destination  
-path svm_backup:
```

= Convert volume replication relationships to an SVM replication relationship
:icons: font
:relative_path: ./data-protection/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

You can convert replication relationships between volumes to a replication relationship between the storage virtual machines (SVMs) that own the volumes, provided that each volume on the source (except the root volume) is being replicated, and each volume on the source (including the root volume) has the same name as the volume on the destination.

About this task

Use the `volume rename` command when the SnapMirror relationship is idle to rename destination volumes if necessary.

Steps

1. From the destination SVM or the destination cluster, run the following command to resync the source and destination volumes:

```
snapmirror resync -source-path SVM:volume -destination-path SVM:volume  
-type DP|XDP -schedule schedule -policy policy
```

For complete command syntax, see the man page.

Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

The following example resyncs the relationship between the source volume `volA` on `svm1` and the destination volume `volA` on `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm1:volA -destination  
-path svm_backup:volA
```

2. Create an SVM replication relationship between the source and destination SVMs, as described in [Replicating SVM configurations](#).

You must use the `-identity-preserve true` option of the `snapmirror create` command when you create your replication relationship.

3. Stop the destination SVM:

```
vserver stop -vserver SVM
```

For complete command syntax, see the man page.

The following example stops the destination SVM `svm_backup`:

```
cluster_dst::> vserver stop svm_backup
```

4. From the destination SVM or the destination cluster, run the following command to resync the source and destination SVMs:

```
snapmirror resync -source-path SVM: -destination-path SVM: -type DP|XDP  
-schedule schedule -policy policy
```

For complete command syntax, see the man page.

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

The following example resyncs the relationship between the source SVM `svm1` and the destination SVM `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm1: -destination-path svm_backup:
```

= Delete an SVM replication relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use the `snapmirror delete` and `snapmirror release` commands to delete an SVM replication relationship. You can then delete unneeded destination volumes manually.

About this task

The `snapmirror release` command deletes any SnapMirror-created Snapshot copies from the source. You can use the `-relationship-info-only` option to preserve the Snapshot copies.

For complete command syntax on commands, see the man page.

Steps

1. Run the following command from the destination SVM or the destination cluster to break the replication relationship:

```
snapmirror break -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example breaks the relationship between the source SVM `svm1` and the destination SVM `svm_backup`:

```
cluster_dst::> snapmirror break -source-path svm1: -destination-path  
svm_backup:
```

- Run the following command from the destination SVM or the destination cluster to delete the replication relationship:

```
snapmirror delete -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example deletes the relationship between the source SVM `svm1` and the destination SVM `svm_backup`:

```
cluster_dst::> snapmirror delete -source-path svm1: -destination  
-path svm_backup:
```

- Run the following command from the source cluster or source SVM to release the replication relationship information from the source SVM:

```
snapmirror release -source-path SVM: -destination-path SVM:
```

You must enter a colon (:) after the SVM name in the `-source-path` and `-destination-path` options. See the example below.

The following example releases information for the specified replication relationship from the source SVM `svm1`:

```
cluster_src::> snapmirror release -source-path svm1: -destination  
-path svm_backup:
```

= Manage SnapMirror root volume replication

= Manage SnapMirror root volume replication overview

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

Every SVM in a NAS environment has a unique namespace. The SVM *root volume*, containing operating system and related information, is the entry point to the namespace hierarchy. To ensure that data remains accessible to clients in the event of a node outage or failover, you should create a load-sharing mirror copy of the SVM

root volume.

The main purpose of load-sharing mirrors for SVM root volumes is no longer for load sharing; instead, their purpose is for disaster recovery.

- If the root volume is temporarily unavailable, the load-sharing mirror automatically provides read-only access to root volume data.
- If the root volume is permanently unavailable, you can promote one of the load-sharing volumes to provide write access to root volume data.

= Create and initializing load-sharing mirror relationships

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You should create a load-sharing mirror (LSM) for each SVM root volume that serves NAS data in the cluster. You can create the LSM on any node other than the one containing the root volume, such as the partner node in an HA pair, or preferably in a different HA pair. For a two-node cluster, you should create the LSM on the partner of the node with the SVM root volume.

About this task

If you create an LSM on the same node, and the node is unavailable, you have a single point of failure, and you do not have a second copy to ensure the data remains accessible to clients. But when you create the LSM on a node other than the one containing the root volume, or on a different HA pair, your data is still accessible in the event of an outage.

For example, in a four-node cluster with a root volume on three nodes:

- For the root volume on HA 1 node 1, create the LSM on HA 2 node 1 or HA 2 node 2.
- For the root volume on HA 1 node 2, create the LSM on HA 2 node 1 or HA 2 node 2.
- For the root volume on HA 2 node 1, create the LSM on HA 1 node 1 or HA 1 node 2.

Steps

1. Create a destination volume for the LSM:

```
volume create -vserver SVM -volume volume -aggregate aggregate -type DP  
-size size
```

The destination volume should be the same or greater in size than the root volume.

It is a best practice to name the root and destination volume with suffixes, such as `_root` and `_m1`.

For complete command syntax, see the man page.

The following example creates a load-sharing mirror volume for the root volume `svm1_root` in `cluster_src`:

```
cluster_src:> volume create -vserver svml -volume svml_m1 -aggregate aggr_1 -size 1gb -state online -type DP
```

2. Create a replication job schedule, as described in [Creating a replication job schedule](#).
3. Create a load-sharing mirror relationship between the SVM root volume and the destination volume for the LSM:

```
snapmirror create -source-path SVM:volume|cluster://SVM/volume -destination-path SVM:volume|cluster://SVM/volume -type LS -schedule schedule
```

For complete command syntax, see the man page.

The following example creates a load-sharing mirror relationship between the root volume `svml_root` and the load-sharing mirror volume `svml_m1`:

```
cluster_src:> snapmirror create -source-path svml:svml_root -destination-path svml:svml_m1 -type LS -schedule hourly
```

The type attribute of the load-sharing mirror changes from `DP` to `LS`.

4. Initialize the load-sharing mirror:

```
snapmirror initialize-ls-set -source-path SVM:volume|cluster://SVM/volume
```

Initialization can be time-consuming. You might want to run the baseline transfer in off-peak hours.

For complete command syntax, see the man page.

The following example initializes the load-sharing mirror for the root volume `svml_root`:

```
cluster_src:> snapmirror initialize-ls-set -source-path svml:svml_root
```

= Update a load-sharing mirror relationship

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You should manually update a load-sharing mirror (LSM) relationship if you want changes on the root volume to be visible before the next scheduled update. For example, when a new volume is mounted on the root volume of the SVM, you should update the LSM relationship.

Step

1. Update a load-sharing mirror relationship manually:

```
snapmirror update-ls-set -source-path SVM:volume|cluster://SVM/volume
```

The following example updates the load-sharing mirror relationship for the root volume `svm1_root`:

```
cluster_src::> snapmirror update-ls-set -source-path svm1:svm1_root
```

= Promote a load-sharing mirror

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

If a root volume is permanently unavailable, you can promote the load-sharing mirror (LSM) volume to provide write access to root volume data.

What you'll need

You must use advanced privilege level commands for this task.

Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Promote an LSM volume:

```
snapmirror promote -destination-path SVM:volume|cluster://SVM/volume
```

For complete command syntax, see the man page.

The following example promotes the volume `svm1_m2` as the new SVM root volume:

```
cluster_src::*> snapmirror promote -destination-path svm1:svm1_m2
```

```
Warning: Promote will delete the offline read-write volume  
cluster_src://svm1/svm1_root and replace it with  
cluster_src://svm1/svm1_m2. Because the volume is offline,  
it is not possible to determine whether this promote will  
affect other relationships associated with this source.
```

```
Do you want to continue? {y|n}: y
```

Enter `y`. ONTAP makes the LSM volume a read/write volume, and deletes the original root volume if it is accessible.

The promoted root volume might not have all of the data that was in the original root volume if the last update did not occur recently.

3. Return to admin privilege level:

```
set -privilege admin
```

4. Rename the promoted volume following the naming convention you used for the root volume:

```
volume rename -vserver SVM -volume volume -newname new_name
```

The following example renames the promoted volume `svm1_m2` with the name `svm1_root`:

```
cluster_src::> volume rename -vserver svm11 -volume svm1_m2 -newname  
svm1_root
```

5. Protect the renamed root volume, as described in step 3 through step 4 in [Creating and initializing load-sharing mirror relationships](#).

= SnapMirror technical details

= Use path name pattern matching

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use pattern matching to specify the source and destination paths in `snapmirror` commands.

`snapmirror` commands use fully qualified path names in the following format: `vserver:volume`. You can abbreviate the path name by not entering the SVM name. If you do this, the `snapmirror` command assumes the local SVM context of the user.

Assuming that the SVM is called “`vserver1`” and the volume is called “`vol1`”, the fully qualified path name is `vserver1:vol1`.

You can use the asterisk (*) in paths as a wildcard to select matching, fully qualified path names. The following table provides examples of using the wildcard to select a range of volumes.

*	Matches all paths.
<code>vs*</code>	Matches all SVMs and volumes with SVM names beginning with <code>vs</code> .
<code>:*src</code>	Matches all SVMs with volume names containing the <code>src</code> text.
<code>:vol</code>	Matches all SVMs with volume names beginning with <code>vol</code> .

```

vs1::> snapmirror show -destination-path *:*dest*
Progress
Source           Destination   Mirror      Relationship  Total
Last
Path            Type    Path        State       Status      Progress
Healthy Updated
-----
----- vs1:sm_src2
          DP     vs2:sm_dest1
                           Snapmirrored  Idle
true      -

```

= Use extended queries to act on many SnapMirror relationships

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use *extended queries* to perform SnapMirror operations on many SnapMirror relationships at one time. For example, you might have multiple uninitialized SnapMirror relationships that you want to initialize using one command.

About this task

You can apply extended queries to the following SnapMirror operations:

- Initializing uninitialized relationships
- Resuming quiesced relationships
- Resynchronizing broken relationships
- Updating idle relationships
- Aborting relationship data transfers

Step

1. Perform a SnapMirror operation on many relationships:

```
snapmirror command {-state state} *
```

The following command initializes SnapMirror relationships that are in an Uninitialized state:

```
vs1::> snapmirror initialize {-state Uninitialized} *
```

= Ensure a common Snapshot copy in a mirror-vault deployment

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use the `snapmirror snapshot-owner create` command to preserve a labeled Snapshot copy on the secondary in a mirror-vault deployment. Doing so ensures that a common Snapshot copy exists for the update of the vault relationship.

About this task

If you use a combination mirror-vault fan-out or cascade deployment, you should keep in mind that updates will fail if a common Snapshot copy does not exist on the source and destination volumes.

This is never an issue for the mirror relationship in a mirror-vault fan-out or cascade deployment, since SnapMirror always creates a Snapshot copy of the source volume before it performs the update.

It might be an issue for the vault relationship, however, since SnapMirror does not create a Snapshot copy of the source volume when it updates a vault relationship. You need to use the `snapmirror snapshot-owner create` to ensure that there is at least one common Snapshot copy on both the source and destination of the vault relationship.

Steps

1. On the source volume, assign an owner to the labeled Snapshot copy you want to preserve:

```
snapmirror snapshot-owner create -vserver SVM -volume volume -snapshot  
snapshot -owner owner
```

The following example assigns ApplicationA as the owner of the `snap1` Snapshot copy:

```
clust1::> snapmirror snapshot-owner create -vserver vs1 -volume vol1  
-snapshot snap1 -owner ApplicationA
```

2. Update the mirror relationship, as described in [Updating a replication relationship manually](#).

Alternatively, you can wait for the scheduled update of the mirror relationship.

3. Transfer the labeled Snapshot copy to the vault destination:

```
snapmirror update -source-path SVM:volume|cluster://SVM/volume, ...  
-destination-path SVM:volume|cluster://SVM/volume, ... -source-snapshot  
snapshot
```

For complete command syntax, see the man page.

The following example transfers the `snap1` Snapshot copy

```
clust1::> snapmirror update -vserver vs1 -volume vol1  
-source-snapshot snap1
```

The labeled Snapshot copy will be preserved when the vault relationship is updated.

4. On the source volume, remove the owner from the labeled Snapshot copy:

```
snapmirror snapshot-owner delete -vserver SVM -volume volume -snapshot  
snapshot -owner owner
```

The following examples removes ApplicationA as the owner of the snap1 Snapshot copy:

```
clust1::> snapmirror snapshot-owner delete -vserver vs1 -volume vol1  
-snapshot snap1 -owner ApplicationA
```

= Compatible ONTAP versions for SnapMirror relationships

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You should verify that the source and destination volumes are running compatible ONTAP versions before creating a SnapMirror data protection relationship.

Version-independence is not supported for SVM replication.

== SnapMirror DR relationships

For SnapMirror relationships of type “DP” and policy type “async-mirror”:

In the following table, the column on the left indicates the ONTAP version on the source volume, and the top row indicates the ONTAP versions you can have on your destination volume.

SOURCE	DESTINATION	8.2	8.3	9.0	9.1	9.2	9.3	9.4	9.5	9.6	9.7	9.8	9.9.1	9.10.1
8.2	Yes	Yes	Yes	No	No									
8.3	No	Yes	Yes	Yes	No	No								
9.0	No	No	Yes	Yes	Yes	No	No							
9.1	No	No	No	Yes	Yes	Yes	No	No						
9.2	No	No	No	No	Yes	Yes	Yes	No	No	No	No	No	No	No
9.3	No	No	No	No	No	Yes	Yes	Yes	No	No	No	No	No	No
9.4	No	No	No	No	No	No	Yes	Yes	Yes	No	No	No	No	No
9.5	No	No	No	No	No	No	No	Yes	Yes	Yes	No	No	No	No
9.6	No	No	No	No	No	No	No	No	Yes	Yes	Yes	No	No	No

9.7	No	Yes	Yes	Yes	No									
9.8	No	Yes	Yes	Yes	Yes									
9.9.1	No	Yes	Yes	Yes										
9.10.1	No	No	No	Yes										

Interoperability is not bidirectional.

== Unified replication relationships

For SnapMirror relationships of type “XDP”, using on premises or Cloud Volumes ONTAP releases:

The asterisk (*) after the release version indicates a Cloud Volumes ONTAP-only release.

Table 2: Interoperability for ONTAP version 8.3.x and later

ONTAP version...	Interoperates with previous ONTAP versions...														
	8.3.x	8.3.2 P4	9.0	9.1	9.2	9.3	9.4	9.5	9.6	9.7	9.8	9.9.0*	9.9.1	9.10.0*	9.10.1
8.3.x	Yes	-	-	-	-	-	-	-	-	-	-	-	-	-	-
8.3.2 P4	Yes	Yes	-	-	-	-	-	-	-	-	-	-	-	-	-
9.0	Yes	Yes	Yes	-	-	-	-	-	-	-	-	-	-	-	-
9.1	Yes	Yes	Yes	Yes	-	-	-	-	-	-	-	-	-	-	-
9.2	No	Yes	Yes	Yes	Yes	-	-	-	-	-	-	-	-	-	-
9.3	No	No	Yes	Yes	Yes	Yes	-	-	-	-	-	-	-	-	-
9.4	No	No	Yes	Yes	No	Yes	Yes	-	-	-	-	-	-	-	-
9.5	No	No	No	Yes	No	Yes	Yes	Yes	-	-	-	-	-	-	-
9.6	No	No	No	Yes	No	Yes	No	Yes	Yes	-	-	-	-	-	-

9.7	No	No	No	No	No	Yes	No	Yes	Yes	Yes	-	-	-	-	-	-
9.8	No	No	No	No	No	Yes	No	Yes	Yes	Yes	Yes	-	-	-	-	-
9.9.0 *	No	No	No	No	No	No	No	Yes	Yes	Yes	Yes	-	-	-	-	-
9.9.1	No	No	No	No	No	No	No	Yes	Yes	Yes	Yes	Yes	Yes	-	-	-
9.10. 0*	No	No	No	No	No	No	No	Yes	Yes	Yes	Yes	No	Yes	Yes	-	-
9.10. 1	No	No	No	No	No	No	No	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	-

Locate the higher, more recent ONTAP version in the left column, and in the top row locate the lower ONTAP version to determine interoperability. Interoperability is bidirectional.

= SnapMirror limitations

:icons: font

:relative_path: ./data-protection/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

You should be aware of basic SnapMirror limitations before creating a data protection relationship.

- A destination volume can have only one source volume.

A source volume can have multiple destination volumes. The destination volume can be the source volume for any type of SnapMirror replication relationship.

- You can fan out a maximum of eight destination volumes from a single source volume.
- You cannot restore files to the destination of a SnapMirror DR relationship.
- Source or destination SnapVault volumes cannot be 32-bit.
- The source volume for a SnapVault relationship should not be a FlexClone volume.

The relationship will work, but the efficiency offered by FlexClone volumes will not be preserved.

= Archive and compliance using SnapLock technology

= Archive and compliance overview

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

You can use NetApp SnapLock technology to retain files in unmodified form for

regulatory and governance purposes. It shows you how to commit files and Snapshot copies to “write once, read many” (WORM) storage, and how to set retention periods for WORM-protected data.

You should use these procedures if you want to work with SnapLock in the following ways:

- You want to use the ONTAP command-line interface (CLI), not System Manager or an automated scripting tool.

A limited but important set of SnapLock technology is available in System Manager. You can install SnapLock licenses, set the Compliance Clock, create SnapLock aggregates and volumes, and configure SnapLock volumes.

- You want to create Compliance or Enterprise aggregates to host SnapLock audit log volumes on MetroCluster configurations, with the following limitation:
 - SnapLock Enterprise is supported on mirrored and unmirrored aggregates.
 - SnapLock Compliance is supported on unmirrored aggregates only.

All MetroCluster configurations support mirrored aggregates. See the [ONTAP release notes](#) to determine if your MetroCluster configuration supports unmirrored aggregates.

- You want to use SnapLock Enterprise aggregates with FabricPool.

Beginning with ONTAP 9.8, SnapLock Enterprise aggregates are supported with [FabricPool](#).

- You are not using SAN LUNs

SAN LUNs are not supported on SnapLock volumes. Although it is possible to move SAN LUNs onto a SnapLock volume using legacy technology, this is not a supported operation, nor is any other operation involving SAN LUNs on a SnapLock volume.

- You are not using SMTape.

SMTape is not supported by SnapLock.

- You are not creating Compliance aggregates for array LUNs.

SnapLock Compliance aggregates do not support array LUNs.

- You are not creating Compliance aggregates with the SyncMirror option.

SnapLock Compliance aggregates do not support SyncMirror plexes.

SSDs and Flash Pool aggregates are supported by SnapLock beginning with ONTAP 9.1.

= What SnapLock is

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

SnapLock is a high-performance compliance solution for organizations that use WORM storage to retain files in unmodified form for regulatory and governance

purposes. A single license entitles you to use SnapLock in strict *Compliance mode*, to satisfy external mandates like SEC Rule 17a-4, and a looser *Enterprise mode*, to meet internally mandated regulations for the protection of digital assets.

== Differences between Compliance and Enterprise modes

SnapLock Compliance and Enterprise modes differ mainly in the level at which each mode protects WORM files:

- Compliance-mode WORM files are protected at the disk level.
You cannot reinitialize a disk that contains Compliance-mode aggregates.
- Enterprise-mode WORM files are protected at the file level.

A related difference involves how strictly each mode manages file deletes:

- Compliance-mode WORM files cannot be deleted during the retention period.
- Enterprise-mode WORM files can be deleted during the retention period by the compliance administrator, using an audited *privileged delete* procedure.

After the retention period has elapsed, you are responsible for deleting any files you no longer need. Once a file has been committed to WORM, whether under Compliance or Enterprise mode, it cannot be modified, even after the retention period has expired.

You cannot move a WORM file during or after the retention period. You can copy a WORM file, but the copy will not retain its WORM characteristics.

The following table shows the differences between SnapLock Compliance and Enterprise modes:

Capability	SnapLock Compliance	SnapLock Enterprise
Privileged delete	No	Yes
Reinitialize disk	No	Yes
Destroy SnapLock aggregate and volume during retention period	No	Yes
Rename an aggregate or volume	No	Yes
Non-NetApp disks	No	Yes (with FlexArray Virtualization)
Use SnapLock volume for audit logging	Yes	Yes, beginning with ONTAP 9.5
Single-file SnapRestore	No	Yes
SnapRestore	No	Yes

FlexClone	You can clone SnapLock volumes, but you cannot clone files on a SnapLock volume.	You can clone SnapLock volumes, but you cannot clone files on a SnapLock volume.
LUNs	No	No
SMTape	No	No
MetroCluster configurations	<p>SnapLock Compliance or Enterprise aggregates are supported to host SnapLock audit log volumes on MetroCluster configurations, with the following limitation:</p> <ul style="list-style-type: none"> • SnapLock Enterprise is supported on mirrored and unmirrored aggregates. • SnapLock Compliance is supported only on unmirrored aggregates only. <p>All MetroCluster configurations support mirrored aggregates. See the ONTAP release notes to determine if your MetroCluster configuration supports unmirrored aggregates.</p> <p>ONTAP 9 Release Notes</p>	No
Support FabricPools on SnapLock aggregates	No	<p>Yes, beginning with ONTAP 9.8</p> <p> You should be aware that any data that FabricPool tiers to a public or private cloud is no longer protected by SnapLock because that data can be deleted by a cloud admin.</p>

== MetroCluster configurations and compliance clocks

MetroCluster configurations use two compliance clock mechanisms, the Volume Compliance Clock (VCC) and the System Compliance Clock (SCC). The VCC and SCC are available to all SnapLock configurations. When you create a new volume on a node, its VCC is initialized with the current value of the SCC on that node. After the volume is created, the volume and file retention time is always tracked

with the VCC.

When a volume is replicated to another site, its VCC is also replicated. When a volume switchover occurs, from Site A to Site B, for example, the VCC continues to be updated on Site B while the SCC on Site A halts when Site A goes offline.

When Site A is brought back online and the volume switchback is performed, the Site A SCC clock restarts while the VCC of the volume continues to be updated. Because the VCC is continuously updated, regardless of switchover and switchback operations, the file retention times do not depend on SCC clocks and do not stretch.

== Committing files to WORM

You can use an application to commit files to WORM over NFS or CIFS, or use the SnapLock autocommit feature to commit files to WORM automatically. You can use a *WORM appendable file* to retain data that is written incrementally, like log information.

== Data protection

SnapLock supports data protection methods that should satisfy most compliance requirements:

- You can use SnapLock for SnapVault to WORM-protect Snapshot copies on secondary storage.
- You can use SnapMirror to replicate WORM files to another geographic location for disaster recovery.

== Storage efficiency

Beginning with ONTAP 9.9.1, SnapLock supports storage efficiency features, such as data compaction, cross-volume-deduplication, and adaptive compression for SnapLock volumes and aggregates.

== 7-Mode Transition

You can use the Copy-Based Transition (CBT) feature of the 7-Mode Transition Tool to migrate SnapLock volumes from 7-Mode to ONTAP. The SnapLock mode of the destination volume, Compliance or Enterprise, must match the SnapLock mode of the source volume. You cannot use Copy-Free Transition (CFT) to migrate SnapLock volumes.

== Encryption

ONTAP offers both software- and hardware-based encryption technologies for ensuring that data at rest cannot be read if the storage medium is repurposed, returned, misplaced, or stolen.

Disclaimer: NetApp cannot guarantee that SnapLock-protected WORM files on self-encrypting drives or volumes will be retrievable if the authentication key is lost or if the number of failed authentication attempts exceeds the specified limit and results in the drive being permanently locked. You are responsible for ensuring against authentication failures.

Beginning with ONTAP 9.2, encrypted volumes are supported on SnapLock aggregates.

= SnapLock workflow

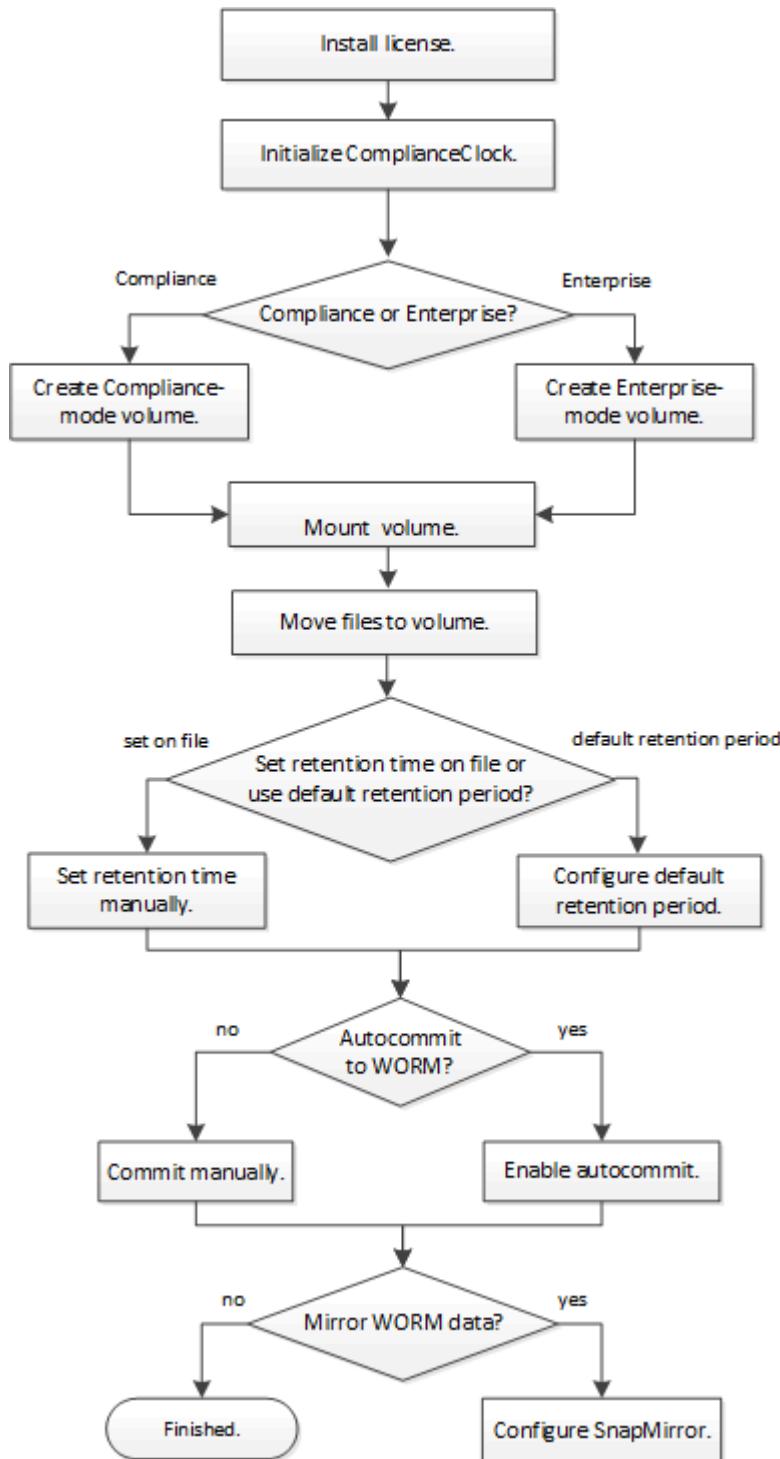

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You specify which SnapLock mode you want to use, Compliance or Enterprise, when

you create a SnapLock volume. You typically use a file archiving application to move files from primary storage to the SnapLock volume.

= Configure SnapLock

= Install the license

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

A SnapLock license entitles you to use both SnapLock Compliance mode and

SnapLock Enterprise mode. SnapLock licenses are issued on a per-node basis. You must install a license for each node that hosts a SnapLock aggregate.

What you'll need

You must be a cluster administrator to perform this task.

About this task

You should have received the SnapLock license keys from your sales representative.

Steps

1. Install the SnapLock license for a node:

```
system license add -license-code license_key
```

The following command installs the license with the key AAAAAAAAAAAAAAAAAAAAAA.

```
cluster1::> system license add -license-code  
AAAAAAAAAAAAAAAAAAAAA
```

2. Repeat the previous step for each node license.

= Initialize the ComplianceClock

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

The SnapLock ComplianceClock ensures against tampering that might alter the retention period for WORM files. You must initialize the *system ComplianceClock* on each node that hosts a SnapLock aggregate. Once you initialize the ComplianceClock on a node, you cannot initialize it again.

What you'll need

- You must be a cluster administrator to perform this task.
- The SnapLock license must be installed on the node.

About this task

The time on the system ComplianceClock is inherited by the *volume ComplianceClock*, which controls the retention period for WORM files on the volume. The volume ComplianceClock is initialized automatically when you create a new SnapLock volume.

The initial setting of the ComplianceClock is based on the current system clock. For that reason, you should verify that the system time and time zone are correct before initializing the ComplianceClock. Once you initialize the ComplianceClock on a node, you cannot initialize it again.

Steps

1. Initialize the system ComplianceClock:

```
snaplock compliance-clock initialize -node node_name
```

The following command initializes the system ComplianceClock on node1:

```
cluster1::> snaplock compliance-clock initialize -node node1
```

- When prompted, confirm that the system clock is correct and that you want to initialize the ComplianceClock:

Warning: You are about to initialize the secure ComplianceClock of the node "node1" to the current value of the node's system clock. This procedure can be performed only once on a given node, so you should ensure that the system time is set correctly before proceeding.

The current node's system clock is: Mon Apr 25 06:04:10 GMT 2016

Do you want to continue? (y|n): y

- Repeat this procedure for each node that hosts a SnapLock aggregate.

```
= Create a SnapLock aggregate
:icons: font
:relative_path: ./snaplock/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/
```

You use the volume -snaplock-type option to specify a Compliance or Enterprise SnapLock volume type. For releases earlier than ONTAP 9.10.1, you must create a separate SnapLock aggregate. Beginning with ONTAP 9.10.1, SnapLock and non-SnapLock volumes can exist on the same aggregate; therefore, you are no longer required to create a separate SnapLock aggregate if you are using ONTAP 9.10.1.

What you'll need

- You must be a cluster administrator to perform this task.
- The SnapLock license must be installed on the node.
- The ComplianceClock on the node must be initialized.
- If you have partitioned the disks as "root", "data1", and "data2", you must ensure that spare disks are available.

Upgrade considerations

When upgrading to ONTAP 9.10.1, existing SnapLock and non-SnapLock aggregates are upgraded to support the existence of both SnapLock and non-SnapLock volumes; however, the existing SnapLock volume attributes are not automatically updated. For example, data-compaction, cross-volume-dedupe, and cross-volume-background-dedupe fields remain unchanged. New SnapLock volumes created on existing aggregates have the same default values as non-SnapLock volumes, and the default values for new volumes and aggregates are platform dependent.

Revert considerations

If you need to revert to an ONTAP version earlier than 9.10.1, you must move all SnapLock Compliance, SnapLock Enterprise, and SnapLock volumes to their own SnapLock aggregates.

About this task

- You cannot create Compliance aggregates for FlexArray LUNs, but SnapLock Compliance aggregates are supported with FlexArray LUNs.
- You cannot create Compliance aggregates with the SyncMirror option.
- You can create mirrored Compliance aggregates in a MetroCluster configuration only if the aggregate is used to host SnapLock audit log volumes.

In a MetroCluster configuration, SnapLock Enterprise is supported on mirrored and unmirrored aggregates. SnapLock Compliance is supported only on unmirrored aggregates.

Steps

1. Create a SnapLock aggregate:

```
storage aggregate create -aggregate aggregate_name -node node_name  
-diskcount number_of_disks -snaplock-type compliance|enterprise
```

The man page for the command contains a complete list of options.

The following command creates a SnapLock Compliance aggregate named aggr1 with three disks on node1:

```
cluster1::> storage aggregate create -aggregate aggr1 -node node1  
-diskcount 3 -snaplock-type compliance
```

= Create a SnapLock volume

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You must create a SnapLock volume for the files or Snapshot copies that you want to commit to the WORM state. Beginning with ONTAP 9.10.1, any volume you create, regardless of the aggregate type, is created by default as a non-SnapLock volume. You must use the `-snaplock-type` option to explicitly create a SnapLock volume by specifying either Compliance or Enterprise as the SnapLock type. By default, the SnapLock type is set to `non-snaplock`.

What you'll need

- The SnapLock aggregate must be online.
- The SnapLock license must be installed on the node.
- The ComplianceClock on the node must be initialized.

About this task

With the proper SnapLock permissions, you can destroy or rename an Enterprise volume at any time. You

cannot destroy a Compliance volume until the retention period has elapsed. You can never rename a Compliance volume.

You can clone SnapLock volumes, but you cannot clone files on a SnapLock volume. The clone volume will be of the same SnapLock type as the parent volume.

LUNs are not supported on SnapLock volumes. Although it is possible to move LUNs onto a SnapLock volume using legacy technology, this is not a supported operation, nor is any other operation involving LUNs on a SnapLock volume.

Steps

1. Create a SnapLock volume:

```
volume create -vserver SVM_name -volume volume_name -aggregate  
aggregate_name -snaplock-type compliance|enterprise
```

For a complete list of options, see the man page for the command. The following options are not available for SnapLock volumes: -nvfail, -atime-update, -is-autobalance-eligible, -space-mgmt-try-first, and vmalign.

The following command creates a SnapLock Compliance volume named vol1 on aggr1 on vs1:

```
cluster1::> volume create -vserver vs1 -volume vol1 -aggregate aggr1  
-snaplock-type compliance
```

= Mount a SnapLock volume

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can mount a SnapLock volume to a junction path in the SVM namespace for NAS client access.

What you'll need

The SnapLock volume must be online.

About this task

- You can mount a SnapLock volume only under the root of the SVM.
- You cannot mount a regular volume under a SnapLock volume.

Steps

1. Mount a SnapLock volume:

```
volume mount -vserver SVM_name -volume volume_name -junction-path path
```

For a complete list of options, see the man page for the command.

The following command mounts a SnapLock volume named vol1 to the junction path /sales in the vs1 namespace:

```
cluster1::> volume mount -vserver vs1 -volume vol1 -junction-path  
/sales
```

= Set the retention time

= Set the retention time overview

:icons: font

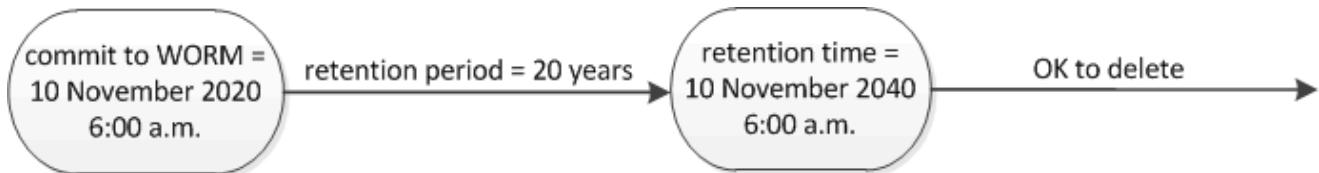

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can set the retention time for a file explicitly, or you can use the default retention period for the volume to derive the retention time. Unless you set the retention time explicitly, SnapLock uses the default retention period to calculate the retention time.

== About retention period and retention time

The *retention period* for a WORM file specifies the length of time the file must be retained after it is committed to the WORM state. The *retention time* for a WORM file is the time after which the file no longer needs to be retained. A retention period of 20 years for a file committed to the WORM state on 10 November 2020 6:00 a.m., for example, would yield a retention time of 10 November 2040 6:00 a.m.

Beginning with ONTAP 9.10.1, you can set a retention time up to October 26, 3058 and a retention period up to 100 years. When you extend retention dates, older policies are converted automatically. In ONTAP 9.9.1 and earlier releases, unless you set the default retention period to infinite, the maximum supported retention time is January 19 2071 (GMT).

== Important revert considerations

ONTAP prevents you from reverting a cluster from ONTAP 9.10.1 to an earlier ONTAP version when there are any files with a retention period later than “January 19, 2071 8:44:07 AM”.

== Understanding the default retention periods

A SnapLock Compliance or Enterprise volume has four retention periods:

- Minimum retention period (`min`), with a default of 0
- Maximum retention period (`max`), with a default of 30 years
- Default retention period, with a default equal to `min` for both Compliance mode and Enterprise mode beginning with ONTAP 9.10.1. In ONTAP releases earlier than ONTAP 9.10.1, the default retention period depends on the mode:
 - For Compliance mode, the default is equal to `max`.
 - For Enterprise mode, the default is equal to `min`.

- Unspecified retention period.

Beginning with ONTAP 9.8, you can set the retention period on files in a volume to unspecified, to enable the file to be retained until you set an absolute retention time. You can set a file with absolute retention time to unspecified retention and back to absolute retention as long as the new absolute retention time is later than the absolute time you previously set.

So, if you do not set the retention time explicitly before committing a Compliance-mode file to the WORM state, and you do not modify the defaults, the file will be retained for 30 years. Similarly, if you do not set the retention time explicitly before committing an Enterprise-mode file to the WORM state, and you do not modify the defaults, the file will be retained for 0 years, or, effectively, not at all.

= Set the retention time for a file explicitly

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can set the retention time for a file explicitly by modifying its last access time. You can use any suitable command or program over NFS or CIFS to modify the last access time.

About this task

After a file has been committed to WORM, you can extend but not shorten the retention time. The retention time is stored in the `atime` field for the file.

You cannot explicitly set the retention time of a file to `infinite`. That value is only available when you use the default retention period to calculate the retention time.

Steps

1. Use a suitable command or program to modify the last access time for the file whose retention time you want to set.

In a UNIX shell, use the following command to set a retention time of 21 November 2020 6:00 a.m. on a file named `document.txt`:

```
touch -a -t 202011210600 document.txt
```

You can use any suitable command or program to modify the last access time in Windows.

= Set the default retention period

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use the `volume snaplock modify` command to set the default retention period for files on a SnapLock volume.

What you'll need

The SnapLock volume must be online.

About this task

The following table shows the possible values for the default retention period option:

The default retention period must be greater than or equal to (\geq) the minimum retention period and less than or equal to (\leq) the maximum retention period.

Value	Unit	Notes
0 - 65535	seconds	
0 - 24	hours	
0 - 365	days	
0 - 12	months	
0 - 70	years	
max	-	Use the maximum retention period.
min	-	Use the minimum retention period.
infinite	-	Retain the files forever.
unspecified	-	Retain the files until an absolute retention period is set.

The values and ranges for the maximum and minimum retention periods are identical, except for `max` and `min`, which are not applicable. For more information about this task, see [Set the retention time overview](#).

You can use the `volume snaplock show` command to view the retention period settings for the volume. For more information, see the man page for the command.

After a file has been committed to the WORM state, you can extend but not shorten the retention period.

Steps

1. Set the default retention period for files on a SnapLock volume:

```
volume snaplock modify -vserver SVM_name -volume volume_name -default
-retention-period default_retention_period -minimum-retention-period
min_retention_period -maximum-retention-period max_retention_period
```

For a complete list of options, see the man page for the command.

The following examples assume that the minimum and maximum retention periods have not been modified previously.

The following command sets the default retention period for a Compliance or Enterprise volume to 20 days:

```
cluster1::> volume snaplock modify -vserver vs1 -volume vol1  
-default-retention-period 20days
```

The following command sets the default retention period for a Compliance volume to 70 years:

```
cluster1::> volume snaplock modify -vserver vs1 -volume vol1  
-maximum-retention-period 70years
```

The following command sets the default retention period for an Enterprise volume to 10 years:

```
cluster1::> volume snaplock modify -vserver vs1 -volume vol1  
-default-retention-period max -maximum-retention-period 10years
```

The following commands set the default retention period for an Enterprise volume to 10 days:

```
cluster1::> volume snaplock modify -vserver vs1 -volume vol1  
-minimum-retention-period 10days  
cluster1::> volume snaplock modify -vserver vs1 -volume vol1  
-default-retention-period min
```

The following command sets the default retention period for a Compliance volume to infinite:

```
cluster1::> volume snaplock modify -vserver vs1 -volume vol1  
-default-retention-period infinite -maximum-retention-period  
infinite
```

= Verify SnapLock settings

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use the `volume file fingerprint start` and `volume file fingerprint dump` commands to view key information about files and volumes, including the file type (regular, WORM, or WORM appendable), the volume expiration date, and so forth.

Steps

1. Generate a file fingerprint:

```
volume file fingerprint start -vserver SVM_name -file file_path
```

```
svm1::> volume file fingerprint start -vserver svm1 -file /vol/sle/vol/f1
File fingerprint operation is queued. Run "volume file fingerprint show -session-id 16842791" to view the fingerprint session status.
```

The command generates a session ID that you can use as input to the `volume file fingerprint dump` command.

You can use the `volume file fingerprint show` command with the session ID to monitor the progress of the fingerprint operation. Make sure that the operation has completed before attempting to display the fingerprint.

2. Display the fingerprint for the file:

```
volume file fingerprint dump -session-id session_ID
```

```
svm1::> volume file fingerprint dump -session-id 33619976
Vserver:svm1
Session-ID:33619976
Volume:slc_vol
Path:/vol/slcslc_vol/f1

= Reset the ComplianceClock for an NTP-configured system

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..../media/

When the SnapLock secure clock daemon detects a skew beyond the threshold, the system time is used to reset both the system and volume ComplianceClocks.

What you'll need

- This feature is available only at the advanced privilege level.
- You must be a cluster administrator to perform this task.
- The SnapLock license must be installed on the node.
- This feature is available only for Cloud Volumes ONTAP, ONTAP Select, and VSIM platforms.

About this task

When the SnapLock secure clock daemon detects a skew beyond the threshold, the system time is used

to reset both the system and volume ComplianceClocks. A period of 24 hours is set as the skew threshold. This means that the system ComplianceClock is synchronized to the system clock only if the skew is more than a day old.

The SnapLock secure clock daemon detects a skew and changes the ComplianceClock to the system time. Any attempt at modifying the system time to force the ComplianceClock to synchronize to the system time fails, since the ComplianceClock synchronizes to the system time only if the system time is synchronized with the NTP time.

Steps

1. Enable the SnapLock ComplianceClock time synchronization feature when an NTP server is configured:

```
snaplock compliance-clock ntp
```

The following command enables the system ComplianceClock time synchronization feature:

```
cluster1::>* snaplock compliance-clock ntp modify -is-sync-enabled  
true
```

2. When prompted, confirm that the configured NTP servers are trusted and that the communications channel is secure to enable the feature:
3. Check that the feature is enabled:

```
snaplock compliance-clock ntp show
```

The following command checks that the system ComplianceClock time synchronization feature is enabled:

```
cluster1::>* snaplock compliance-clock ntp show
```

```
Enable clock sync to NTP system time: true
```

= Commit files to WORM

= Commit files to WORM manually

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You commit a file to WORM manually by making the file read-only. You can use any suitable command or program over NFS or CIFS to change the read-write attribute of a file to read-only.

What you'll need

- The file you want to commit must reside on a SnapLock volume.
- The file must be writable.

About this task

The volume ComplianceClock time is written to the `ctime` field of the file when the command or program is executed. The ComplianceClock time determines when the retention time for the file has been reached.

Steps

1. Use a suitable command or program to change the read-write attribute of a file to read-only.

In a UNIX shell, use the following command to make a file named `document.txt` read-only:

```
chmod -w document.txt
```

In a Windows shell, use the following command to make a file named `document.txt` read-only:

```
attrib +r document.txt
```

= Autocommit files to WORM

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

The SnapLock autocommit feature enables you to commit files to WORM automatically.

What you'll need

- The files you want to autocommit must reside on a SnapLock volume.
- The SnapLock volume must be online.
- The SnapLock volume must be a read-write volume.

The SnapLock autocommit feature scans through all of the files in the volume and commits a file if it meets the autocommit requirement. There might be a time interval between when the file is ready for autocommit and when it is actually committed by the SnapLock autocommit scanner. However, the file is still protected from modifications and deletion by the file system as soon as it is eligible for autocommit.

About this task

The *autocommit period* specifies the amount of time that files must remain unchanged before they are autocommitted. Changing a file before the autocommit period has elapsed restarts the autocommit period for the file.

The following table shows the possible values for the autocommit period:

Value	Unit	Notes
none	-	The default.
5 - 5256000	minutes	-

Value	Unit	Notes
1 - 87600	hours	-
1 - 3650	days	-
1 - 120	months	-
1 - 10	years	-

The minimum value is 5 minutes and the maximum value is 10 years.

Steps

- Autocommit files on a SnapLock volume to WORM:

```
volume snaplock modify -vserver SVM_name -volume volume_name -autocommit
-autocommit-period autocommit_period
```

For a complete list of options, see the man page for the command.

The following command autocommits the files on volume vol1 of SVM vs1, as long as the files remain unchanged for 5 hours:

```
cluster1::>volume snaplock modify -vserver vs1 -volume vol1
-autocommit-period 5hours
```

= Use a command or program to create a WORM appendable file

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use any suitable command or program over NFS or CIFS to create a WORM appendable file. A WORM appendable file retains data written incrementally, like log entries. Data is appended to the file in 256 KB chunks. As each chunk is written, the previous chunk becomes WORM-protected. You cannot delete the file until the retention period has elapsed.

What you'll need

The WORM appendable file must reside on a SnapLock volume.

About this task

Data does not have to be written sequentially to the active 256 KB chunk. When data is written to byte $n \times 256\text{KB} + 1$ of the file, the previous 256 KB segment becomes WORM-protected.

Steps

- Use a suitable command or program to create a zero-length file with the desired retention time.

In a UNIX shell, use the following command to set a retention time of 21 November 2020 6:00 a.m. on a zero-length file named document.txt:

```
touch -a -t 202011210600 document.txt
```

2. Use a suitable command or program to change the read-write attribute of the file to read-only.

In a UNIX shell, use the following command to make a file named document.txt read-only:

```
chmod 444 document.txt
```

3. Use a suitable command or program to change the read-write attribute of the file back to writable.

This step is not deemed a compliance risk because there is no data in the file.

In a UNIX shell, use the following command to make a file named document.txt writable:

```
chmod 777 document.txt
```

4. Use a suitable command or program to start writing data to the file.

In a UNIX shell, use the following command to write data to document.txt:

```
echo test data >> document.txt
```

Change the file permissions back to read-only when you no longer need to append data to the file.

= Use volume append mode to create WORM appendable files

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

Beginning with ONTAP 9.3, you can use the SnapLock *volume append mode* (VAM) feature to create WORM appendable files by default. A WORM appendable file retains data written incrementally, like log entries. Data is appended to the file in 256 KB chunks. As each chunk is written, the previous chunk becomes WORM-protected. You cannot delete the file until the retention period has elapsed.

What you'll need

- The WORM appendable file must reside on a SnapLock volume.
- The SnapLock volume must be unmounted and empty of Snapshot copies and user-created files.

About this task

Data does not have to be written sequentially to the active 256 KB chunk. When data is written to byte $n \times 256\text{KB} + 1$ of the file, the previous 256 KB segment becomes WORM-protected.

If you specify an autocommit period for the volume, WORM appendable files that are not modified for a period greater than the autocommit period are committed to WORM.

VAM is not supported on SnapLock audit log volumes.

Steps

1. Enable VAM:

```
volume snaplock modify -vserver SVM_name -volume volume_name -is-volume  
-append-mode-enabled true|false
```

For a complete list of options, see the man page for the command.

The following command enables VAM on volume `vol1` of SVM`vs1`:

```
cluster1::>volume snaplock modify -vserver vs1 -volume vol1 -is  
-volume-append-mode-enabled true
```

2. Use a suitable command or program to create files with write permissions.

The files are WORM-appendable by default.

= Commit Snapshot copies to WORM
:icons: font
:relative_path: ./snaplock/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use SnapLock for SnapVault to WORM-protect Snapshot copies on secondary storage. You perform all of the basic SnapLock tasks on the SnapVault destination. The destination volume is automatically mounted read-only, so there is no need to explicitly commit the Snapshot copies to WORM; therefore, creating scheduled Snapshot copies on the destination volume using SnapMirror policies is not supported.

What you'll need

- The source cluster must be running ONTAP 8.2.2 or later.
- The source and destination aggregates must be 64-bit.
- The source volume cannot be a SnapLock volume.
- The source and destination volumes must be created in peered clusters with peered SVMs.

For more information, see [Cluster Peering](#).

- If volume autogrow is disabled, the free space on the destination volume must be at least five percent more than the used space on the source volume.

About this task

The source volume can use NetApp or non-NetApp storage. For non-NetApp storage, you must use FlexArray Virtualization.

You cannot rename a Snapshot copy that is committed to the WORM state.

You can clone SnapLock volumes, but you cannot clone files on a SnapLock volume.

LUNs are not supported on SnapLock volumes. Although it is possible to move LUNs onto a SnapLock volume using legacy technology, this is not a supported operation, nor is any other operation involving LUNs on a SnapLock volume.

For MetroCluster configurations, you should be aware of the following:

- You can create a SnapVault relationship only between sync-source SVMs, not between a sync-source SVM and a sync-destination SVM.
- You can create a SnapVault relationship from a volume on a sync-source SVM to a data-serving SVM.
- You can create a SnapVault relationship from a volume on a data-serving SVM to a DP volume on a sync-source SVM.

The following illustration shows the procedure for initializing a SnapVault relationship:

Steps

1. Identify the destination cluster.
2. On the destination cluster, install the SnapLock license, initialize the ComplianceClock, and create a SnapLock aggregate, as described in [Configure SnapLock](#).
3. On the destination cluster, create a SnapLock destination volume of type DP that is either the same or greater in size than the source volume:

```
volume create -vserver SVM_name -volume volume_name -aggregate  
aggregate_name -type DP -size size
```

The SnapLock mode, Compliance or Enterprise, is inherited from the aggregate. Version-flexible destination volumes are not supported. The language setting of the destination volume must match the language setting of the source volume.

The following command creates a 2 GB SnapLock Compliance volume named dstvolB in SVM2 on the aggregate node01_aggr:

```
cluster2::> volume create -vserver SVM2 -volume dstvolB -aggregate  
node01_aggr -type DP -size 2GB
```

4. On the destination cluster, set the default retention period, as described in [Set the default retention period](#).

A SnapLock volume that is a vault destination has a default retention period assigned to it. The value for this period is initially set to a minimum of 0 years for SnapLock Enterprise volumes and a maximum of 30 years for SnapLock Compliance volumes. Each NetApp Snapshot copy is committed with this default retention period at first. The retention period can be extended later, if needed. For more information, see [Set retention time overview](#).

5. [Create a new replication relationship](#) between the non-SnapLock source and the new SnapLock destination you created in Step 3.

This example creates a new SnapMirror relationship with destination SnapLock volume `dstvolB` using a policy of `XDPDefault` to vault Snapshot copies labeled daily and weekly on an hourly schedule:

```
cluster2::> snapmirror create -source-path SVM1:srcvolA -destination-path SVM2:dstvolB -vserver SVM2 -policy XDPDefault -schedule hourly
```

[Create a custom replication policy](#) or a [custom schedule](#) if the available defaults are not suitable.

6. On the destination SVM, initialize the SnapVault relationship created in Step 5:

```
snapmirror initialize -destination-path destination_path
```

The following command initializes the relationship between the source volume `srcvolA` on SVM1 and the destination volume `dstvolB` on SVM2:

```
cluster2::> snapmirror initialize -destination-path SVM2:dstvolB
```

7. After the relationship is initialized and idle, use the `snapshot show` command on the destination to verify the SnapLock expiry time applied to the replicated Snapshot copies.

This example lists the Snapshot copies on volume `dstvolB` that have the SnapMirror label and the SnapLock expiration date:

```
cluster2::> snapshot show -vserver SVM2 -volume dstvolB -fields snapmirror-label, snaplock-expiry-time
```

[Cluster and SVM peering](#)

[Volume backup using SnapVault](#)

= Mirror WORM files

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use SnapMirror to replicate WORM files to another geographic location for disaster recovery and other purposes. Both the source volume and destination volume must be configured for SnapLock, and both volumes must have the same SnapLock mode, Compliance or Enterprise. All key SnapLock properties of the volume and files are replicated.

Prerequisites

The source and destination volumes must be created in peered clusters with peered SVMs. For more information, see [Cluster and SVM peering](#).

About this task

- Beginning with ONTAP 9.5, you can replicate WORM files with the XDP (extended data protection) type SnapMirror relationship rather than the DP (data protection) type relationship. XDP mode is ONTAP version-independent, and is able to differentiate files stored in the same block, making it much easier to resync replicated Compliance-mode volumes. For information on how to convert an existing DP-type relationship to an XDP-type relationship, see [Data Protection](#).
- A resync operation on a DP type SnapMirror relationship fails for a Compliance-mode volume if SnapLock determines that it will result in a loss of data. If a resync operation fails, you can use the `volume clone create` command to make a clone of the destination volume. You can then resync the source volume with the clone.
- A SnapMirror relationship of type XDP between SnapLock compliant volumes supports a resync after a break even if data on the destination has diverged from the source post the break.

On a resync, when data divergence is detected between the source and the destination beyond the common snapshot, a new snapshot is cut on the destination to capture this divergence. The new snapshot and the common snapshot are both locked with a retention time as follows:

- The volume expiry time of the destination
- If the volume expiry time is in the past or has not been set, then the snapshot is locked for a period of 30 days
- If the destination has legal-holds, the actual volume expiry period is masked and shows up as ‘indefinite’, however the snapshot is locked for the duration of the actual volume expiry period.

If the destination volume has an expiry period that is later than the source, the destination expiry period is retained and will not be overwritten by the expiry period of the source volume post the resync.

If the destination has legal-holds placed on it that differ from the source, a resync is not allowed. The source and destination must have identical legal-holds or all legal-holds on the destination must be released before a resync is attempted.

A locked snapshot on the destination volume created to capture the divergent data can be copied to the source by running the `snapmirror update -s` `snapshot` command. The snapshot once copied will continue to be locked at the source as well.

- SVM data protection relationships are not supported.
- Load-sharing data protection relationships are not supported.

The following illustration shows the procedure for initializing a SnapMirror relationship:

Steps

1. Identify the destination cluster.
2. On the destination cluster, install the SnapLock license, initialize the ComplianceClock, and create a SnapLock aggregate.
3. On the destination cluster, create a SnapLock destination volume of type DP that is either the same size as or greater in size than the source volume:

```
volume create -vserver SVM_name -volume volume_name -aggregate
aggregate_name -type DP -size size
```

The SnapLock mode—Compliance or Enterprise—is inherited from the aggregate. Version-flexible destination volumes are not supported. The language setting of the destination volume must match the language setting of the source volume.

The following command creates a 2 GB SnapLock Compliance volume named dstvolB in SVM2 on the aggregate node01_aggr:

```
cluster2::> volume create -vserver SVM2 -volume dstvolB -aggregate
node01_aggr -type DP -size 2GB
```

4. On the destination SVM, create a SnapMirror policy:

```
snapmirror policy create -vserver SVM_name -policy policy_name
```

The following command creates the SVM-wide policy SVM1-mirror:

```
SVM2::> snapmirror policy create -vserver SVM2 -policy SVM1-mirror
```

5. On the destination SVM, create a SnapMirror schedule:

```
job schedule cron create -name schedule_name -dayofweek day_of_week -hour
hour -minute minute
```

The following command creates a SnapMirror schedule named weekendcron:

```
SVM2::> job schedule cron create -name weekendcron -dayofweek
"Saturday, Sunday" -hour 3 -minute 0
```

6. On the destination SVM, create a SnapMirror relationship:

```
snapmirror create -source-path source_path -destination-path
destination_path -type XDP|DP -policy policy_name -schedule schedule_name
```

The following command creates a SnapMirror relationship between the source volume srcvolA on SVM1 and the destination volume dstvolB on SVM2, and assigns the policy SVM1-mirror and the schedule weekendcron:

```
SVM2::> snapmirror create -source-path SVM1:srcvolA -destination-path SVM2:dstvolB -type XDP -policy SVM1-mirror -schedule weekendcron
```

The XDP type is available in ONTAP 9.5 and later. You must use the DP type in ONTAP 9.4 and earlier.

7. On the destination SVM, initialize the SnapMirror relationship:

```
snapmirror initialize -destination-path destination_path
```

The initialization process performs a *baseline transfer* to the destination volume. SnapMirror makes a Snapshot copy of the source volume, then transfers the copy and all the data blocks that it references to the destination volume. It also transfers any other Snapshot copies on the source volume to the destination volume.

The following command initializes the relationship between the source volume `srcvolA` on SVM1 and the destination volume `dstvolB` on SVM2:

```
SVM2::> snapmirror initialize -destination-path SVM2:dstvolB
```

[Cluster and SVM peering](#)

[Volume disaster recovery preparation](#)

[Data protection](#)

= Create an audit log

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You must create a SnapLock-protected audit log before performing a privileged delete or SnapLock volume move. The audit log records the creation and deletion of SnapLock administrator accounts, modifications to the log volume, whether privileged delete is enabled, privileged delete operations, and SnapLock volume move operations.

What you'll need

You must be a cluster administrator to create a SnapLock aggregate.

About this task

You cannot delete an audit log until the log file retention period has elapsed. You cannot modify an audit log even after the retention period has elapsed.

 In ONTAP 9.4 and earlier, you cannot use a SnapLock Enterprise volume for audit logging. You must use a SnapLock Compliance volume. In ONTAP 9.5 and later, you can use either a SnapLock Enterprise volume or a SnapLock Compliance volume for audit logging. In all cases, the audit log volume must be mounted at the junction path `/snaplock_audit_log`. No other volume can use this junction path.

You can find the SnapLock audit logs in the `/snaplock_log` directory under the root of the audit log volume, in subdirectories named `privdel_log` (privileged delete operations) and `system_log` (everything else). Audit log file names contain the timestamp of the first logged operation, making it easy to search for records by the approximate time that operations were executed.

- You can use the `snaplock log file show` command to view the log files on the audit log volume.
- You can use the `snaplock log file archive` command to archive the current log file and create a new one, which is useful in cases where you need to record audit log information in a separate file.

For more information, see the man pages for the commands.

A data protection volume cannot be used as a SnapLock audit log volume.

Steps

1. Create a SnapLock aggregate.

[Create a SnapLock aggregate](#)

2. On the SVM that you want to configure for audit logging, create a SnapLock volume.

[Create a SnapLock volume](#)

3. Configure the SVM for audit logging:

```
snaplock log create -vserver SVM_name -volume snaplock_volume_name -max-file-size size -retention-period default_retention_period
```

The minimum default retention period for audit log files is six months. If the retention period of an affected file is longer than the retention period of the audit log, the retention period of the log inherits the retention period of the file. So, if the retention period for a file deleted using privileged delete is 10 months, and the retention period of the audit log is 8 months, the retention period of the log is extended to 10 months.

The following command configures `SVM1` for audit logging using the SnapLock volume `logVol`. The audit log has a maximum size of 20 GB and is retained for eight months.

```
SVM1::> snaplock log create -vserver SVM1 -volume logVol -max-file-size 20GB -retention-period 8months
```

4. On the SVM that you configured for audit logging, mount the SnapLock volume at the junction path `/snaplock_audit_log`.

[Mount a SnapLock volume](#)

= Use the privileged delete feature

= Create a SnapLock administrator account

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You must have SnapLock administrator privileges to perform a privileged delete. These privileges are defined in the vsadmin-snaplock role. If you have not already been assigned that role, you can ask your cluster administrator to create an SVM administrator account with the SnapLock administrator role.

What you'll need

- You must be a cluster administrator to perform this task.
- You must have logged in on a secure connection (SSH, console, or ZAPI).

Steps

1. Create an SVM administrator account with the SnapLock administrator role:

```
security login create -vserver SVM_name -user-or-group-name  
user_or_group_name -application application -authmethod  
authentication_method -role role -comment comment
```

The following command enables the SVM administrator account SnapLockAdmin with the predefined vsadmin-snaplock role to access SVM1 using a password:

```
cluster1::> security login create -vserver SVM1 -user-or-group-name  
SnapLockAdmin -application ssh -authmethod password -role vsadmin-  
snaplock
```

= Enable the privileged delete feature

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You must explicitly enable the privileged delete feature on the Enterprise volume that contains the WORM files you want to delete.

About this task

The value of the -privileged-delete option determines whether privileged delete is enabled.

Possible values are enabled, disabled, and permanently-disabled.

permanently-disabled is the terminal state. You cannot enable privileged delete on the volume after you set the state to permanently-disabled.

Steps

1. Enable privileged delete for a SnapLock Enterprise volume:

```
volume snaplock modify -vserver SVM_name -volume volume_name -privileged  
-delete disabled|enabled|permanently-disabled
```

The following command enables the privileged delete feature for the Enterprise volume dataVol on SVM1:

```
SVM1::> volume snaplock modify -vserver SVM1 -volume dataVol  
-privileged-delete enabled
```

= Delete WORM files using privileged delete

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use the privileged delete feature to delete Enterprise-mode WORM files during the retention period.

What you'll need

- You must be a SnapLock administrator to perform this task.
- You must have created a SnapLock audit log and enabled the privileged delete feature on the Enterprise volume.

About this task

You cannot use a privileged delete operation to delete an expired WORM file. You can use the `volume file retention show` command to view the retention time of the WORM file that you want to delete. For more information, see the man page for the command.

Step

1. Delete a WORM file on an Enterprise volume:

```
volume file privileged-delete -vserver SVM_name -file file_path
```

The following command deletes the file /vol/dataVol/f1 on the SVM SVM1:

```
SVM1::> volume file privileged-delete -file /vol/dataVol/f1
```

= Use the Legal Hold feature

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

Beginning with ONTAP 9.3, you can use the *Legal Hold* feature to retain Compliance-mode WORM files for the duration of a litigation.

What you'll need

- You must be a SnapLock administrator to perform this task.

[Create a SnapLock administrator account](#)

- You must have logged in on a secure connection (SSH, console, or ZAPI).

About this task

A file under a Legal Hold behaves like a WORM file with an indefinite retention period. It is your responsibility to specify when the Legal Hold period ends.

The number of files you can place under a Legal Hold depends on the space available on the volume.

Steps

1. Start a Legal Hold:

```
snaplock legal-hold begin -litigation-name litigation_name -volume
volume_name -path path_name
```

The following command starts a Legal Hold for all the files in `vol1`:

```
cluster1::>snaplock legal-hold begin -litigation-name litigation1
-volume vol1 -path /
```

2. End a Legal Hold:

```
snaplock legal-hold end -litigation-name litigation_name -volume
volume_name -path path_name
```

The following command ends a Legal Hold for all the files in `vol1`:

```
cluster1::>snaplock legal-hold end -litigation-name litigation1
-volume vol1 -path /
```

= Use the Event Based Retention (EBR) feature

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

Beginning with ONTAP 9.3, you can use the SnapLock *Event Based Retention (EBR)* feature to define how long a file is retained after the occurrence of an event.

What you'll need

- You must be a SnapLock administrator to perform this task.

[Create a SnapLock administrator account](#)

- You must have logged in on a secure connection (SSH, console, or ZAPI).

About this task

The *event retention policy* defines the retention period for the file after the event occurs. The policy can be applied to a single file or all the files in a directory.

- If a file is not a WORM file, it will be committed to the WORM state for the retention period defined in the policy.
- If a file is a WORM file or a WORM appendable file, its retention period will be extended by the retention period defined in the policy.

You can use a Compliance-mode or Enterprise-mode volume.

EBR policies cannot be applied to files under a Legal Hold.

For advanced usage, see [Compliant WORM Storage Using NetApp SnapLock](#).

Using EBR to extend the retention period of already existing WORM files

EBR is convenient when you want to extend the retention period of already existing WORM files. For example, it might be your firm's policy to retain employee W-4 records in unmodified form for three years after the employee changes a withholding election. Another company policy might require that W-4 records be retained for five years after the employee is terminated.

In this situation, you could create an EBR policy with a five-year retention period. After the employee is terminated (the "event"), you would apply the EBR policy to the employee's W-4 record, causing its retention period to be extended. That will usually be easier than extending the retention period manually, particularly when a large number of files is involved.

Steps

1. Create an EBR policy:

```
snapshot event-retention policy create -vserver SVM_name -name policy_name  
-retention-period retention_period
```

The following command creates the EBR policy `employee_exit` on `vs1` with a retention period of ten years:

```
cluster1::>snapshot event-retention policy create -vserver vs1 -name  
employee_exit -retention-period 10years
```

2. Apply an EBR policy:

```
snapshot event-retention apply -vserver SVM_name -name policy_name -volume  
volume_name -path path_name
```

The following command applies the EBR policy `employee_exit` on `vs1` to all the files in the directory `d1`:

```
cluster1::>snapshot event-retention apply -vserver vs1 -name  
employee_exit -volume vol1 -path /d1
```

= Move a SnapLock volume

= Create a SnapLock security administrator account
:icons: font
:relative_path: ./snaplock/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You must have SnapLock security administrator privileges to perform a SnapLock volume move. This privilege is granted to you with the *snaplock* role, introduced in ONTAP 9.8. If you have not already been assigned that role, you can ask your cluster administrator to create a SnapLock security user with this SnapLock security role.

What you'll need

- You must be a cluster administrator to perform this task.
- You must have logged in on a secure connection (SSH, console, or ZAPI).

About this task

The *snaplock* role is associated with the cluster SVM, unlike the *vsadmin-snaplock* role, which is associated with the data SVM.

Step

1. Create an SVM administrator account with the SnapLock administrator role:

```
security login create -vserver SVM_name -user-or-group-name
user_or_group_name -application application -authmethod
authentication_method -role role -comment comment
```

The following command enables the SVM administrator account *SnapLockAdmin* with the predefined *snaplock* role to access SVM2 using a password:

```
cluster1::> security login create -vserver SVM2 -user-or-group-name
SnapLockAdmin -application ssh -authmethod password -role snaplock
```

= Move a SnapLock volume
:icons: font
:relative_path: ./snaplock/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use the `volume move` command to move a SnapLock volume to a destination aggregate.

What you'll need

- You must have created a SnapLock-protected audit log before performing SnapLock volume move.

[Create an audit log.](#)

- If you are using a version of ONTAP earlier than ONTAP 9.10.1, the destination aggregate must be the same SnapLock type as the SnapLock volume you want to move; either Compliance to Compliance or Enterprise to Enterprise. Beginning with ONTAP 9.10.1, this restriction is removed and an aggregate can include both Compliance and Enterprise SnapLock volumes, as well as non-SnapLock volumes.

- You must be a user with the SnapLock security role.

Steps

1. Using a secure connection, log in to the ONTAP cluster management LIF:

```
ssh snaplock_user@node_mgmt_ip
```

2. Move a SnapLock volume:

```
volume move start -vserver SVM_name -volume SnapLock_volume_name  
-destination-aggregate destination_aggregate_name
```

3. Check the status of the volume move operation:

```
volume move show -volume SnapLock_volume_name -vserver SVM_name -fields  
volume,phase,vserver
```

= SnapLock APIs

:icons: font

:relative_path: ./snaplock/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

You can use Zephyr APIs to integrate with SnapLock functionality in scripts or workflow automation. The APIs use XML messaging over HTTP, HTTPS, and Windows DCE/RPC.

-- file-fingerprint-abort

Abort a file fingerprint operation.

-- file-fingerprint-dump

Display file fingerprint information.

-- file-fingerprint-get-iter

Display the status of file fingerprint operations.

-- file-fingerprint-start

Generate a file fingerprint.

-- snaplock-archive-vserver-log

Archive the active audit log file.

-- snaplock-create-vserver-log

Create an audit log configuration for an SVM.

-- snaplock-delete-vserver-log

Delete an audit log configuration for an SVM.

== snaplock-file-privileged-delete

Execute a privileged delete operation.

== snaplock-get-file-retention

Get the retention period of a file.

== snaplock-get-node-compliance-clock

Get the node ComplianceClock date and time.

== snaplock-get-vserver-active-log-files-iter

Display the status of active log files.

== snaplock-get-vserver-log-iter

Display the audit log configuration.

== snaplock-modify-vserver-log

Modify the audit log configuration for an SVM.

== snaplock-set-file-retention

Set the retention time for a file.

== snaplock-set-node-compliance-clock

Set the node ComplianceClock date and time.

== snaplock-volume-set-privileged-delete

Set the privileged-delete option on a SnapLock Enterprise volume.

== volume-get-snaplock-attrs

Get the attributes of a SnapLock volume.

== volume-set-snaplock-attrs

Set the attributes of a SnapLock volume.

= Consistency Groups management

= Consistency groups overview

:icons: font

:relative_path: ./consistency-groups/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

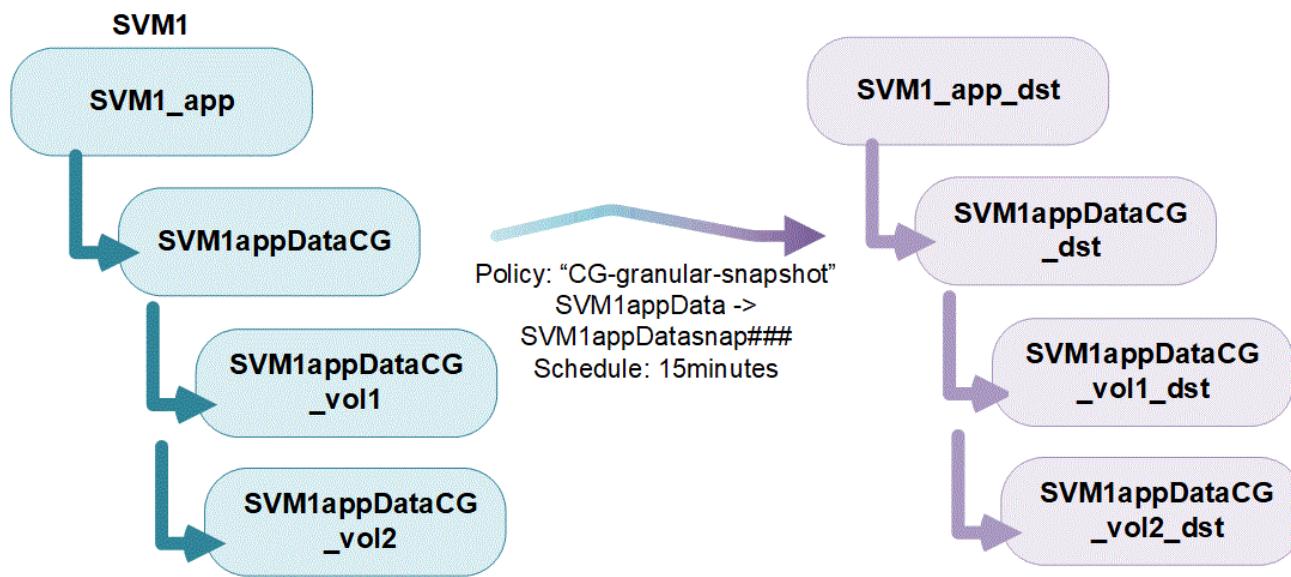

A consistency group is a collection of volumes that provides a write-order consistency guarantee for an application workload spanning multiple volumes.

Consistency groups facilitate application workload management, providing easy management of local and remote protection policies and providing simultaneous crash-consistent or application-consistent

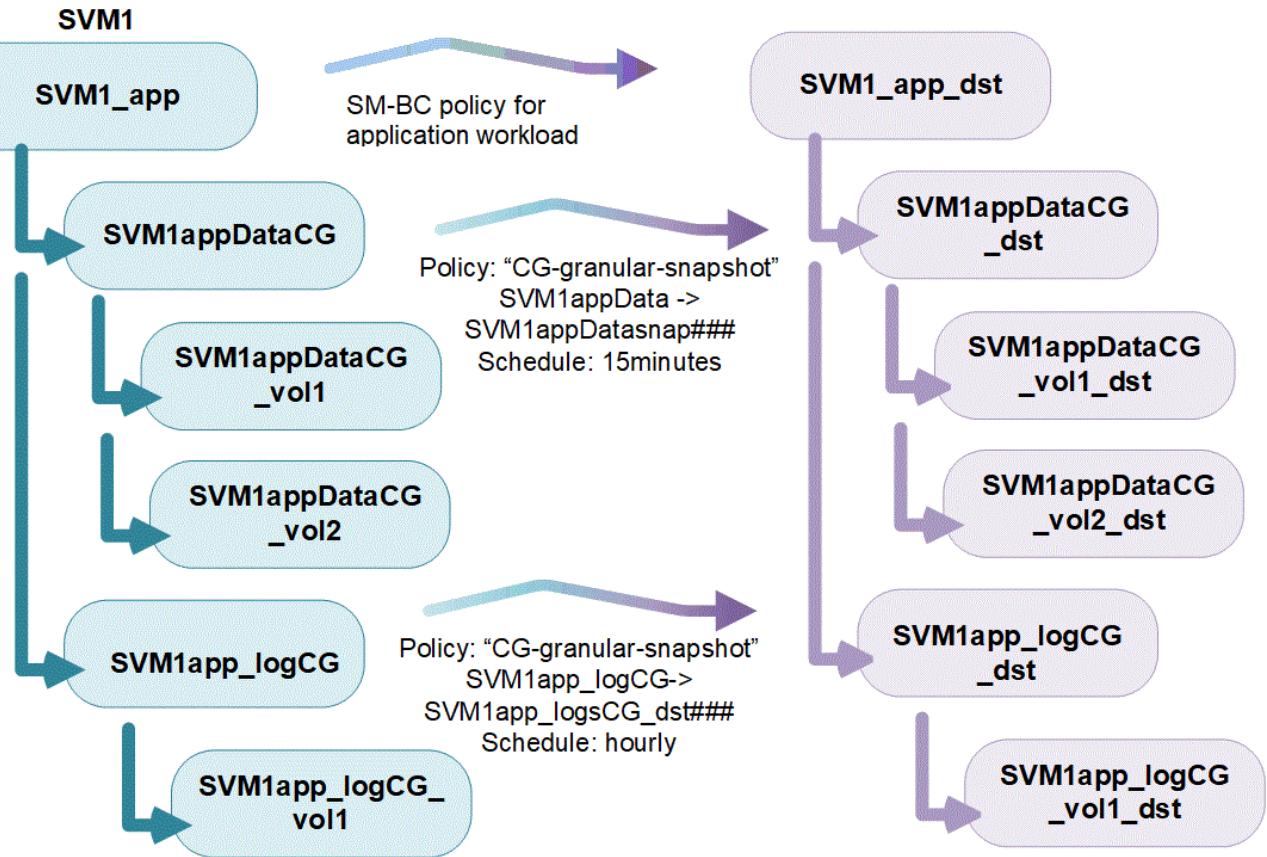

Snapshot copies of a collection of volumes at a point in time. Snapshots in consistency groups enable an entire application workload to be restored.

Consistency groups support any FlexVol volume regardless of protocol (NAS, SAN, or NVMe) and can be managed through the ONTAP REST APIs or in System Manager under the **Storage > Consistency Groups** menu item.

Consistency groups can exist on their own or in a hierarchical relationship. An individual consistency group is a collection of volumes. Volumes can have individual local Snapshot policies in addition to inherited Snapshot policies from a consistency group. The consistency group can only have one SM-BC relationship and shared SM-BC policy, which can be used to recover the entire consistency group.

Larger application workloads might require multiple consistency groups. In these situations, multiple consistency groups can be placed together in a hierarchical relationship. In this configuration, single consistency groups become the child components of a parent consistency group. The parent consistency group can include up to five child consistency groups. Like in individual consistency groups, a remote SM-BC protection policy can be applied to the entire configuration of consistency groups (parent and children) to recover the application workload.

== Protection

Consistency groups offer remote protection through SnapMirror Business Continuity (SM-BC) and local protection through Snapshot policies. In order to utilize remote protection, you must meet the requirements for [SnapMirror Business Continuity deployments](#). By default, consistency groups do not have a protection policy set and will not protect your data unless a policy is selected. See [“Protect a consistency group”](#) for more information.

== Upgrade considerations

Consistency groups created with SM-BC in ONTAP 9.8 and 9.9.1 will automatically be upgraded and become manageable under **Storage > Consistency Groups** in System Manager or the ONTAP REST API when upgrading to ONTAP 9.10.1. For more information about upgrading, see [SM-BC upgrade and revert considerations](#).

Consistency group snapshots created with the ONTAP REST API can be managed through System Manager’s Consistency Group interface and through consistency group API endpoints.

Snapshots created with the ONTAPI commands `cg-start` and `cg-commit` will not be recognized as consistency group Snapshots and thus cannot be managed through System Manager’s Consistency Group interface or the consistency group endpoints in the ONTAP API.

== Consistency group object limits

Consistency Groups	Scope	Minimum	Maximum
Number of consistency groups	Cluster	0	Same as maximum volume count in cluster

Number of parent consistency groups	Cluster	0	Same as maximum volume count in cluster
Number of individual and parent consistency groups	Cluster	0	Same as maximum volume count in cluster
Consistency group	Same as maximum volume count in cluster	1	80
Number of volumes in the child of a parent consistency group	Parent consistency group	1	80
Number of volumes in a child consistency group	Child consistency group	1	80
Number of child consistency groups in a parent consistency group	Parent consistency group	1	5

If you are using SM-BC, refer to [SM-BC restrictions and limitations for limits](#).

= Configure a single consistency group

:icons: font

:relative_path: ./consistency-groups/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest//media/

Consistency groups can be created with existing volumes or with new volumes. Once a volume is added to a consistency group, it cannot be added to another consistency group. A volume can be removed from a consistency group by deleting the volume or deleting the consistency group.

== Create a consistency group with new volumes

Steps

1. Select **Storage > Consistency groups**.
2. Select **+Add**. then **Using New LUNs**.
3. Name the consistency group. Designate the number of LUNs and capacity per LUN.
4. Select the host operating system and LUN format. Enter the host initiator information.
5. To configure protection policies, add a child consistency group, or show more options about host initiators, select **More options**
6. Select **Save**.
7. Confirm your consistency group has been created by returning to the main consistency group menu where it will appear once the ONTAP job completes. If you set a protection policy, look under the appropriate policy, remote or local, which should display a green shield with a checkmark.

== Create a consistency group with existing volumes

.Steps

- . Select **Storage > Consistency groups**.
- . Select **+Add**. then **Using existing volumes**.
- . Name the consistency group and select the storage VM.

- . Select the existing volumes to include. Only volumes that are not already part of a consistency group will be available for selection.

+

If creating a consistency group with new volumes, the consistency group supports FlexVol volumes. Volumes with Asynchronous or Synchronous SnapMirror relationships can be added to consistency groups, but they are not consistency group-aware. Consistency groups do not support S3 buckets, MCC, or SVMs with SVMDR relationships.

+

. Select **Save**.

- . Confirm your consistency group has been created by returning to the main consistency group menu where it will appear once the ONTAP job completes. If you have chosen a protection policy, confirm it was properly set by selecting your consistency group from the menu. If you set a protection policy, look under the appropriate policy, remote or local, which should display a green shield with a checkmark.

= Configure a hierarchical consistency group

:icons: font

:relative_path: ./consistency-groups/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

If your application workload consists of more than one subset of volumes, where each subset is consistent across its own associated volumes, ONTAP allows you to create a hierarchical consistency group. Hierarchical consistency groups have a parent that can include up to five individual consistency groups. Hierarchical consistency groups can support different local Snapshot policies across consistency groups or individual volumes. If you use a remote SM-BC policy, that will apply for the entire consistency group.

For object limits on consistency groups, see [Object limits for consistency groups](#).

== Create a hierarchical consistency group with new volumes

Steps

1. Select **Storage > Consistency groups**.
2. Select **+Add**, then **Using New LUNs**.
3. Name the consistency group. Designate the number of LUNs and capacity per LUN.
4. Select the host operating system and LUN format. Enter the host initiator information.
5. To configure protection policies, add a child consistency group, or show more options about host initiators, select **More options**.
6. To add a child consistency group, select **+Add child consistency group**.
7. Select the performance level, the number of LUNs, and capacity per LUN. Designate the host operating system, LUN format, and select a new or existing host initiator group.
8. **Optional:** select a local snapshot policy.
9. Repeat for up to five child consistency groups.
10. Select **Save**.
11. Confirm your consistency group has been created by returning to the main consistency group menu

where it will appear once the ONTAP job completes. If you set a protection policy, look under the appropriate policy, remote or local, which should display a green shield with a checkmark in it.

== Create a hierarchical consistency group with existing volumes

.Steps

- . Select **Storage > Consistency groups**.
- . Select **+Add**, then **Using existing volumes**.

. Select the storage VM.

. Select the existing volumes to include. Only volumes that are not already part of a consistency group will be available for selection.

. To add a child consistency group, select **+Add Child Consistency Group**. Create the necessary consistency groups, which will be named automatically.

. Assign existing volumes to each consistency group.

. **Optional:** select a local Snapshot policy.

. Repeat for up to five child consistency groups.

. Select **Save**.

. Confirm your consistency group has been created by returning to the main consistency group menu where it will appear once the ONTAP job completes. If you have chosen a protection policy, confirm it was properly set by selecting your consistency group from the menu. If you set a protection policy, look under the appropriate policy, remote or local, which should display a green shield with a checkmark in it.

= Protect a consistency group

:icons: font

:relative_path: ./consistency-groups/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Consistency groups offer easily managed local and remote protection for SAN, NAS, and NVMe applications that span multiple volumes.

Creating a consistency group does not automatically enable protection. Local and/or remote protection policies can be set at the time of creation or after creating your consistency group. Protection policies can include local Snapshot copies or remote SnapMirror protection with SnapMirror Business Continuity (SM-BC). If you are utilizing nested consistency groups, you can set different protection policies for individual volumes.

If you are utilizing remote SM-BC protection, to ensure Snapshot copies of consistency groups created on your consistency group are copied to the destination, the policy labels in the source and destination cluster must match. SM-BC will not replicate Snapshot copies by default unless a rule with a SnapMirror label is added to the predefined AutomatedFailOver policy and the Snapshot copies are created with that label. To learn more about this process, refer to [Configure protection for business continuity](#).

Recovery can occur for an entire consistency group, a single consistency group in a hierarchical configuration, or for individual volumes within the consistency group. Recovery can be achieved by selecting the consistency group you want to recover from, selecting the Snapshot copy type, and then identifying the particular Snapshot copy to base the restoration on. For more information about this process, see [Restore a volume from an earlier Snapshot copy](#).

Beginning with ONTAP 9.10.1, System Manager visualizes LUN maps under the **Protection > Relationships** menu. When you select a source relationship, System Manager displays a visualization of the source relationships. By selecting a volume, you can delve deeper into these relationships to see a list of the contained LUNs and the initiator group relationships. This information can be downloaded as an Excel workbook from the individual volume view. The task will run in the background.

== Set a local Snapshot protection policy

Steps

1. Select the consistency group you have created from the Consistency group menu.
2. At the top right of the overview page for the consistency group, select **Edit**.
3. Check the box next to **Schedule Snapshot copies (local)**.
4. Select a Snapshot policy. To configure a new, custom policy, refer to [Create a custom data protection policy](#).
5. Select **Save**.
6. Return to the consistency group overview menu. In the left column under **Snapshot Copies (Local)**, the status should say protected next to .

== Set a remote SM-BC policy

Steps

1. Ensure you have met the prerequisites for using SM-BC. See [SM-BC prerequisites](#)

SM-BC relationships cannot be established on volumes mounted for NAS access.

2. Select the consistency group you have created from the Consistency group menu.
3. At the top right of the overview page, select **More** then **Protect**.
4. The source-side information should be autofilled on the left-hand side of the page.
5. Select the appropriate cluster and storage VM for the destination. Select a protection policy. Ensure that **Initialize relationship** is checked.
6. Click **Save**.
7. The consistency group will have to initialize and synchronize. When this is complete, under **SnapMirror (Remote)** the status should say "Protected" next to .

Next Steps +

[Configure Snapshot copies](#)

[Create custom data protection policies](#)

[Recover from Snapshot copies](#)

[Restore a volume from an earlier Snapshot copy](#)

= Delete a consistency group

:icons: font

:relative_path: ./consistency-groups/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

If you decide that you no longer need a consistency group, it can be deleted.

Deleting a consistency group deletes the instance of the consistency group and does **not** impact the constituent volumes or LUNs. Deleting a consistency group does not result in deletion of the Snapshots present on each volume, but they will no longer be accessible as consistency group Snapshots. They can, however, continue to be managed as ordinary volume granular snapshots.

Consistency groups will also be deleted if all of the volumes in a consistency group are deleted. Volumes can only be removed from a consistency group if the volume itself is deleted, in which case the volume is automatically removed from the consistency group.

Steps

1. In the consistency group menu under **Storage > Consistency groups**, select the consistency group you would like to delete.
2. Next to the name of the consistency group, select  and then **Delete**.

= SnapMirror Business Continuity

= Overview

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..../media/

Beginning with ONTAP 9.8, you can use SnapMirror Business Continuity (SM-BC) to protect applications with LUNs, enabling applications to fail over transparently, ensuring business continuity in case of a disaster. SM-BC is supported on AFF clusters or All SAN Array (ASA) clusters, where the primary and secondary clusters can be either AFF or ASA. SM-BC protects applications with iSCSI or FCP LUNs.

== Benefits

SnapMirror Business Continuity provides the following benefits:

- Provides continuous availability for business-critical applications
- Ability to host critical applications alternately from primary and secondary site
- Simplified application management using consistency groups for dependent write-order consistency
- The ability to test failover for each application
- Instantaneous creation of mirror clones without impacting application availability

== Typical use cases

Application deployment for zero RTO or Transparent Application Failover

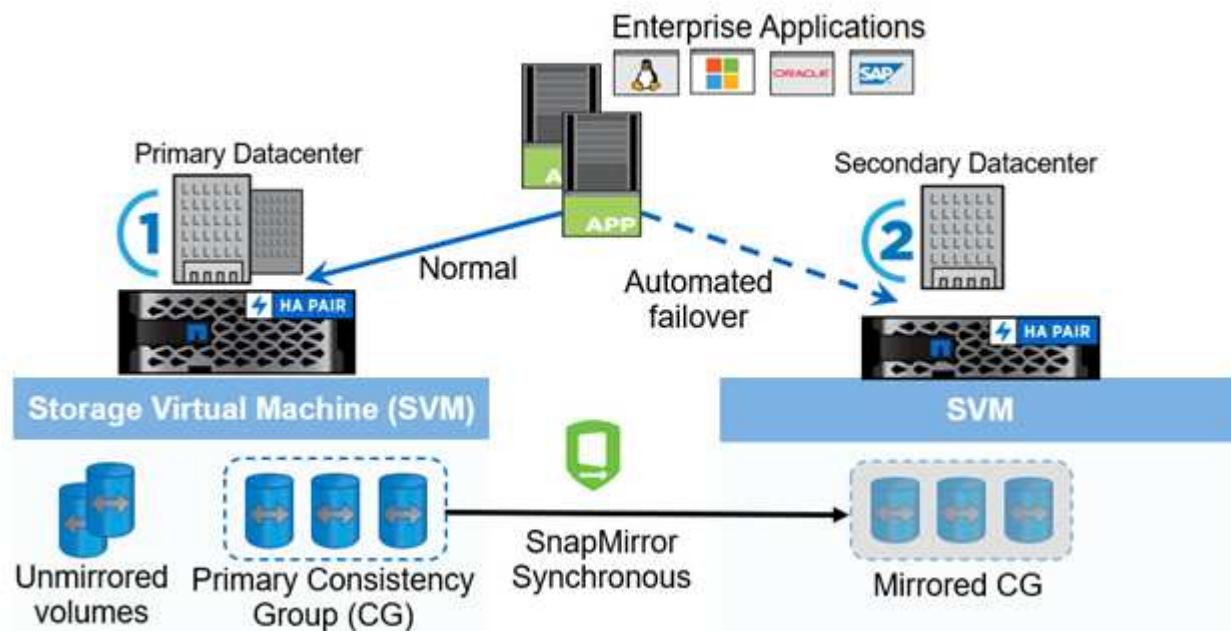

Transparent Application Failover is based on host multipath I/O (MPIO) software-based path failover to achieve non-disruptive access to the storage. Both LUN copies, for example, primary(L1P) and mirror copy(L1S), have the same identity (serial number) and are reported as read-writable to the host. However, reads and writes are serviced only by the primary volume. I/Os issued to the mirror copy are proxied to the primary copy. The host's preferred path to L1 is VS1:N1 based on Asymmetric Logical Unit Access (ALUA) access state Active Optimized (A/O). Mediator is recommended as part of the deployment, primarily to perform failover in case of a storage outage on the primary.

Disaster scenario

The site hosting the primary cluster experiences a disaster. Host multipathing software marks all paths through the cluster as down and uses paths from the secondary cluster. The result is a non-disruptive failover to the mirror copy for LUN L1. L1S is converted from a mirror copy to an active copy of LUN L1. The failover happens automatically when an external Mediator is configured. The host's preferred path to L1 becomes VS2:N1.

== Architecture

The following figure illustrates the operation of the SnapMirror Business Continuity feature at a high level.

==== Additional information

For more information about data protection using SnapMirror Synchronous, see the [SnapMirror Synchronous disaster recovery documentation](#).

= Key concepts

:hardbreaks:

:icons: font

:linkatrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

As you begin to explore the ONTAP SnapMirror Business Continuity and plan a deployment, it is helpful to become familiar with the key terminology and concepts.

SM-BC

Acronym for the SnapMirror Business Continuity (SM-BC) solution available with ONTAP 9.8 and later.

Consistency group

Beginning with ONTAP 9.10.1, consistency groups have become a first order management unit. To learn more about consistency groups, refer to [Consistency groups overview](#).

A consistency group (CG) is a collection of FlexVol volumes that provide a write order consistency guarantee for the application workload which needs to be protected for business continuity. The purpose of a consistency group is to take simultaneous crash-consistent Snapshot copies of a collection of volumes at a point in time. In regular deployment, the group of volumes picked to be part of a CG are mapped to an application instance. SnapMirror relationships, also known as a CG relationship, is established between a source CG and a destination CG. The source and destination CGs must contain the same number and type of volumes.

Constituent

The individual FlexVol volumes that are part of a consistency group.

Mediator

ONTAP Mediator provides an alternate health path to the peer cluster, with the intercluster LIFs providing the other health path. With the Mediator's health information, clusters can differentiate between intercluster LIF failure and site failure. When the site goes down, Mediator passes on the health information to the peer cluster on demand, facilitating the peer cluster to fail over. With the Mediator-provided information and the intercluster LIF health check information, ONTAP determines whether to perform an auto failover, if it is failover incapable, continue or stop.

Mediator is one of three parties in the SM-BC quorum, working with the primary cluster and the secondary cluster to reach a consensus. A consensus requires at least two parties in the quorum to agree to an operation.

Out of Sync (OOS)

The application I/O is not replicating to the secondary storage system. The destination volume is not in sync with the source volume because SnapMirror replication is not occurring. If the mirror state is Snapmirrored, this indicates a transfer failure or failure due to an unsupported operation.

Zero RPO

Zero recovery point objective. This is the acceptable amount of data loss from downtime.

Zero RTO

Zero recovery time objective or Transparent Application Failover is achieved by using host multipath I/O (MPIO) software-based path failover to provide non-disruptive access to the storage.

Planned failover

A manual operation to change the roles of copies in a SM-BC relationship. The primary becomes the secondary and the secondary becomes the primary. ALUA reporting also changes.

Automatic unplanned failover (AUFO)

An automatic operation to perform a failover to the mirror copy. The operation requires assistance from Mediator to detect that the primary copy is unavailable.

= Planning

= Prerequisites

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

There are several prerequisites that you should consider as part of planning a SnapMirror Business Continuity solution deployment.

==== Hardware

- Only two-node HA clusters are supported
- Both clusters must be either AFF or ASA (no mixing)

==== Software

* ONTAP 9.8 or later

* ONTAP Mediator 1.2 or later

* A Linux server or virtual machine for the ONTAP Mediator running one of the following:

Mediator version	Supported Linux versions
1.3	Red Hat Enterprise Linux: 7.6, 7.7, 7.8, 7.9, 8.0, 8.1, 8.2, 8.3 CentOS: 7.6, 7.7, 7.8, 7.9
1.2	Red Hat Enterprise Linux: 7.6, 7.7, 7.8, 8.0, 8.1 CentOS: 7.6, 7.7, 7.8

==== Licensing

- SnapMirror synchronous (SM-S) license must be applied on both clusters
- SnapMirror license must be applied on both clusters

If your ONTAP storage systems were purchased before June 2019, click [NetApp ONTAP Master License Keys](#) to get the required SM-S license.

==== Networking environment

- Inter-cluster latency round trip time (RTT) must be less than 10 milliseconds

==== Supported protocols

- Only SAN protocols are supported (not NFS/CIFS)
- Only Fibre Channel and iSCSI protocols are supported
- The default IPspace is required by SM-BC for cluster peer relationships. Custom IPspace is not supported.

==== ONTAP Mediator

- Must be provisioned externally and attached to ONTAP for transparent application failover.
- For more information about the ONTAP Mediator, see [Installing or upgrading the ONTAP Mediator service](#).

==== Read-write destination volumes

- SM-BC relationships are not supported on read-write destination volumes. Before you can use a read-write volume, you must convert it to a DP volume by creating a volume-level SnapMirror relationship and then deleting the relationship. For details, see [Converting existing relationships to SM-BC relationships](#)

==== Large LUNs and large volumes

- Large LUNs and large volumes greater than 100TB are supported only on All SAN Arrays

You must ensure that both the primary and secondary cluster are All SAN Arrays, and that they both have ONTAP 9.8 installed. If the secondary cluster is running a version earlier than ONTAP 9.8 or if it is not an All SAN Array, the synchronous relationship can go out of sync if the primary volume grows larger than 100 TB.

= Additional restrictions and limitations

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

There are several additional restrictions and limitations when using the SnapMirror Business Continuity solution.

==== Consistency groups

From ONTAP 9.8 to 9.9.1, the maximum number of SM-BC consistency group relationships in a cluster is five, a limit which is platform-independent. Beginning with ONTAP 9.10.1, the maximum number of SM-BC consistency group relationships in a cluster is 20.

==== Volumes per consistency group

From ONTAP 9.8 to 9.9.1, the maximum number of volumes supported per SM-BC consistency group relationship is twelve, a limit which is platform-independent. Beginning with ONTAP 9.10.1, the maximum number of volumes supported per SM-BC relationship is sixteen.

==== Volumes

Limits in SM-BC are calculated based on the number of endpoints, not the number of relationships. A consistency group with 12 volumes contributes 12 endpoints on both the source and destination. Both SM-BC and SnapMirror Synchronous relationships contribute to the total number of endpoints.

The maximum endpoints per platform are included in the following table.

S. No	Platform	Endpoints per HA for SM-BC		Overall sync and SM-BC endpoints per HA	
		ONTAP 9.8-9.9.1	ONTAP 9.10.1	ONTAP 9.8-9.9.1	ONTAP 9.10.1
1	AFF	60	200	80	200
2	ASA	60	200	80	200

==== SAN object limits

The following SAN object limits are included in the following table and apply regardless of the platform.

Limits of objects in an SM-BC relationship	Count
LUNs per volume	256
LUN maps per node	2048

Limits of objects in an SM-BC relationship	Count
LUN maps per cluster	4096
LIFs per VServer (with at least one volume in an SM-BC relationship)	256
Inter-cluster LIFs per node	4
Inter-cluster LIFs per cluster	8

==== NTFS Security Style

NTFS security style is not supported on SM-BC volumes.

==== Solaris Host setting recommendation for SM-BC configuration

Beginning with ONTAP 9.10.1, SM-BC supports Solaris 11.4. In order to ensure the Solaris client applications are non-disruptive when an unplanned site failover switchover occurs in an SM-BC environment, the following setting needs to be configured on Solaris 11.4 host. This setting will override the failover module `f_tpgs` in order to prevent the code path that detects the contradiction from being executed.

Follow the instructions to configure the override parameter:

1. Create configuration file `/etc/driver/drv/scsi_vhci.conf` with an entry similar to the following for the NetApp storage type connected to the host:

```
scsi-vhci-failover-override =
"NETAPP LUN", "f_tpgs"
```

2. Use `devprop` and `mdb` commands to verify the override has been successfully applied:

```
root@host-A:~# devprop -v -n /scsi_vhci scsi-vhci-failover-override
scsi-vhci-failover-override=NETAPP LUN + f_tpgs
root@host-A:~# echo "*scsi_vhci_dip::print -x struct dev_info
devi_child | ::list struct dev_info devi_sibling| ::print struct
dev_info devi_mdi_client| ::print mdi_client_t ct_vprivate| ::print
struct scsi_vhci_lun svl_lun_wwn svl_fops_name" | mdb -k`
```

```
svl_lun_wwn = 0xa002a1c8960 "600a098038313477543f524539787938"
svl_fops_name = 0xa00298d69e0 "conf f_tpgs"
```

 `conf` will be added to the `svl_fops_name` when a `scsi-vhci-failover-override` has been applied.

For additional information and recommended changes to default settings, refer to NetApp KB article [Solaris Host support recommended settings in SnapMirror Business Continuity \(SM-BC\) configuration](#).

```
= ONTAP access options
:hardbreaks:
:icons: font
:linkatrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

You have several access options available when configuring the ONTAP nodes participating in an SM- BC deployment. You should select the option that best matches your specific environment and deployment goals.

In all cases, you must sign in using the administrator account with a valid password.

Command line interface

The text-based command line interface is available through the ONTAP management shell. You can access the CLI using secure shell (SSH).

System Manager

You can connect to the System Manager using a modern web browser. The web GUI provides an intuitive and easy-to-use interface when accessing the SnapMirror Business Continuity functionality. For more information about using System Manager, see [System Manager documentation](#).

REST API

The ONTAP REST API exposed to external clients provides another option when connecting to the ONTAP. You can access the API using any mainstream programming language or tool that supports REST web services. Popular choices include:

- Python (including the ONTAP Python client library)
- Java
- Curl

Using a programming or scripting language provides an opportunity to automate the deployment and management of a SnapMirror Business Continuity deployment. For more information, see the ONTAP online documentation page at your ONTAP storage system.

```
= Prepare to use the ONTAP CLI
```

```
:hardbreaks:
:icons: font
:linkatrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

You should be familiar with the following commands when deploying the SnapMirror Business Continuity solution using the ONTAP command line interface.

SM-BC does not support the snapmirror quiesce and snapmirror resume commands for relationships with active sync policy.

For more information about the following ONTAP commands, see [NetApp Documentation: ONTAP 9](#).

Command	Description
lun igrup create	Create an igrup on a cluster
lun map	Map a LUN to an igrup
lun show	Display a list of LUNs
snapmirror create	Create a new SnapMirror relationship
snapmirror initialize	Initialize an SM-BC consistency group
snapmirror update	Initiates a common snapshot creation operation
snapmirror show	Display a list of SnapMirror relationships
snapmirror failover	Start a planned failover operation
snapmirror resync	Start a resynchronization operation
snapmirror delete	Delete a SnapMirror relationship
snapmirror release	Remove source information for a SnapMirror relationship

= Prepare to use the ONTAP Mediator

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

The ONTAP Mediator establishes a quorum for the ONTAP clusters in an SM-BC relationship. It coordinates automated failover when a failure is detected and helps to avoid split-brain scenarios when each cluster simultaneously tries to establish control as the primary cluster.

== Prerequisites for the ONTAP Mediator

The ONTAP Mediator includes its own set of prerequisites. You must meet these prerequisites before installing the mediator. For more information, see [Installing or upgrading the ONTAP Mediator service](#).

== Network configuration

By default, the ONTAP Mediator provides service through TCP port 31784. You should make sure that port 31784 is open and available between the ONTAP clusters and the mediator.

= Summary of deployment best practices

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

There are several best practices that you should consider as part of planning an SnapMirror Business Continuity deployment.

== SAN

The SnapMirror Business Continuity solution supports only SAN workloads. You should follow the SAN best practices in all cases.

In addition:

- Replicated LUNs in the secondary cluster must be mapped to the host and the I/O paths to the LUNs from both the primary and secondary cluster must be discovered at the time of host configuration.
- After an out of sync (OOS) event exceeds 80 seconds, or after an automatic unplanned failover, it is important to rescan the host LUN I/O path to ensure that there is no I/O path loss. For more information, see the respective host OS vendor's documentation on rescan of LUN I/O paths.

== Mediator

To be fully functional and to enable automatic unplanned failover, the external ONTAP mediator should be provisioned and configured with ONTAP clusters.

When installing the mediator, you should replace the self-signed certificate with a valid certificate signed by a mainstream reliable CA.

== SnapMirror

You should terminate an SnapMirror relationship in the following order:

1. Perform `snapmirror delete` at the destination cluster
2. Perform `snapmirror release` at the source cluster

= Manage SnapMirror for Business Continuity using System Manager

= Configure Mediator

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

Use System Manager to configure the Mediator server to be used for automated failover. You can also replace the self-signed SSL and CA with the third party validated SSL Certificate and CA if you have not already done so.

Steps

1. Navigate to **Protection > Overview > Mediator > Configure**.
2. Click **Add**, and enter the following Mediator server information:
 - IPv4 address
 - Username
 - Password
 - Certificate

= Configure protection for business continuity
:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

Configuring protection for business continuity involves selecting LUNs on the ONTAP source cluster and adding them to a consistency group. Open System Manager from a browser on the source cluster to begin configuring protection for business continuity.

This workflow is designed for ONTAP 9.8 and 9.9. Beginning with ONTAP 9.10.1, it is recommended that you begin by creating a consistency group and then use SM-BC as a remote protection.

== About this task

- LUNs must reside on the same storage VM.
- LUNs can reside on different volumes.
- The source and destination cluster cannot be the same.
- The default IPspace is required by SM-BC for cluster peer relationships. Custom IPspace is not supported.

Steps

1. Choose the LUNs you want to protect and add them to a protection group: **Protection > Overview > Protect for Business Continuity > Protect LUNs**.
2. Select one or more LUNs to protect on the source cluster.
3. Select the destination cluster and SVM.
4. **Initialize relationship** is selected by default. Click **Save** to begin protection.
5. Go to **Dashboard > Performance** to verify IOPS activity for the LUNs.
6. On the destination cluster, use System Manager to verify that the protection for business continuity relationship is in sync: **Protection > Relationships**.

= Reestablish the original protection relationship after an unplanned failover

:toc: macro
:toclevels: 1
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

ONTAP uses the ONTAP Mediator to detect when a failure occurs on the primary storage system and executes automatic unplanned failover to the secondary storage system. You can use System Manager to reverse the relationship and reestablish the original protection relationship when original source cluster is back online.

Steps

1. Navigate to **Protection > Relationships** and wait for the relationship state to show “InSync.”
2. To resume operations on the original source cluster, click  and select **Failover**.

= Installation and setup using the ONTAP CLI

= High level deployment workflow

:hardbreaks:

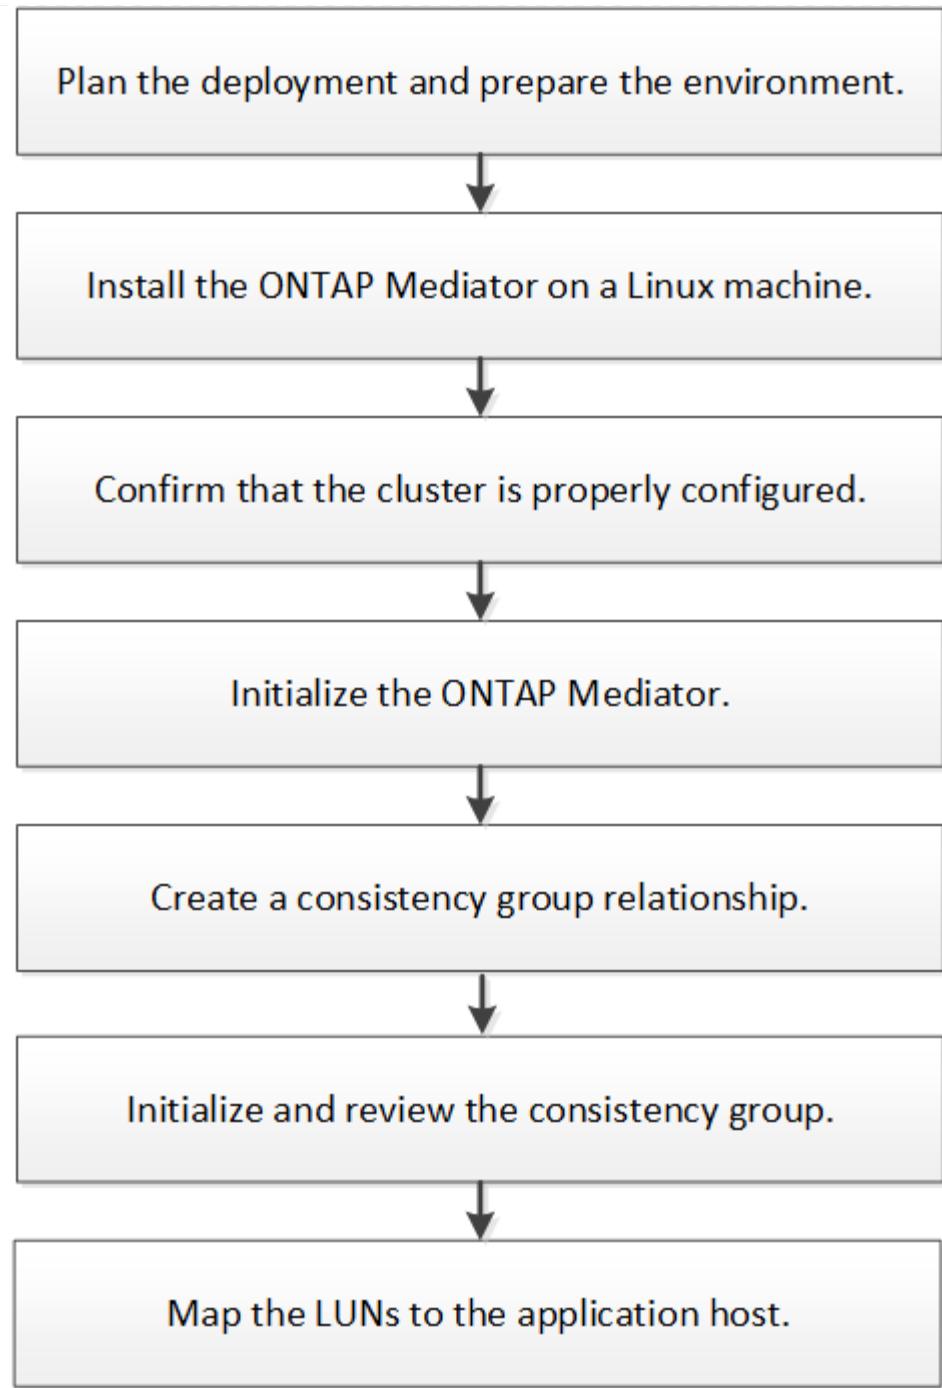

:icons: font

:linkatrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use the following workflow to install and implement the SnapMirror Business Continuity solution.

```
= Install the ONTAP Mediator  
:hardbreaks:  
:icons: font  
:linkatrs:  
:relative_path: ./smbc/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

You must install the ONTAP Mediator, which includes accepting the licensing agreement, before you can configure and use the SnapMirror Business Continuity solution.

Before you begin

The following software is required:

- ONTAP Mediator 1.2 or later
- One of the following Linux distributions:

Mediator version	Supported Linux versions
1.3	Red Hat Enterprise Linux: 7.6, 7.7, 7.8, 7.9, 8.0, 8.1, 8.2, 8.3 CentOS: 7.6, 7.7, 7.8, 7.9
1.2	Red Hat Enterprise Linux: 7.6, 7.7, 7.8, 8.0, 8.1 CentOS: 7.6, 7.7, 7.8

About this task

You should install the ONTAP Mediator at an external site that is physically separated from the two ONTAP clusters.

For complete installation instructions, see [Installing or upgrading the ONTAP Mediator service](#)

Steps

1. Sign into the Linux system that will host the ONTAP Mediator.
2. Download the mediator installation package from the ONTAP Mediator page.
[ONTAP Mediator download page](#).
3. Install the ONTAP Mediator and respond to all prompts as required:

```
./ontap-mediator_1.3
```
4. Optionally replace the self-signed SSL and certificate authority (CA) with the third party validated SSL Certificate and CA. The certificate you install must not be expired. Copy the contents of the ca.crt file from the ONTAP Mediator directory:

```
/opt/netapp/lib/ontap_mediator/ontap_mediator/server_config
```

5. At the ONTAP CLI, install the certificate on both the local and peer cluster:

```
security certificate install -type server-ca -vserver cserverName
```

= Confirm the ONTAP cluster configuration
:hardbreaks:
:icons: font
:linkatrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You should make sure that your source and destination clusters are configured properly.

About this task

Proceed through each of the following steps. For each step, you should confirm that the specific configuration has been performed. Use the link included after each step to get more information as needed.

Steps

1. Confirm that a cluster peering relationship exists between the clusters.

The default IPspace is required by SM-BC for cluster peer relationships. Custom IPspace is not supported.

[Configure peer relationships](#)

2. Confirm that the Storage VMs are created on each cluster.

[Creating an SVM](#)

3. Confirm that a peer relationship exists between the Storage VMs on each cluster.

[Creating an SVM peering relationship](#)

4. Confirm that the volumes exist for your LUNs.

[Creating a volume](#)

5. Confirm that at least one SAN LIF is created on each node in the cluster.

[Considerations for LIFs in a cluster SAN environment](#)

[Creating a LIF](#)

6. Confirm that the necessary LUNs are created and mapped to igroup, which is used to map LUNs to the initiator on the application host.

[Create LUNs and map igroups](#)

7. Rescan the application host to discover any new LUNs.

= Initialize the ONTAP Mediator

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You must initialize Mediator on one of your cluster peers before SM-BC can perform planned and automatic unplanned failover operations.

About this task

You can initialize Mediator from either cluster. When you issue the `mediator add` command on one cluster, Mediator is automatically added on the other cluster.

Steps

1. Initialize Mediator on one of the clusters:

```
snapmirror mediator add -mediator-address IP_Address -peer-cluster  
cluster_name -username user_name
```

Example

```
cluster1::> snapmirror mediator add -mediator-address 192.168.10.1  
-peer-cluster cluster2 -username mediatoradmin  
Notice: Enter the mediator password.  
  
Enter the password: *****  
Enter the password again: *****
```

2. Check the status of the Mediator configuration:

```
snapmirror mediator show
```

Mediator Address	Peer Cluster	Connection Status	Quorum Status
192.168.10.1	cluster-2	connected	true

-quorum-status indicates whether the SnapMirror consistency group relationships are synchronized with Mediator.

= Create a consistency group relationship

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You must create a SM-BC consistency group which also establishes the synchronous consistency group relationship.

This workflow applies to users in ONTAP 9.8 and 9.9.1. If using these ONTAP CLI commands beginning with ONTAP 9.10.1, they will still work to create a consistency group, however, it is recommended that you manage consistency groups with System Manager or the ONTAP REST API.

Before you begin

The following prerequisites and restrictions apply:

- You must be a cluster or storage VM administrator
- You must have a SnapMirror Synchronous license
- The destination volumes must be type DP

- The primary and the secondary storage VM must be in a peered relationship
- All constituent volumes in a consistency group must be in a single Storage VM
- You cannot establish SM-BC consistency group relationships across ASA clusters and non-ASA clusters
- The name of the consistency group must be unique

About this task

You must create the consistency group relationship from the destination cluster. You can map up to 12 constituents using the `cg-item-mappings` parameter on the `snapmirror create` command.

Steps

1. Create a consistency group and constituent relationship. This example creates two consistency groups: `cg_src` with constituent volumes `vol1` and `vol2`, and `cg_dist` with constituent volumes `vol1_dr` and `vol2_dr`.

```
destination::> snapmirror create -source-path vs1_src:/cg/cg_src
-destination-path vs1_dst:/cg/cg_dst -cg-item-mappings
vol_src1:@vol_dst1,vol_src2:@vol_dst2 -policy AutomatedFailOver
```

= Initialize a consistency group

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

After creating a consistency group, you must initialize it.

This workflow applies to users in ONTAP 9.8 and 9.9.1. If using these ONTAP CLI commands beginning with ONTAP 9.10.1, they will still work to initialize a consistency group, however, it is recommended that you manage consistency groups with System Manager or the ONTAP REST API.

Before you begin

You must be a cluster or storage VM administrator.

About this task

You initialize the consistency group from the destination cluster.

Steps

1. Sign in to the ONTAP CLI at the destination cluster and initialize the consistency group:

```
destination::>snapmirror initialize -destination-path vs1_dst:/cg/cg_dst
```

2. Confirm that the initialization operation completed successfully. The status should be `InSync`.

```
snapmirror show
```

= Mapping LUNs to the application hosts

:hardbreaks:

```
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/
```

You must create an igroup on each cluster so you can map LUNs to the initiator on the application host.

About this task

You should perform this configuration on both the source and destination clusters.

Steps

1. Create an igroup on each cluster:

```
lun igrup create -igroup name -protocol fcp|iscsi -ostype os -initiator
initiator_name
```

Example

```
lun igrup create -igroup ig1 -protocol iscsi -ostype linux
-initiator -initiator iqn.2001-04.com.example:abc123
```

2. Map LUNs to the igroup:

```
lun map -path path_name -igroup igrup_name
```

Example:

```
lun map -path /vol/src1/11 -group ig1
```

3. Verify the LUNs are mapped:

```
lun show
```

4. On the application host, discover the new LUNs.

= Administration

= Create a common Snapshot copy

```
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/
```

In addition to the regularly scheduled Snapshot copy operations, you can manually create a common Snapshot copy between the volumes in the primary SnapMirror consistency group and the volumes in the secondary SnapMirror consistency group.

In ONTAP 9.8, the scheduled snapshot creation interval is one hour. Beginning with ONTAP 9.9.1, that interval is 12 hours.

Before you begin

The SnapMirror group relationship must be in sync.

Steps

1. Create a common Snapshot copy:

```
destination::>snapmirror update -destination-path vs1_dst:/cg/cg_dst
```

2. Monitor the progress of the update:

```
destination::>snapmirror show -fields -newest-snapshot
```

= Perform a planned failover

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can perform a planned failover to test your disaster recovery configuration or to perform maintenance on the primary cluster.

Before you begin

- The relationship must be in sync
- Nondisruptive operations must not be running
- The ONTAP Mediator must be configured, connected, and in quorum

About this task

A planned failover is initiated by the administrator of the secondary cluster. The operation requires switching the primary and secondary roles so that the secondary cluster takes over from the primary. The new primary cluster can then begin processing input and output requests locally without disrupting client operations.

Steps

1. Start the failover operation:

```
destination::>snapmirror failover start -destination-path  
vs1_dst:/cg/cg_dst
```

2. Monitor the progress of the failover:

```
destination::>snapmirror failover show
```

3. When the failover operation is complete, you can monitor the Synchronous SnapMirror protection relationship status from the destination:

```
destination::>snapmirror show
```

```
= Automatic unplanned failover operations
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

An automatic unplanned failover (AUFO) operation occurs when the primary cluster is down or isolated. When this occurs, the secondary cluster is converted to the primary and begins serving clients. This operation is performed only with assistance from the ONTAP Mediator.

After the automatic unplanned failover, it is important to rescan the host LUN I/O paths so that there is no loss of I/O paths.

You can monitor the status of the automatic unplanned failover by using the `snapmirror failover show` command.

```
= Basic monitoring
```

```
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

There are several SM-BC components and operations you can monitor.

==== ONTAP mediator

During normal operation, the Mediator state should be connected. If it is in any other state, this might indicate an error condition. You can review the Event Management System (EMS) messages to determine the error and appropriate corrective actions.

EMS Name	Description
sm.mediator.added	Mediator is added successfully
sm.mediator.removed	Mediator is removed successfully
sm.mediator.unusable	Mediator is unusable due to a corrupted Mediator server
sm.mediator.misconfigured	Mediator is repurposed or the Mediator package is no longer installed on the Mediator server
sm.mediator.unreachable	Mediator is unreachable
sm.mediator.removed.force	Mediator is removed from the cluster using the "force" option
sm.mediator.cacert.expiring	Mediator certificate authority (CA) certificate is due to expire in 30 days or less
sm.mediator.serverc.expiring	Mediator server certificate is due to expire in 30 days or less

EMS Name	Description
sm.mediator.clientc.expiring	Mediator client certificate is due to expire in 30 days or less
sm.mediator.cacert.expired	Mediator certificate authority (CA) certificate has expired
sm.mediator.serverc.expired	Mediator server certificate has expired
sm.mediator.clientc.expired	Mediator client certificate has expired
sm.mediator.in.quorum	All the SM-BC records are resynchronized with Mediator

==== Planned failover operations

You can monitor status and progress of a planned failover operation using the `snapmirror failover show` command. For example:

```
ClusterB::> snapmirror failover start -destination-path vs1:/cg/dcg1
```

Once the failover operation is complete, you can monitor the Synchronous SnapMirror protection status from the new destination cluster. For example:

```
ClusterA::> snapmirror show
```

You can also review the following messages to determine if there is an error and take the appropriate corrective actions.

EMS Name	Description
smbc.pfo.failed	SMBC planned failover operation failed. Destination path:
smbc.pfo.start. Destination path:	SMBC planned failover operation started

==== Automatic unplanned failover operations

During an unplanned automatic failover, you can monitor the status of the operation using the `snapmirror failover show` command. For example:

```

ClusterB::> snapmirror failover show -instance
Start Time: 9/23/2020 22:03:29
    Source Path: vs1:/cg/scg3
    Destination Path: vs3:/cg/dcg3
    Failover Status: completed
    Error Reason:
        End Time: 9/23/2020 22:03:30
    Primary Data Cluster: cluster-2
    Last Progress Update: -
        Failover Type: unplanned
    Error Reason codes: -

```

You can also review the following messages to determine if there is an error and take the appropriate corrective actions.

EMS Name	Description
smbc.aufo.failed	SnapMirror automatic planned failover operation failed. Destination path:
smbc.aufo.start. Destination path:	SMBC planned failover operation started
smbc.aufo.completed:	SnapMirror automatic planned failover operation completed. Destination path:
smbc.aufo.failover.incapable	block.giveback.during.aufo

== SM-BC availability

You can check the availability of the SM-BC relationship using a series of commands, either on the primary cluster, the secondary cluster, or both.

Commands you use include the `snapmirror mediator show` command on both the primary and secondary cluster to check the connection and quorum status, the `snapmirror show` command, and the `volume show` command. For example:

```

SMBC_A::*> snapmirror mediator show
Mediator Address Peer Cluster      Connection Status Quorum Status
-----
10.236.172.86     SMBC_B           connected        true

SMBC_B::*> snapmirror mediator show
Mediator Address Peer Cluster      Connection Status Quorum Status
-----
10.236.172.86     SMBC_A           connected        true

SMBC_B::*> snapmirror show -expand

Progress
Source          Destination Mirror Relationship Total
Last
Path            Type   Path       State   Status      Progress Healthy
Updated
-----
-
vs0:/cg/cg1 XDP    vs1:/cg/cg1_dp Snapmirrored InSync  -      true
-
vs0:voll      XDP    vs1:voll_dp  Snapmirrored InSync  -      true
-
2 entries were displayed.

SMBC_A::*> volume show -fields is-smbc-master,smbc-consensus,is-smbc-failover-capable -volume voll
vserver volume is-smbc-master is-smbc-failover-capable smbc-consensus
-----
vs0    voll    true        false             Consensus

SMBC_B::*> volume show -fields is-smbc-master,smbc-consensus,is-smbc-failover-capable -volume voll_dp
vserver volume is-smbc-master is-smbc-failover-capable smbc-consensus
-----
vs1    voll_dp false       true             No-consensus

```

= Add and remove volumes in a consistency group

:hardbreaks:
:icons: font
:linkatrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

If you want to change the composition of the consistency group by adding or removing a volume, you must first delete the original relationship and then create the

consistency group again with the new composition.

This workflow applies to ONTAP 9.8 and 9.9.1. Beginning with ONTAP 9.10.1, it is recommended that you manage [consistency groups](#) through System Manager or with the ONTAP REST API.

About this task

- The composition change is not allowed when the consistency group is in the “InSync” state.
- The destination volume should be of type DP.

The new volume you add to expand the consistency group must have a pair of common Snapshot copies between the source and destination volumes.

Steps

This procedure assumes that there are two volume mappings: vol_src1 ↔ vol_dst1 and vol_src2 ↔ vol_dst2, in a consistency group relationship between the end points vs1_src:/cg/cg_src and vs1_dst:/cg/cg_dst.

1. Verify that a common Snapshot copy exists between the source and destination volumes on both the source and destination cluster:

```
source::>snapshot show -vserver vs1_src -volume vol_src3 -snapshot snapmirror*
```

```
destination::>snapshot show -vserver vs1_dst -volume vol_dst3 -snapshot snapmirror*
```

2. If no common Snapshot copy exists, create and initialize a FlexVol SnapMirror relationship:

```
destination::>snapmirror initialize -source-path vs1_src:vol_src3  
-destination-path vs1_dst:vol_dst3
```

3. Delete the zero RTO consistency group relationship:

```
destination::>snapmirror delete -destination-path vs1_dst:vol_dst3
```

4. Release the source SnapMirror relationship and retain the common Snapshot copies:

```
source::>snapmirror release -relationship-info-only true -destination-path  
vs1_dst:vol_dst3
```

5. Unmap the LUNs and delete the existing consistency group relationship:

```
destination::>lun mapping delete -vserver vs1_dst -path <lun_path> -igroup  
<igroup_name>
```

The destination LUNs are unmapped, while the LUNs on the primary copy continue to serve the host I/O.

```
destination::>snapmirror delete -destination-path vs1_dst:/cg/cg_dst
```

```
source::>snapmirror release -destination-path vs1_dst:/cg/cg_dst  
-relationship-info-only true
```

6. Create the new consistency group with the new composition:

```
destination::>snapmirror create -source-path vs1_src:/cg/cg_src  
-destination-path vs1_dst:/cg/cg_dst -cg-item-mappings vol_src1:@vol_dst1,  
vol_src2:@vol_dst2, vol_src3:@vol_dst3
```

7. Resynchronize the zero RTO consistency group relationship to ensure it is in sync:

```
destination::>snapmirror resync -destination-path vs1_dst:/cg/cg_dst
```

8. Remap the LUNs that you unmapped in Step 5:

```
destination::> lun map -vserver vs1_dst -path <lun_path> -igroup  
<igroup_name>
```

9. Rescan host LUN I/O paths to restore all paths to the LUNs.

= Convert existing relationships to SM-BC relationships

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can convert an existing zero recovery point protection (zero RPO) Synchronous SnapMirror relationship to an SM-BC zero RTO Synchronous SnapMirror consistency group relationship.

Before you begin

- A zero RPO Synchronous SnapMirror relationship exists between the primary and secondary.
- All LUNs on the destination volume are unmapped before the zero RTO SnapMirror relationship is created.
- SM-BC only supports SAN protocols (not NFS/CIFS). Ensure no constituent of the consistency group is mounted for NAS access.

About this task

- You must be a cluster and SVM administrator on the source and destination.
- You cannot convert zero RPO to zero RTO sync by changing the SnapMirror policy.
- If existing LUNs on the secondary volume are mapped, `snapmirror create` with `AutomatedFailover` policy triggers an error.
You must ensure the LUNs are unmapped before issuing the `snapmirror create` command.

Steps

1. Perform a SnapMirror update operation on the existing relationship:

```
destination::>snapmirror update -destination-path vs1_dst:vol1
```

2. Verify that the SnapMirror update completed successfully:

```
destination::>snapmirror show
```

3. Quiesce each of the zero RPO synchronous relationships:

```
destination::>snapmirror quiesce -destination-path vs1_dst:vol1
```

```
destination::>snapmirror quiesce -destination-path vs1_dst:vol2
```

4. Delete each of the zero RPO synchronous relationships:

```
destination::>snapmirror delete -destination-path vs1_dst:vol1
```

```
destination::>snapmirror delete -destination-path vs1_dst:vol2
```

5. Release the source SnapMirror relationship but retain the common Snapshot copies:

```
source::>snapmirror release -relationship-info-only true -destination-path  
vs1_dst:vol1
```

```
source::>snapmirror release -relationship-info-only true -destination-path  
vs1_dst:vol2
```

6. Create a group zero RTO Synchronous Snapmirror relationship:

```
destination::> snapmirror create -source-path vs1_src:/cg/cg_src  
-destination-path vs1_dst:/cg/cg_dst -cg-item-mappings  
vol1:@vol1,vol2:@vol2 -policy AutomatedFailover
```

7. Resynchronize the zero RTO consistency group:

```
destination::> snapmirror resync -destination-path vs1_dst:/cg/cg_dst
```

8. Rescan host LUN I/O paths to restore all paths to the LUNs.

= SM-BC upgrade and revert considerations

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You should be aware of the requirements for upgrading and reverting an SM-BC configuration.

== Upgrade

Before you can configure and use SM-BC, you must upgrade all nodes on the source and destination clusters to ONTAP 9.8 or later.

xref:./encryption-at-rest/Upgrading software on ONTAP clusters

SM-BC is not supported with mixed ONTAP 9.7 and ONTAP 9.8 clusters.

Upgrading clusters from 9.8 or 9.9.1 to 9.10.1 creates new consistency groups on both source and

destination for SM-BC relationships.

== Reverting to ONTAP 9.9.1 from ONTAP 9.10.1

To revert relationships from 9.10.1 to 9.9.1, SM-BC relationships must be deleted, followed by the 9.10.1 consistency group instance. Consistency groups cannot be deleted with an active SMBC relationship. Any FlexVol volumes that were upgraded to 9.10.1 previously associated with another Smart Container or Enterprise App in 9.9.1 or earlier will no longer be associated on revert. Deleting consistency groups does not delete the constituent volumes or volume granular snapshots. Refer to [Delete a consistency group](#) for more information on this task.

== Reverting to ONTAP 9.7 from ONTAP 9.8

When you revert from ONTAP 9.8 to ONTAP 9.7, you must be aware of the following:

- If the cluster is hosting an SM-BC destination, reverting to ONTAP 9.7 is not allowed until the relationship is broken and deleted.
- If the cluster is hosting an SM-BC source, reverting to ONTAP 9.7 is not allowed until the relationship is released.
- All user-created custom SM-BC SnapMirror policies must be deleted before reverting to ONTAP 9.7.

Steps

1. Perform a revert check from one of the clusters in the SM-BC relationship:

```
cluster::*> system node revert-to -version 9.7 -check-only
```

Example:

```
cluster::*> system node revert-to -version 9.7 -check-only
Error: command failed: The revert check phase failed. The following
issues must be resolved before revert can be completed. Bring the
data LIFs down on running vservers. Command to list the running
vservers: vserver show -admin-state running Command to list the data
LIFs that are up: network interface show -role data -status-admin up
Command to bring all data LIFs down: network interface modify {-role
data} -status-admin down
Disable snapshot policies.
    Command to list snapshot policies: "snapshot policy show".
    Command to disable snapshot policies: "snapshot policy modify
-vserver
    * -enabled false"

Break off the initialized online data-protection (DP) volumes and
delete
    Uninitialized online data-protection (DP) volumes present on the
local
node.
    Command to list all online data-protection volumes on the local
node:
```

```

volume show -type DP -state online -node <local-node-name>
    Before breaking off the initialized online data-protection
volumes,
    quiesce and abort transfers on associated SnapMirror
relationships and
    wait for the Relationship Status to be Quiesced.
    Command to quiesce a SnapMirror relationship: snapmirror quiesce
    Command to abort transfers on a SnapMirror relationship:
snapmirror
    abort
    Command to see if the Relationship Status of a SnapMirror
relationship
    is Quiesced: snapmirror show
    Command to break off a data-protection volume: snapmirror break
    Command to break off a data-protection volume which is the
destination
    of a SnapMirror relationship with a policy of type "vault":
snapmirror
    break -delete-snapshots
    Uninitialized data-protection volumes are reported by the
"snapmirror
    break" command when applied on a DP volume.
    Command to delete volume: volume delete

Delete current version snapshots in advanced privilege level.
    Command to list snapshots: "snapshot show -fs-version 9.8"
    Command to delete snapshots: "snapshot prepare-for-revert -node
<nodename>"

Delete all user-created policies of the type active-strict-sync-
mirror
    and active-sync-mirror.
    The command to see all active-strict-sync-mirror and active-sync-
mirror
    type policies is:
        snapmirror policy show -type
        active-strict-sync-mirror,active-sync-mirror
    The command to delete a policy is :
        snapmirror policy delete -vserver <vserver-name> -policy
        <policy-name>

```

For information on reverting clusters, see [Revert ONTAP](#).

= Remove an SM-BC configuration
:hardbreaks:
:icons: font

```
:linkatrrs:  
:relative_path: ./smbc/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

You can remove zero RTO Synchronous SnapMirror protection and delete the SM-BC relationship configuration.

About this task

Before you delete the SM-BC relationship, all LUNs in the destination cluster must be unmapped. After the LUNs are unmapped and the host is rescanned, the SCSI target notifies the hosts that the LUN inventory has changed. The existing LUNs on the zero RTO secondary volumes change to reflect a new identity after the zero RTO relationship is deleted. Hosts discover the secondary volume LUNs as new LUNs that have no relationship to the source volume LUNs.

The secondary volumes remain DP volumes after the relationship is deleted. You can issue the snapmirror break command to convert them to read/write.

Deleting the relationship is not allowed in the failed-over state when the relationship is not reversed.

Steps

1. Delete the SM-BC consistency group relationship between the source endpoint and destination endpoint:

```
Destination::>snapmirror delete -destination-path vs1_dst:/cg/cg_dst
```

2. From the source cluster, release the consistency group relationship and the Snapshot copies created for the relationship:

```
Source::>snapmirror release -destination-path vs1_dst:/cg/cg_dst
```

3. Perform a host rescan to update the LUN inventory.
4. Beginning with ONTAP 9.10.1, deleting the SnapMirror relationship does not delete the consistency group. If you want to delete the consistency group, you must use System Manager or the ONTAP REST API. See [Delete a consistency group](#) for more information.

= Remove ONTAP Mediator

```
:hardbreaks:  
:icons: font  
:linkatrrs:  
:relative_path: ./smbc/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

If you want to remove an existing ONTAP Mediator configuration from your ONTAP clusters, you can do so by using the snapmirror mediator remove command.

Steps

1. Remove ONTAP Mediator:

```
snapmirror mediator remove -mediator-address 12.345.678.90 -peer-cluster  
cluster_xyz
```

= Troubleshooting

= SnapMirror delete operation fails in takeover state

```
:hardbreaks:  
:icons: font  
:linkatrrs:  
:relative_path: ./smbc/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/
```

Issue:

When ONTAP 9.9.1 is installed on a cluster, executing the `snapmirror delete` command fails when an SM-BC consistency group relationship is in takeover state.

Example:

```
C2_cluster::> snapmirror delete vs1:/cg/dd  
  
Error: command failed: RPC: Couldn't make connection
```

Solution

When the nodes in an SM-BC relationship are in takeover state, perform the SnapMirror delete and release operation with the "-force" option set to true.

Example:

```
C2_cluster::> snapmirror delete vs1:/cg/dd -force true  
  
Warning: The relationship between source "vs0:/cg/ss" and destination  
"vs1:/cg/dd" will be deleted, however the items of the  
destination  
Consistency Group might not be made writable, deletable, or  
modifiable  
after the operation. Manual recovery might be required.  
Do you want to continue? {y|n}: y  
Operation succeeded: snapmirror delete for the relationship with  
destination "vs1:/cg/dd".
```

= Failure creating a SnapMirror relationship and initializing consistency group

```
:hardbreaks:  
:icons: font  
:linkatrrs:  
:relative_path: ./smbc/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/
```

Issue:

Creation of SnapMirror relationship and consistency group initialization fails.

Solution:

If you are using ONTAP 9.8 or 9.9.1, ensure that the configuration has no more than 5 consistency groups. Beginning with ONTAP 9.10.1, the limit is 20. See [Additional restrictions and limitations](#).

Error:

If the consistency group is stuck initializing, check the status of your consistency group initializations with the ONTAP REST API, System Manager or the command `sn show -expand`.

Solution:

If consistency groups fail to initialize, remove the SM-BC relationship, delete the consistency group, then recreate the relationship and initialize it. This workflow differs depending on the version of ONTAP you are using.

If you are using ONTAP 9.8-9.9.1	If you are using ONTAP 9.10.1
<ol style="list-style-type: none">1. Remove the SM-BC configuration2. Create a consistency group relationship3. Initialize the consistency group relationship	<ol style="list-style-type: none">1. Under Protection > Relationships, find the SM-BC relationship on the consistency group. Select , then Delete to remove the SM-BC relationship.2. Delete the consistency group3. Configure the consistency group

= Planned failover unsuccessful

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Issue:

After executing the `snapmirror failover start` command, the output for the `snapmirror failover show` command displays a message indicates that a nondisruptive operation is in progress.

Example:

```
Cluster1::> snapmirror failover show
Source Destination Error
Path Path Type Status start-time end-time Reason
----- -----
----- 
vs1:/cg/cg vs0:/cg/cg planned failed 10/1/2020 10/1/2020 SnapMirror
Failover cannot start because a volume move is running. Retry the
command once volume move has finished.
08:35:04
08:35:04
```

Cause:

Planned failover cannot begin when a nondisruptive operation is in progress, including volume move, aggregate relocation, and storage failover.

Solution:

Wait for the nondisruptive operation to complete and try the failover operation again.

= Mediator not reachable or Mediator quorum status is false
:hardbreaks:
:icons: font
:linkatrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Issue:

After executing the snapmirror failover start command, the output for the snapmirror failover show command displays a message indicating that Mediator is not configured.

See [Initialize the ONTAP Mediator](#).

Example:

```
Cluster1::> snapmirror failover show
Source Destination Error
Path Path Type Status start-time end-time Reason
----- -----
----- 
vs0:/cg/cg vs1:/cg/cg planned failed 10/1/2020 10/1/2020 SnapMirror
failover cannot start because the source-side precheck failed. reason:
Mediator not configured.
05:50:42 05:50:43
```

Cause:

Mediator is not configured or there are network connectivity issues.

Solution:

If Mediator is not configured, you must configure Mediator before you can establish an SM-BC relationship. Fix any network connectivity issues. Make sure Mediator is connected and quorum status is true on both the source and destination site using the snapmirror mediator show command.

Example:

```
cluster::> snapmirror mediator show
Mediator Address Peer Cluster Connection Status Quorum Status
----- -----
10.234.10.143 cluster2 connected true
```

= Automatic unplanned failover not triggered on Site B

:hardbreaks:
:icons: font
:linkatrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Issue:

A failure on Site A does not trigger an unplanned failover on Site B.

Possible cause #1:

Mediator is not configured. To determine if this is the cause, issue the snapmirror mediator show command on the Site B cluster.

Example:

```
Cluster2::*> snapmirror mediator show  
This table is currently empty.
```

This example indicates that Mediator is not configured on Site B.

Solution:

Ensure that Mediator is configured on both clusters, that the status is connected, and quorum is set to True.

Possible cause #2:

SnapMirror consistency group is out of sync. To determine if this is the cause, view the event log to view if the consistency group was in sync during the time at which the Site A failure occurred.

Example:

```
cluster::*> event log show -event *out.of.sync*  
  
Time                 Node                 Severity         Event  
-----  
-----  
10/1/2020 23:26:12 sti42-vsimg-ucs511w ERROR  
sms.status.out.of.sync: Source volume "vs0:zrto_cg_556844_511u_RW1" and  
destination volume "vs1:zrto_cg_556881_511w_DP1" with relationship UUID  
"55ab7942-03e5-11eb-ba5a-005056a7dc14" is in "out-of-sync" status due  
to the following reason: "Transfer failed."
```

Solution:

Complete the following steps to perform a forced failover on Site B.

1. Unmap all LUNs belonging to the consistency group from Site B.
2. Delete the SnapMirror consistency group relationship using the `force` option.
3. Enter the `snapmirror break` command on the consistency group constituent volumes to convert volumes from DP to R/W, to enable I/O from Site B.
4. Boot up the Site A nodes to create a zero RTO relationship from Site B to Site A.
5. Release the consistency group with `relationship-info-only` on Site A to retain common Snapshot copy and unmap the LUNs belonging to the consistency group.
6. Convert volumes on Site A from R/W to DP by setting up a volume level relationship using either the Sync policy or Async policy.

7. Issue the `snapmirror resync` to synchronize the relationships.
8. Delete the SnapMirror relationships with the Sync policy on Site A.
9. Release the SnapMirror relationships with Sync policy using `relationship-info-only true` on Site B.
10. Create a consistency group relationship from Site B to Site A.
11. Perform a consistency group resync from Site A, and then verify that the consistency group is in sync.
12. Rescan host LUN I/O paths to restore all paths to the LUNs.

= Link between Site B and Mediator down and Site A down

Snapmirrored OutOfSync - false -
vs0:zrto_cg_655748_188b_RW2 XDP vs1:zrto_cg_655776_188d_DP2
Snapmirrored OutOfSync - false -
5 entries were displayed.

Site B cluster is unable to reach Site A.
C2_cluster::>*> cluster peer show
Peer Cluster Name      Cluster Serial Number Availability
Authentication
-----
C1_cluster            1-80-000011      Unavailable      ok
```

Solution

Force a failover to enable I/O from Site B and then establish a zero RTO relationship from Site B to Site A.

Complete the following steps to perform a forced failover on Site B.

1. Unmap all LUNs belonging to the consistency group from Site B.
2. Delete the SnapMirror consistency group relationship using the force option.
3. Enter the snapmirror break command on the consistency group constituent volumes to convert volumes from DP to RW, to enable I/O from Site B.
4. Boot up the Site A nodes to create a zero RTO relationship from Site B to Site A.

5. Release the consistency group with relationship-info-only on Site A to retain common Snapshot copy and unmap the LUNs belonging to the consistency group.
6. Convert volumes on Site A from RW to DP by setting up a volume level relationship using either Sync policy or Async policy.
7. Issue the snapmirror resync to synchronize the relationships.
8. Delete the SnapMirror relationships with Sync policy on Site A.
9. Release the SnapMirror relationships with Sync policy using relationship-info-only true on Site B.
10. Create a consistency group relationship from Site B to Site A.
11. Perform a consistency group resync from Site A, and then verify that the consistency group is in sync.
12. Rescan host LUN I/O paths to restore all paths to the LUNs.

= Link between Site A and Mediator down and Site B down

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

Determining the cause:

Check the status of Mediator from Site A.

Example:

```
C1_cluster::>*> snapmirror mediator show
Mediator Address Peer Cluster      Connection Status Quorum Status
----- ----- ----- ----- -----
10.237.86.17      C2_cluster      unreachable      true

C1_cluster::>*> snapmirror list-destinations
                                         Progress
Source          Destination          Transfer   Last
Relationship
Path           Type    Path          Status  Progress   Updated   Id
----- ----- ----- ----- -----
----- 
vs0:/cg/src_cg_1  XDP    vs1:/cg/dst_cg_1  OutOfSync -         -
bba7d354-06f6-11eb-9138-005056acec19
```

Check Site B connectivity:

```
C1_sti78-vs1m-ucs188a_cluster::*> cluster peer show
Peer Cluster Name          Cluster Serial Number Availability
Authentication

-----
-----
C2_cluster                1-80-000011           Unavailable      ok
```

Check the consensus status on SM-BC volume:

```
C1_cluster::*> volume show zrto_cg_894191_188b_RW1 -fields smbc-
consensus
vserver volume           smbc-consensus
-----
vs0         zrto_cg_894191_188b_RW1 Awaiting-consensus
```

Solution:

Complete the following steps to override SM-BC consensus and forcefully resume I/O on Site A:

1. Unmap the LUNs on Site A.
2. Issue the snapmirror release command using the `-force` and `override-smbc-consensus` option on Site A.
3. Remap the LUNs.
4. First, bring up Mediator, and then bring up the Site B nodes.
5. Resync the consistency group relationship using `snapmirror resync`.
6. After Site B is up, verify that the consistency group relationship is up and is in sync.
7. Perform a LUN rescan on the host to restore all paths to the LUNs.

= SM-BC SnapMirror delete operation fails when fence is set on destination volume

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./smbc/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Issue:

SnapMirror delete operation fails when any of the destination volumes have redirection fence set.

Solution

Performing the following operations to retry the redirection and remove the fence from the destination volume.

- SnapMirror resync
- SnapMirror update

```
= Volume move operation stuck when primary is down
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/
```

Issue:

A volume move operation is stuck indefinitely in cutover deferred state when the primary site is down in an SM-BC relationship.

When the primary site is down, the secondary site performs an automatic unplanned failover (AUFO). When a volume move operation is in progress when the AUFO is triggered the volume move becomes stuck.

Solution:

Abort the volume move instance that is stuck and restart the volume move operation.

```
= SnapMirror release fails when unable to delete Snapshot copy
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/
```

Issue:

The SnapMirror release operation fails when the Snapshot copy cannot be deleted.

Solution:

The Snapshot copy contains a transient tag. Use the `snapshot delete` command with the `-ignore-owners` option to remove the transient Snapshot copy.

```
snapshot delete -volume <volume_name> -snapshot <snapshot_name> -ignore-owners true -force true
```

Retry the `snapmirror release` command.

```
= Volume move reference Snapshot copy shows as the newest
:hardbreaks:
:icons: font
:linkatrrs:
:relative_path: ./smbc/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/
```

Issue:

After performing a volume move operation on a consistency group volume, the volume move reference Snapshot copy might display as the newest for the SnapMirror relationship.

You can view the newest Snapshot copy with the following command:

```
snapmirror show -fields newest-snapshot status -expand
```

Solution:

Manually perform a `snapmirror resync` or wait for the next automatic resync operation after the volume move operation completes.

= Manage MetroCluster sites with System Manager

= MetroCluster site management overview with System Manager

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source./encryption-at-rest./media/

Beginning with ONTAP 9.8, you can use System Manager as a simplified interface for managing a configuration of a MetroCluster setup.

A MetroCluster configuration allows two clusters to mirror data to each other so if one cluster goes down, the data isn't lost.

Typically, an organization sets up the clusters in two separate geographical locations. An administrator at each location sets up a cluster and configures it. Then one of the administrators can set up the peering between the clusters so that they can share data.

The organization can also install an ONTAP Mediator in a third location. The ONTAP Mediator service monitors the status of each cluster. When one of the clusters detects that it cannot communicate with the partner cluster, it queries the monitor to determine if the error is a problem with the cluster system or with the network connection.

If the problem is with the network connection, the system administrator performs troubleshooting methods to correct the error and reconnect. If the partner cluster is down, the other cluster initiates a switchover process to control the data I/O for both clusters.

You can also perform a switchover to bring down one of the cluster systems for planned maintenance. The partner cluster handles all data I/O operations for both clusters until you bring up the cluster on which you performed maintenance and perform a switchback operation.

You can manage the following operations:

- Set up an IP MetroCluster site
- Set up IP MetroCluster peering
- Configure an IP MetroCluster site
- Perform IP MetroCluster switchover and switchback
- Troubleshoot problems with IP MetroCluster configurations
- Upgrade ONTAP on MetroCluster clusters

= Set up an IP MetroCluster site

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

```
:linkatrrs:  
:relative_path: ./  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

Beginning with ONTAP 9.8, you can use System Manager to set up an IP configuration of a MetroCluster site.

A MetroCluster site consists of two clusters. Typically, the clusters are located in different geographical locations.

Before you start

- Your system should already be installed and cabled according to the [Installation and Setup Instructions](#) that came with the system.
- Cluster network interfaces should be configured on each node of each cluster for intra-cluster communication.

== Assign a node-management IP address

==== Windows System

You should connect your Windows computer to the same subnet as the controllers. This will automatically assign a node-management IP address to your system.

Steps

1. From the Windows system, open the **Network** drive to discover the nodes.
2. Double-click the node to launch the cluster setup wizard.

==== Other systems

You should configure the node-management IP address for one of the nodes in your cluster. You can use this node-management IP address to launch the cluster set up wizard.

See [Creating the cluster on the first node](#) for information about assigning a node-management IP address.

== Initialize and configure the cluster

You initialize the cluster by setting an administrative password for the cluster and setting up the cluster management and node management networks. You can also configure services like a DNS server to resolve host names and an NTP server to synchronize time.

Steps

1. On a web browser, enter the node-management IP address that you have configured: "https://node-management-IP"

System Manager automatically discovers the remaining nodes in the cluster.

2. In the **Initialize Storage System** window, perform the following:

- a. Enter cluster management network configuration data.
 - b. Enter Node management IP addresses for all the nodes.
 - c. Provide domain name servers (DNS) details.
- d. In the **Other** section, select the check box labeled **Use time service (NTP)** to add the time servers.

When you click **Submit**, wait for the cluster to be created and configured. Then, a validation process occurs.

What's Next?

After both clusters have been set up, initialized, and configured, perform the following procedure:

- [Set up IP MetroCluster peering](#)

== Configure ONTAP on a new cluster video

= Set up IP MetroCluster peering

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

Beginning with ONTAP 9.8, you can manage an IP configuration of a MetroCluster operation with System Manager. After setting up two clusters, you set up peering between them.

Before you start

You should have completed the following procedure to set up two clusters:

- [Set up an IP MetroCluster site](#)

Certain steps of this process are performed by different system administrators located at the geographical sites of each cluster. For the purposes of explaining this process, the clusters are called "Site A cluster" and "Site B cluster".

== Performing the peering process from Site A

This process is performed by a system administrator at Site A.

Steps

1. Log in to Site A cluster.
2. In System Manager, select **Dashboard** from the left navigation column to display the cluster overview.

The dashboard shows the details for this cluster (Site A). In the **MetroCluster** section, Site A cluster is shown on the left.

3. Click **Attach Partner Cluster**.
4. Enter the details of the network interfaces that allow the nodes in Site A cluster to communicate with the nodes in Site B cluster.
5. Click **Save and Continue**.
6. On the **Attach Partner Cluster** window, select **I do not have a passphrase**, which lets you generate a passphrase.
7. Copy the generated passphrase and share it with the system administrator at Site B.
8. Select **Close**.

== Performing the peering process from Site B

This process is performed by a system administrator at Site B.

Steps

1. Log in to Site B cluster.
2. In System Manager, select **Dashboard** to display the cluster overview.

The dashboard shows the details for this cluster (Site B). In the MetroCluster section, Site B cluster is shown on the left.

3. Click **Attach Partner Cluster** to start the peering process.
4. Enter the details of the network interfaces that allow the nodes in Site B cluster to communicate with the nodes in Site A cluster.
5. Click **Save and Continue**.
6. On the **Attach Partner Cluster** window, select **I have a passphrase**, which lets you enter the passphrase that you received from the system administrator at Site A.
7. Select **Peer** to complete the peering process.

What's next?

After the peering process is successfully completed, you configure the clusters. See [Configure an IP MetroCluster site](#).

= Configure an IP MetroCluster site

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrs:

```
:relative_path: ./  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

Beginning with ONTAP 9.8, you can manage an IP configuration of a MetroCluster operation with System Manager. After setting up two clusters and peering them, you configure each cluster.

Before you start

You should have completed the following procedures:

- [Set up an IP MetroCluster site](#)
- [Set up IP MetroCluster peering](#)

== Configure the connection between clusters

Steps

1. Log in to System Manager on one of the sites, and select **Dashboard**.

In the **MetroCluster** section, the graphic shows the two clusters that you set up and peered for the MetroCluster sites. The cluster you are working from (local cluster) is shown on the left.

2. Click **Configure MetroCluster**. From this window, you can perform the following tasks:

- a. The nodes for each cluster in the MetroCluster configuration are shown. Use the drop-down lists to select which nodes in the local cluster will be disaster recovery partners with which nodes in the remote cluster.
- b. Click the check box if you want to configure an ONTAP Mediator service. See [\[Configure the ONTAP Mediator service\]](#).
- c. If both clusters have a license to enable encryption, the **Encryption** section is displayed.

To enable encryption, enter a passphrase.

- d. Click the check box if you want to configure MetroCluster with shared layer 3 network.

The HA partner nodes and network switches connecting to the nodes must have a matching configuration.

3. Click **Save** to configure the MetroCluster sites.

On the **Dashboard**, in the **MetroCluster** section, the graphic shows a check mark on the link between the two clusters, indicating a healthy connection.

== Configure the ONTAP Mediator service

The ONTAP Mediator service is typically installed at a geographic location separate from either location of the clusters. The clusters communicate regularly with the service to indicate that they are up and running. If one of the clusters in the MetroCluster configuration detects that the communication with its partner cluster is down, it checks with the ONTAP Mediator to determine if the partner cluster itself is down.

Before you start

Both clusters at the MetroCluster sites should be up and peered.

Steps

1. In System Manager in ONTAP 9.8, select **Cluster > Settings**.
2. In the **Mediator** section, click .
3. On the **Configure Mediator** window, click **Add+**.
4. Enter the configuration details for the ONTAP Mediator.

= Perform IP MetroCluster switchover and switchback

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

:linkatrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

You can switch over control from one IP MetroCluster site to the other to perform maintenance or recover from an issue.

Switchover and switchback procedures are supported only for IP MetroCluster configurations.

== Overview of switchover and switchback

A switchover can occur in two instances:

- **A planned switchover**

This switchover is initiated by a system administrator using System Manager. The planned switchover allows a system administrator of a local cluster to switch control so that the data services of the remote cluster are handled by the local cluster. Then, a system administrator at the remote cluster location can perform maintenance on the remote cluster.

- **An unplanned switchover**

In some cases, when a MetroCluster cluster goes down or the connections between the clusters are down, ONTAP will automatically initiate a switchover procedure so that the cluster that is still running handles the data handling responsibilities of the down cluster.

At other times, when ONTAP cannot determine the status of one of the clusters, the system administrator of the site that is working initiates the switchover procedure to take control of the data handling responsibilities of the other site.

For any type of switchover procedure, the data servicing capability is returned to the cluster by using a *switchback* process.

You perform different switchover and switchback processes for ONTAP 9.7 and 9.8:

- [Use System Manager in ONTAP 9.7 for switchover and switchback](#)
- [Use System Manager in ONTAP 9.8 for switchover and switchback](#)

== Use System Manager in ONTAP 9.7 for switchover and switchback

Steps

1. Log in to System Manager in ONTAP 9.7.
2. Click **(Return to classic version)**.
3. Click **Configuration > MetroCluster**.

System Manager verifies whether a negotiated switchover is possible.

4. Perform one of the following substeps when the validation process has completed:
 - a. If validation fails, but Site B is up, then an error has occurred. For example, there might be a problem with a subsystem, or NVRAM mirroring might not be synchronized.
 - i. Fix the issue that is causing the error, click **Close**, and then start again at Step 2.
 - ii. Halt the Site B nodes, click **Close**, and then perform the steps in [Performing an unplanned switchover](#).
 - b. If validation fails, and Site B is down, then most likely there is a connection problem. Verify that Site B is really down, then perform the steps in [Performing an unplanned switchover](#).
5. Click **Switchover from Site B to Site A** to initiate the switchover process.
6. Click **Switch to the new experience**.

== Use System Manager in ONTAP 9.8 for switchover and switchback

==== Perform a planned switchover (ONTAP 9.8)

Steps

1. Log in to System Manager in ONTAP 9.8.
2. Select **Dashboard**. In the **MetroCluster** section, the two clusters are shown with a connection.
3. In the local cluster (shown on the left), click , and select **Take control of remote site**.

After the switchover request is validated, control is transferred from the remote site to the local site, which performs data service requests for both clusters.

The remote cluster reboots, but the storage components are not active, and the cluster does not service data requests. It is now available for planned maintenance.

The remote cluster should not be used for data servicing until you perform a switchback.

==== Perform an unplanned switchover (ONTAP 9.8)

An unplanned switchover might be initiated automatically by ONTAP. If ONTAP cannot determine if a switchback is needed, the system administrator of the MetroCluster site that is still running initiates the switchover with the following steps:

Steps

1. Log in to System Manager in ONTAP 9.8.
2. Select **Dashboard**.

In the **MetroCluster** section, the connection between the two clusters is shown with an "X" on it, meaning a connection cannot be detected. Either the connections or the cluster is down.

3. In the local cluster (shown on the left), click , and select **Take control of remote site**.

After the switchover request is validated, control is transferred from the remote site to the local site, which performs data service requests for both clusters.

The cluster must be repaired before it is brought online again.

After the remote cluster is brought online again, it should not be used for data servicing until you perform a switchback.

== Perform a switchback (ONTAP 9.8)

Before you start

Whether the remote cluster was down due to planned maintenance or due to a disaster, it should now be up and running and waiting for the switchback.

Steps

1. On the local cluster, log in to System Manager in ONTAP 9.8.
2. Select **Dashboard**.

In the **MetroCluster** section, the two clusters are shown.

3. In the local cluster (shown on the left), click , and select **Take back control**.

The data is *healed* first, to ensure data is synchronized and mirrored between both clusters.

4. When the data healing is complete, click , and select **Initiate switchback**.

When the switchback is complete, both clusters are active and servicing data requests. Also, the data is being mirrored and synchronized between the clusters.

= Modify address, netmask, and gateway in a MetroCluster IP

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

Beginning with ONTAP 9.10.1, you can change the following properties of a MetroCluster IP interface: IP address and mask, and gateway. You can use any combination of parameters to update.

You might need to update these properties, for example, if a duplicate IP address is detected or if a gateway needs to change in the case of a layer 3 network due to router configuration changes. You can only change one interface at a time. There will be traffic disruption on that interface until the other interfaces are updated and connections are reestablished.

You must make the changes on each port. Similarly, network switches also need to update their configuration. For example, if the gateway is updated, ideally it is changed on both nodes of an HA pair, since they are same. Plus the switch connected to those nodes also needs to update its gateway.

Step

Update the IP address, netmask, and gateway for each node and interface.

= Troubleshoot problems with IP MetroCluster configurations

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

Beginning with ONTAP 9.8, System Manager monitors the health of IP MetroCluster configurations and helps you identify and correct problems that might occur.

== Overview of the MetroCluster Health Check

System Manager periodically checks the health of your IP MetroCluster configuration. When you view the MetroCluster section in the Dashboard, usually the message is "MetroCluster systems are healthy."

However, when a problem occurs, the message will show the number of events. You can click on that message and view the results of the health check for the following components:

- Node
- Network Interface
- Tier (Storage)
- Cluster
- Connection
- Volume
- Configuration Replication

The **Status** column identifies which components have problems, and the **Details** column suggests how to correct the problem.

== MetroCluster troubleshooting

Steps

1. In System Manager, select **Dashboard**.
2. In the **MetroCluster** section, notice the message.
 - a. If the message indicates that your MetroCluster configuration is healthy, and the connections between the clusters and the ONTAP Mediator are healthy (shown with check marks), then you have no problems to correct.
 - b. If the message lists the number of events, or the connections have gone down (shown with an "X"), then continue to the next step.

3. Click the message that shows the number of events.

The MetroCluster Health Report displays.

4. Troubleshoot the problems that appear in the report using the suggestions in the **Details** column.
5. When all the problems have been corrected, click **Check MetroCluster Health**.

The MetroCluster Health Check uses an intensive amount of resources, so it is recommended that you perform all your troubleshooting tasks before running the check.

The MetroCluster Health Check runs in the background. You can work on other tasks while you wait for it to finish.

= Data protection using tape backup

= Tape backup of FlexVol volumes overview

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

ONTAP supports tape backup and restore through Network Data Management Protocol (NDMP). NDMP allows you to back up data in storage systems directly to tape, resulting in efficient use of network bandwidth. ONTAP supports both dump and SMTape engines for tape backup.

You can perform a dump or SMTape backup or restore by using NDMP-compliant backup applications. Only NDMP version 4 is supported.

== Tape backup using dump

Dump is a Snapshot copy based backup in which your file system data is backed up to tape. The ONTAP dump engine backs up files, directories, and the applicable access control list (ACL) information to tape. You can back up an entire volume, an entire qtree, or a subtree that is not an entire volume or an entire qtree. Dump supports baseline, differential, and incremental backups.

== Tape backup using SMTape

SMTape is a Snapshot copy based disaster recovery solution from ONTAP that backs up blocks of data to tape. You can use SMTape to perform volume backups to tapes. However, you cannot perform a backup at the qtree or subtree level. SMTape supports baseline, differential, and incremental backups.

= Tape backup and restore workflow

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can perform tape backup and restore operations by using an NDMP-enabled backup application.

About this task

The tape backup and restore workflow provides an overview of the tasks that are involved in performing

tape backup and restore operations. For detailed information about performing a backup and restore operation, see the backup application documentation.

Steps

1. Set up a tape library configuration by choosing an NDMP-supported tape topology.
2. Enable NDMP services on your storage system.

You can enable the NDMP services either at the node level or at the storage virtual machine (SVM) level. This depends on the NDMP mode in which you choose to perform the tape backup and restore operation.

3. Use NDMP options to manage NDMP on your storage system.

You can use NDMP options either at the node level or at the SVM level. This depends on the NDMP mode in which you choose to perform the tape backup and restore operation.

You can modify the NDMP options at the node level by using the `system services ndmp modify` command and at the SVM level by using the `vserver services ndmp modify` command. For more information about these commands, see the man pages.

4. Perform a tape backup or restore operation by using an NDMP-enabled backup application.

ONTAP supports both dump and SMTape engines for tape backup and restore.

For more information about using the backup application (also called *Data Management Applications* or *DMA*s) to perform backup or restore operations, see your backup application documentation.

Related information

[Common NDMP tape backup topologies](#)

[Understanding dump engine for FlexVol volumes](#)

= Use cases for choosing a tape backup engine

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

ONTAP supports two backup engines: SMTape and dump. You should be aware of the use cases for the SMTape and dump backup engines to help you choose the backup engine to perform tape backup and restore operations.

Dump can be used in the following cases:

- Direct Access Recovery (DAR) of files and directories
- Backup of a subset of subdirectories or files in a specific path
- Excluding specific files and directories during backups
- Preserving backup for long durations

SMTape can be used in the following cases:

- Disaster recovery solution

- Preserving deduplication savings and deduplication settings on the backed up data during a restore operation

- Backup of large volumes

= Manage tape drives

= Manage tape drives overview

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can verify tape library connections and view tape drive information before performing a tape backup or restore operation. You can use a nonqualified tape drive by emulating this to a qualified tape drive. You can also assign and remove tape aliases in addition to viewing existing aliases.

When you back up data to tape, the data is stored in tape files. File marks separate the tape files, and the files have no names. You specify a tape file by its position on the tape. You write a tape file by using a tape device. When you read the tape file, you must specify a device that has the same compression type that you used to write that tape file.

= Commands for managing tape drives, media changers, and tape drive operations

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

There are commands for viewing information about tape drives and media changers in a cluster, bringing a tape drive online and taking it offline, modifying the tape drive cartridge position, setting and clearing tape drive alias name, and resetting a tape drive. You can also view and reset tape drive statistics.

If you want to...	Use this command...
Bring a tape drive online	storage tape online
Clear an alias name for tape drive or media changer	storage tape alias clear
Enable or disable a tape trace operation for a tape drive	storage tape trace
Modify the tape drive cartridge position	storage tape position
Reset a tape drive	storage tape reset
	 This command is available only at the advanced privilege level.

If you want to...	Use this command...
Set an alias name for tape drive or media changer	storage tape alias set
Take a tape drive offline	storage tape offline
View information about all tape drives and media changers	storage tape show
View information about tape drives attached to the cluster	<ul style="list-style-type: none"> • storage tape show-tape-drive • system node hardware tape drive show
View information about media changers attached to the cluster	storage tape show-media-changer
View error information about tape drives attached to the cluster	storage tape show-errors
View all ONTAP qualified and supported tape drives attached to each node in the cluster	storage tape show-supported-status
View aliases of all tape drives and media changers attached to each node in the cluster	storage tape alias show
Reset the statistics reading of a tape drive to zero	<p>storage stats tape zero <i>tape_name</i></p> <p>You must use this command at the nodeshell.</p>
View tape drives supported by ONTAP	<p>storage show tape supported [-v]</p> <p>You must use this command at the nodeshell. You can use the -v option to view more details about each tape drive.</p>
View tape device statistics to understand tape performance and check usage pattern	<p>storage stats tape <i>tape_name</i></p> <p>You must use this command at the nodeshell.</p>

For more information about these commands, see the man pages.

= Use a nonqualified tape drive

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

You can use a nonqualified tape drive on a storage system if it can emulate a qualified tape drive. It is then treated like a qualified tape drive. To use a nonqualified

tape drive, you must first determine whether it emulates any of the qualified tape drives.

About this task

A nonqualified tape drive is one that is attached to the storage system, but not supported or recognized by ONTAP.

Steps

1. View the nonqualified tape drives attached to a storage system by using the `storage tape show-supported-status` command.

The following command displays tape drives attached to the storage system and the support and qualification status of each tape drive. The nonqualified tape drives are also listed.

“`tape_drive_vendor_name`” is a nonqualified tape drive attached to the storage system, but not supported by ONTAP.

cluster1::> storage tape show-supported-status -node Node1			
drive	Node: Node1		
	Tape Drive	Is Supported	Support Status
	" <code>tape_drive_vendor_name</code> "	false	Nonqualified tape
Hewlett-Packard C1533A	true	Qualified	
Hewlett-Packard C1553A	true	Qualified	
Hewlett-Packard Ultrium 1	true	Qualified	
Sony SDX-300C	true	Qualified	
Sony SDX-500C	true	Qualified	
StorageTek T9840C	true	Dynamically Qualified	
StorageTek T9840D	true	Dynamically Qualified	
Tandberg LTO-2 HH	true	Dynamically Qualified	

2. Emulate the qualified tape drive.

[NetApp Downloads: Tape Device Configuration Files](#)

Related information

= Assign tape aliases

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

For easy device identification, you can assign tape aliases to a tape drive or medium changer. Aliases provide a correspondence between the logical names of backup devices and a name permanently assigned to the tape drive or medium changer.

Steps

1. Assign an alias to a tape drive or medium changer by using the `storage tape alias set` command.

For more information about this command, see the man pages.

You can view the serial number (SN) information about the tape drives by using the `system node hardware tape drive show` command and about tape libraries by using the `system node hardware tape library show` commands.

The following command sets an alias name to a tape drive with serial number SN[123456]L4 attached to the node, cluster1-01:

```
cluster-01::> storage tape alias set -node cluster-01 -name st3  
-mapping SN[123456]L4
```

The following command sets an alias name to a media changer with serial number SN[65432] attached to the node, cluster1-01:

```
cluster-01::> storage tape alias set -node cluster-01 -name mc1  
-mapping SN[65432]
```

Related information

[What tape aliasing is](#)

[Removing tape aliases](#)

= Remove tape aliases

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./encryption-at-rest//media/

You can remove aliases by using the `storage tape alias clear` command when persistent aliases are no longer required for a tape drive or medium changer.

Steps

1. Remove an alias from a tape drive or medium changer by using the `storage tape alias clear` command.

For more information about this command, see the man pages.

The following command removes the aliases of all tape drives by specifying the scope of the alias clear operation to tape:

```
cluster-01::>storage tape alias clear -node cluster-01 -clear-scope  
tape
```

After you finish

If you are performing a tape backup or restore operation using NDMP, then after you remove an alias from a tape drive or medium changer, you must assign a new alias name to the tape drive or medium changer to continue access to the tape device.

Related information

[What tape aliasing is](#)

[Assigning tape aliases](#)

= Enabling or disabling tape reservations

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can control how ONTAP manages tape device reservations by using the `tape.reservations` option. By default, tape reservation is turned off.

About this task

Enabling the tape reservations option can cause problems if tape drives, medium changers, bridges, or libraries do not work properly. If tape commands report that the device is reserved when no other storage systems are using the device, this option should be disabled.

Steps

1. To use either the SCSI Reserve/Release mechanism or SCSI Persistent Reservationsor to disable tape reservations, enter the following commandat the clustershell:

```
options -option-name tape.reservations -option-value {scsi | persistent | off}
```

`scsi` selects the SCSI Reserve/Release mechanism.

`persistent` selects SCSI Persistent Reservations.

`off` disables tape reservations.

Related information

[What tape reservations are](#)

= Commands for verifying tape library connections

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can view information about the connection path between a storage system and a tape library configuration attached to the storage system. You can use this information to verify the connection path to the tape library configuration or for troubleshooting issues related to the connection paths.

You can view the following tape library details to verify the tape library connections after adding or creating a new tape library, or after restoring a failed path in a single-path or multipath access to a tape

library. You can also use this information while troubleshooting path-related errors or if access to a tape library fails.

- Node to which the tape library is attached
- Device ID
- NDMP path
- Tape library name
- Target port and initiator port IDs
- Single-path or multipath access to a tape library for every target or FC initiator port
- Path-related data integrity details, such as “Path Errors” and “Path Qual”
- LUN groups and LUN counts

If you want to...	Use this command...
View information about a tape library in a cluster	system node hardware tape library show
View path information for a tape library	storage tape library path show
View path information for a tape library for every initiator port	storage tape library path show-by-initiator
View connectivity information between a storage tape library and cluster	storage tape library config show

For more information about these commands, see the man pages.

= About tape drives

= Qualified tape drives overview

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You must use a qualified tape drive that has been tested and found to work properly on a storage system. You can follow tape aliasing and also enable tape reservations to ensure that only one storage system accesses a tape drive at any particular time.

A qualified tape drive is a tape drive that has been tested and found to work properly on storage systems. You can qualify tape drives for existing ONTAP releases by using the tape configuration file.

= Format of the tape configuration file

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

The tape configuration file format consists of fields such as vendor ID, product ID, and details of compression types for a tape drive. This file also consists of optional fields for enabling the autoload feature of a tape drive and changing the command

timeout values of a tape drive.

The following table displays the format of the tape configuration file:

Item	Size	Description
vendor_id (string)	up to 8 bytes	The vendor ID as reported by the SCSI Inquiry command.
product_id(string)	up to 16 bytes	The product ID as reported by the SCSI Inquiry command.
id_match_size(number)		The number of bytes of the product ID to be used for matching to detect the tape drive to be identified, beginning with the first character of the product ID in the Inquiry data.
vendor.pretty (string)	up to 16 bytes	If this parameter is present, it is specified by the string displayed by the command, storage tape show -device-names; otherwise, INQ_VENDOR_ID is displayed.
product.pretty(string)	up to 16 bytes	If this parameter is present, it is specified by the string displayed by the command, storage tape show -device-names; otherwise, INQ_PRODUCT_ID is displayed.

The vendor.pretty and product.pretty fields are optional, but if one of these fields has a value, the other must also have a value.

The following table explains the description, density code, and compression algorithm for the various compression types, such as l, m, h, and a:

Item	Size	Description
{l m h a}_description=(string)	up to 24 bytes	The string to print for the nodeshell command, sysconfig -t, that describes characteristics of the particular density setting.

Item	Size	Description
{l m h a}_density=(hex codes)		The density code to be set in the SCSI mode page block descriptor corresponding to the desired density code for l, m, h, or a.
{l m h a}_algorithm=(hex codes)		The compression algorithm to be set in the SCSI Compression Mode Page corresponding to the density code and the desired density characteristic.

The following table describes the optional fields available in the tape configuration file:

Field	Description
autoload=(Boolean yes/no)	This field is set to yes if the tape drive has an automatic loading feature; that is, after tape cartridge is inserted, the tape drive becomes ready without the need to execute a SCSI load (start/stop unit) command. The default for this field is no.
cmd_timeout_0x	Individual timeout value. You must use this field only if you want to specify a different timeout value from the one being used as a default by the tape driver. The sample file lists the default SCSI command timeout values used by the tape drive. The timeout value can be expressed in minutes (m), seconds (s), or milliseconds (ms).  You should change this field only with guidance from technical support.

You can download and view the tape configuration file from the NetApp Support Site.

Example of a tape configuration file format

The tape configuration file format for the HP LTO5 ULTRIUM tape drive is as follows:

```
vendor_id="HP"
product_id="LTO-5"
id_match_size=9
vendor_pretty="Hewlett-Packard"
product_pretty="LTO-5"
```

```
l_description="LTO-3(ro)/4 4/800GB"
l_density=0x00
l_algorithm=0x00

m_description="LTO-3(ro)/4 8/1600GB cmp"
m_density=0x00
m_algorithm=0x01

h_description="LTO-5 1600GB"
h_density=0x58
h_algorithm=0x00

a_description="LTO-5 3200GB cmp"
a_density=0x58
a_algorithm=0x01

autoload="yes"
```

Related information

[NetApp Downloads: Tape Device Configuration Files](#)

= How the storage system qualifies a new tape drive dynamically
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

The storage system qualifies a tape drive dynamically by matching its vendor ID and product ID with the information contained in the tape qualification table.

When you connect a tape drive to the storage system, it looks for a vendor ID and product ID match between the information obtained during tape discovery and the information in the internal tape qualification table. If the storage system discovers a match, it marks the tape drive as qualified and can access the tape drive. If the storage system cannot find a match, the tape drive remains in the unqualified state and is not accessed.

= Tape devices overview

= Tape devices overview
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

A tape device is a representation of a tape drive. It is a specific combination of rewind type and compression capability of a tape drive.

A tape device is created for each combination of rewind type and compression capability. Therefore, a tape drive or tape library can have several tape devices associated with it. You must specify a tape device to move, write, or read tapes.

When you install a tape drive or tape library on a storage system, ONTAP creates tape devices associated with the tape drive or tape library.

ONTAP detects tape drives and tape libraries and assigns logical numbers and tape devices to them. ONTAP detects the Fibre Channel, SAS, and parallel SCSI tape drives and libraries when they are connected to the interface ports. ONTAP detects these drives when their interfaces are enabled.

= Tape device name format

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

Each tape device has an associated name that appears in a defined format. The format includes information about the type of device, rewind type, alias, and compression type.

The format of a tape device name is as follows:

rewind_type st alias_number compression_type

rewind_type is the rewind type.

The following list describes the various rewind type values:

- **r**

ONTAP rewinds the tape after it finishes writing the tape file.

- **nr**

ONTAP does not rewind the tape after it finishes writing the tape file. You must use this rewind type when you want to write multiple tape files on the same tape.

- **ur**

This is the unload/reload rewind type. When you use this rewind type, the tape library unloads the tape when it reaches the end of a tape file, and then loads the next tape, if there is one.

You must use this rewind type only under the following circumstances:

- The tape drive associated with this device is in a tape library or is in a medium changer that is in the library mode.
- The tape drive associated with this device is attached to a storage system.
- Sufficient tapes for the operation that you are performing are available in the library tape sequence defined for this tape drive.

If you record a tape using a no-rewind device, you must rewind the tape before you read it.

st is the standard designation for a tape drive.

`alias_number` is the alias that ONTAP assigns to the tape drive. When ONTAP detects a new tape drive, ONTAP assigns an alias to the tape drive.

`compression_type` is a drive-specific code for the density of data on the tape and the type of compression.

The following list describes the various values for `compression_type`:

- **a**

Highest compression

- **h**

High compression

- **m**

Medium compression

- **l**

Low compression

Examples

`nrst0a` specifies a no-rewind device on tape drive 0 using the highest compression.

Example of a listing of tape devices

The following example shows the tape devices associated with HP Ultrium 2-SCSI:

```
Tape drive (fc202_6:2.126L1)  HP      Ultrium 2-SCSI
rst01 - rewind device,          format is: HP (200GB)
nrst01 - no rewind device,     format is: HP (200GB)
urst01 - unload/reload device, format is: HP (200GB)
rst0m - rewind device,         format is: HP (200GB)
nrst0m - no rewind device,     format is: HP (200GB)
urst0m - unload/reload device, format is: HP (200GB)
rst0h - rewind device,         format is: HP (200GB)
nrst0h - no rewind device,     format is: HP (200GB)
urst0h - unload/reload device, format is: HP (200GB)
rst0a - rewind device,         format is: HP (400GB w/comp)
nrst0a - no rewind device,     format is: HP (400GB w/comp)
urst0a - unload/reload device, format is: HP (400GB w/comp)
```

The following list describes the abbreviations in the preceding example:

- GB—Gigabytes; this is the capacity of the tape.
- w/comp—With compression; this shows the tape capacity with compression.

= Supported number of simultaneous tape devices
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

ONTAP supports a maximum of 64 simultaneous tape drive connections, 16 medium changers, and 16 bridge or router devices for each storage system (per node) in any mix of Fibre Channel, SCSI, or SAS attachments.

Tape drives or medium changers can be devices in physical or virtual tape libraries or stand-alone devices.

Although a storage system can detect 64 tape drive connections, the maximum number of backup and restore sessions that can be performed simultaneously depends upon the scalability limits of the backup engine.

Related information

[Scalability limits for dump backup and restore sessions](#)

= Tape aliasing

= Tape aliasing overview

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Aliasing simplifies the process of device identification. Aliasing binds a physical path name (PPN) or a serial number (SN) of a tape or a medium changer to a persistent, but modifiable alias name.

The following table describes how tape aliasing enables you to ensure that a tape drive (or tape library or medium changer) is always associated with a single alias name:

Scenario	Reassigning of the alias
When the system reboots	The tape drive is automatically reassigned its previous alias.
When a tape device moves to another port	The alias can be adjusted to point to the new address.
When more than one system uses a particular tape device	The user can set the alias to be the same for all the systems.

When you upgrade from Data ONTAP 8.1.x to Data ONTAP 8.2.x, the tape alias feature of Data ONTAP 8.2.x modifies the existing tape alias names. In such a case you might have to update the tape alias names in the backup application.

Assigning tape aliases provides a correspondence between the logical names of backup devices (for example, st0 or mc1) and a name permanently assigned to a port, a tape drive, or a medium changer.

st0 and st00 are different logical names.

Logical names and serial numbers are used only to access a device. After the device is accessed, it returns all error messages by using the physical path name.

There are two types of names available for aliasing: physical path name and serial number.

= What physical path names are

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

Physical path names (PPNs) are the numerical address sequences that ONTAP assigns to tape drives and tape libraries based on the SCSI-2/3 adapter or switch (specific location) they are connected to the storage system. PPNs are also known as electrical names.

PPNs of direct-attached devices use the following format: host_adapter.device_id_lun

The LUN value is displayed only for tape and medium changer devices whose LUN values are not zero; that is, if the LUN value is zero the lun part of the PPN is not displayed.

For example, the PPN 8.6 indicates that the host adapter number is 8, the device ID is 6, and the logical unit number (LUN) is 0.

SAS tape devices are also direct-attached devices. For example, the PPN 5c.4 indicates that in a storage system, the SAS HBA is connected in slot 5, SAS tape is connected to port C of the SAS HBA, and the device ID is 4.

PPNs of Fibre Channel switch-attached devices use the following format: switch:port_id.device_id_lun

For example, the PPN MY_SWITCH:5.3L2 indicates that the tape drive connected to port 5 of a switch called MY_SWITCH is set with device ID 3 and has the LUN 2.

The LUN (logical unit number) is determined by the drive. Fibre Channel, SCSI tape drives and libraries, and disks have PPNs.

PPNs of tape drives and libraries do not change unless the name of the switch changes, the tape drive or library moves, or the tape drive or library is reconfigured. PPNs remain unchanged after reboot. For example, if a tape drive named MY_SWITCH:5.3L2 is removed and a new tape drive with the same device ID and LUN is connected to port 5 of the switch MY_SWITCH, the new tape drive would be accessible by using MY_SWITCH:5.3L2.

= What serial numbers are

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

A serial number (SN) is a unique identifier for a tape drive or a medium changer. ONTAP generates aliases based on SN instead of the WWN.

Since the SN is a unique identifier for a tape drive or a medium changer, the alias remains the same regardless of the multiple connection paths to the tape drive or medium changer. This helps storage systems to track the same tape drive or medium changer in a tape library configuration.

The SN of a tape drive or a medium changer does not change even if you rename the Fibre Channel switch to which the tape drive or medium changer is connected. However, in a tape library if you replace an existing tape drive with a new one, then ONTAP generates new aliases because the SN of the tape drive changes. Also, if you move an existing tape drive to a new slot in a tape library or remap the tape drive's LUN, ONTAP generates a new alias for that tape drive.

You must update the backup applications with the newly generated aliases.

The SN of a tape device uses the following format: SN [xxxxxxxxxx] L [X]

x is an alphanumeric character and LX is the LUN of the tape device. If the LUN is 0, the LX part of the string is not displayed.

Each SN consists of up to 32 characters; the format for the SN is not case-sensitive.

= Considerations when configuring multipath tape access

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can configure two paths from the storage system to access the tape drives in a tape library. If one path fails, the storage system can use the other paths to access the tape drives without having to immediately repair the failed path. This ensures that tape operations can be restarted.

You must consider the following when configuring multipath tape access from your storage system:

- In tape libraries that support LUN mapping, for multipath access to a LUN group, LUN mapping must be symmetrical on each path.

Tape drives and media changers are assigned to LUN groups (set of LUNs that share the same initiator path set) in a tape library. All tape drives of a LUN group must be available for backup and restore operations on all multiple paths.

- A maximum of two paths can be configured from the storage system to access the tape drives in a tape library.
- Multipath tape access supports load balancing. Load balancing is disabled by default.

In the following example, the storage system accesses LUN group 0 through two initiator paths: 0b and 0d. In both these paths, the LUN group has the same LUN number, 0, and LUN count, 5. The storage system accesses LUN group 1 through only one initiator path, 3d.

```

= How you add tape drives and libraries to storage systems

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can add tape drives and libraries to storage system dynamically (without taking the storage system offline).

When you add a new medium changer, the storage system detects its presence and adds it to the configuration. If the medium changer is already referenced in the alias information, no new logical names are created. If the library is not referenced, the storage system creates a new alias for the medium changer.

In a tape library configuration, you must configure a tape drive or medium changer on LUN 0 of a target port for ONTAP to discover all medium changers and tape drives on that target port.

= What tape reservations are

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Multiple storage systems can share access to tape drives, medium changers, bridges, or tape libraries. Tape reservations ensure that only one storage system accesses a device at any particular time by enabling either the SCSI Reserve/Release mechanism or SCSI Persistent Reservations for all tape drives, medium changers, bridges, and tape libraries.

All the systems that share devices in a library, whether switches are involved or not, must use the same reservation method.

The SCSI Reserve/Release mechanism for reserving devices works well under normal conditions.

However, during interface error recovery procedures, reservations can be lost. If this occurs, initiators other than the reserved owner can access the device.

Reservations made with SCSI Persistent Reservations are not affected by error recovery mechanisms, such as loop reset or target reset; however, not all devices implement SCSI Persistent Reservations correctly.

= Transfer data using `ndmpcopy`

= Transfer data using `ndmpcopy` overview

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

The `ndmpcopy` nodeshell command transfers data between storage systems that support NDMP v4. You can perform both full and incremental data transfers. You can transfer full or partial volumes, qtrees, directories, or individual files.

About this task

Using ONTAP 8.x and earlier releases, incremental transfers are limited to a maximum of two levels (one full and up to two incremental backups).

Beginning with ONTAP 9.0 and later releases, incremental transfers are limited to a maximum of nine levels (one full and up to nine incremental backups).

You can run `ndmpcopy` at the nodeshell command line of the source and destination storage systems, or a storage system that is neither the source nor the destination of the data transfer. You can also run `ndmpcopy` on a single storage system that is both the source and the destination of the data transfer.

You can use IPv4 or IPv6 addresses of the source and destination storage systems in the `ndmpcopy` command. The path format is `/vserver_name/volume_name \[path\]`.

Steps

1. Enable NDMP service on the source and destination storage systems:

If you are performing data transfer at the source or destination in...	Use the following command...
SVM-scoped NDMP mode	<code>vserver services ndmp on</code>  For NDMP authentication in the admin SVM, the user account is <code>admin</code> and the user role is <code>admin</code> or <code>backup</code> . In the data SVM, the user account is <code>vsadmin</code> and the user role is <code>vsadmin</code> or <code>vsadmin-backup</code> role.
Node-scoped NDMP mode	<code>system services ndmp on</code>

2. Transfer data within a storage system or between storage systems using the `ndmpcopy` command at

the nodeshell:

```
::> system node run -node <node_name> < ndmpcopy [options]
source_IP:source_path destination_IP:destination_path [-mcs {inet|inet6}]
[-mcd {inet|inet6}] [-md {inet|inet6}]
```

DNS names are not supported in `ndmpcopy`. You must provide the IP address of the source and the destination. The loopback address (127.0.0.1) is not supported for the source IP address or the destination IP address.

- The `ndmpcopy` command determines the address mode for control connections as follows:
 - The address mode for control connection corresponds to the IP address provided.
 - You can override these rules by using the `-mcs` and `-mcd` options.
- If the source or the destination is the ONTAP system, then depending on the NDMP mode (node-scoped or SVM-scoped), use an IP address that allows access to the target volume.
- `source_path` and `destination_path` are the absolute path names till the granular level of volume, qtree, directory or file.
- `-mcs` specifies the preferred addressing mode for the control connection to the source storage system.

`inet` indicates an IPv4 address mode and `inet6` indicates an IPv6 address mode.

- `-mcd` specifies the preferred addressing mode for the control connection to the destination storage system.

`inet` indicates an IPv4 address mode and `inet6` indicates an IPv6 address mode.

- `-md` specifies the preferred addressing mode for data transfers between the source and the destination storage systems.

`inet` indicates an IPv4 address mode and `inet6` indicates an IPv6 address mode.

If you do not use the `-md` option in the `ndmpcopy` command, the addressing mode for the data connection is determined as follows:

- If either of the addresses specified for the control connections is an IPv6 address, the address mode for the data connection is IPv6.
- If both the addresses specified for the control connections are IPv4 addresses, the `ndmpcopy` command first attempts an IPv6 address mode for the data connection.

If that fails, the command uses an IPv4 address mode.

An IPv6 address, if specified, must be enclosed within square brackets.

This sample command migrates data from a source path (`source_path`) to a destination path (`destination_path`).

```
> ndmpcopy -sa admin:<ndmp_password> -da admin:<ndmp_password>
-st md5 -dt md5 192.0.2.129:/<src_svm>/<src_vol>
192.0.2.131:/<dst_svm>/<dst_vol>
```

This sample command explicitly sets the control connections and the data connection to use IPv6 address mode:

```
> ndmpcopy -sa admin:<ndmp_password> -da admin:<ndmp_password>
-st md5 -dt md5 -mcs inet6 -mcd inet6 -md
inet6 [2001:0db8:1:1:209:6bff:feae:6d67]:/<src_svm>/<src_vol>
[2001:0ec9:1:1:200:7cgg:gfdf:7e78]:/<dst_svm>/<dst_vol>
```

= Options for the `ndmpcopy` command

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

You should understand the options available for the `ndmpcopy` nodeshell command to successfully transfer data.

The following table lists the available options. For more information, see the `ndmpcopy` man pages available through the nodeshell.

Option	Description
<code>-sa username:[password]</code>	<p>This option sets the source authentication user name and password for connecting to the source storage system. This is a mandatory option.</p> <p>For a user without admin privilege, you must specify the user's system-generated NDMP-specific password. The system-generated password is mandatory for both admin and non-admin users.</p>
<code>-da username:[password]</code>	<p>This option sets the destination authentication user name and password for connecting to the destination storage system. This is a mandatory option.</p>
<code>-st {md5 text}</code>	<p>This option sets the source authentication type to be used when connecting to the source storage system. This is a mandatory option and therefore the user should provide either the <code>text</code> or <code>md5</code> option.</p>

Option	Description
-dt {md5 text}	This option sets the destination authentication type to be used when connecting to the destination storage system.
-l	This option sets the dump level used for the transfer to the specified value of level. Valid values are 0, 1, to 9, where 0 indicates a full transfer and 1 to 9 specifies an incremental transfer. The default is 0.
-d	This option enables generation of ndmpcopy debug log messages. The ndmpcopy debug log files are located in the /mroot/etc/log root volume. The ndmpcopy debug log file names are in the ndmpcopy.yyyymmdd format.
-f	This option enables the forced mode. This mode enables system files to be overwritten in the /etc directory on the root of the 7-Mode volume.
-h	This option prints the help message.
-p	<p>This option prompts you to enter the password for source and destination authorization. This password overrides the password specified for -sa and -da options.</p> <div style="border-left: 1px solid #ccc; padding-left: 10px;">  You can use this option only when the command is running in an interactive console. </div>
-exclude	This option excludes specified files or directories from the path specified for data transfer. The value can be a comma-separated list of directory or file names such as .pst or .txt.

= NDMP for FlexVol volumes

= About NDMP for FlexVol volumes

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

The Network Data Management Protocol (NDMP) is a standardized protocol for controlling backup, recovery, and other types of data transfer between primary and secondary storage devices, such as storage systems and tape libraries.

By enabling NDMP support on a storage system, you enable that storage system to communicate with NDMP-enabled network-attached backup applications (also called *Data Management Applications* or *DMA*s), data servers, and tape servers participating in backup or recovery operations. All network communications occur over TCPIP or TCP/IPv6 network. NDMP also provides low-level control of tape drives and medium changers.

You can perform tape backup and restore operations in either node-scoped NDMP mode or storage virtual machine (SVM) scoped NDMP mode.

You must be aware of the considerations that you have to take into account while using NDMP, list of environment variables, and supported NDMP tape backup topologies. You can also enable or disable the enhanced DAR functionality. The two authentication methods supported by ONTAP for authenticating NDMP access to a storage system are: plaintext and challenge.

Related information

[Environment variables supported by ONTAP](#)

= About NDMP modes of operation

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can choose to perform tape backup and restore operations either at the node level as you have been doing until now or at the storage virtual machine (SVM) level. To perform these operations successfully at the SVM level, NDMP service must be enabled on the SVM.

If you upgrade from Data ONTAP 8.2 to Data ONTAP 8.3, the NDMP mode of operation used in 8.2 will continue to be retained post the upgrade from 8.2 to 8.3.

If you install a new cluster with Data ONTAP 8.2 or later, NDMP is in the SVM-scoped NDMP mode by default. To perform tape backup and restore operations in the node-scoped NDMP mode, you must explicitly enable the node-scoped NDMP mode.

Related information

[Commands for managing node-scoped NDMP mode](#)

[Managing node-scoped NDMP mode for FlexVol volumes](#)

[Managing SVM-scoped NDMP mode for FlexVol volumes](#)

= What node-scoped NDMP mode is

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

In the node-scoped NDMP mode, you can perform tape backup and restore operations at the node level. The NDMP mode of operation used in Data ONTAP 8.2 will continue to be retained post the upgrade from 8.2 to 8.3.

In the node-scoped NDMP mode, you can perform tape backup and restore operations on a node that owns the volume. To perform these operations, you must establish NDMP control connections on a LIF hosted on the node that owns the volume or tape devices.

This mode is deprecated and will be removed in a future major release.

Related information

[Managing node-scoped NDMP mode for FlexVol volumes](#)

= What SVM-scoped NDMP mode is

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can perform tape backup and restore operations at the storage virtual machine (SVM) level successfully if the NDMP service is enabled on the SVM. You can back up and restore all volumes hosted across different nodes in the SVM of a cluster if the backup application supports the CAB extension.

An NDMP control connection can be established on different LIF types. In the SVM-scoped NDMP mode, these LIFs belong to either the data SVM or admin SVM. The connection can be established on a LIF only if the NDMP service is enabled on the SVM that owns this LIF.

A data LIF belongs to the data SVM and the intercluster LIF, node-management LIF, and cluster-management LIF belong to the admin SVM.

In the SVM-scoped NDMP mode, the availability of volumes and tape devices for backup and restore operations depends on the LIF type on which the NDMP control connection is established and the status of the CAB extension. If your backup application supports the CAB extension and a volume and the tape device share the same affinity, then the backup application can perform a local backup or restore operation, instead of a three-way backup or restore operation.

Related information

[Managing SVM-scoped NDMP mode for FlexVol volumes](#)

= Considerations when using NDMP

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You must take into account a number of considerations when starting the NDMP service on your storage system.

- Each node supports a maximum of 16 concurrent backups, restores, or combination of the two using connected tape drives.
- NDMP services can generate file history data at the request of NDMP backup applications.

File history is used by backup applications to enable optimized recovery of selected subsets of data from a backup image. File history generation and processing might be time-consuming and CPU-intensive for both the storage system and the backup application.

SMTape does not support file history.

If your data protection is configured for disaster recovery—where the entire backup image will be recovered—you can disable file history generation to reduce backup time. See your backup

application documentation to determine whether it is possible to disable NDMP file history generation.

- Firewall policy for NDMP is enabled by default on all LIF types.
- In node-scoped NDMP mode, backing up a FlexVol volume requires that you use the backup application to initiate a backup on a node that owns the volume.

However, you cannot back up a node root volume.

- You can perform NDMP backup from any LIF as permitted by the firewall policies.

If you use a data LIF, you must select a LIF that is not configured for failover. If a data LIF fails over during an NDMP operation, the NDMP operation fails and must be run again.

- In node-scoped NDMP mode and storage virtual machine (SVM) scoped NDMP mode with no CAB extension support, the NDMP data connection uses the same LIF as the NDMP control connection.
- During LIF migration, ongoing backup and restore operations are disrupted.

You must initiate the backup and restore operations after the LIF migration.

- The NDMP backup path is of the format `/vserver_name/volume_name/path_name`.
path_name is optional, and specifies the path of the directory, file, or Snapshot copy.
- When a SnapMirror destination is backed up to tape by using the dump engine, only the data in the volume is backed up.

However, if a SnapMirror destination is backed up to tape using SMTape, then the metadata is also backed up. The SnapMirror relationships and the associated metadata are not backed up to tape. Therefore, during restore, only the data on that volume is restored, but the associated SnapMirror relationships are not restored.

[ONTAP concepts](#)

[System administration](#)

= Environment variable

= Environment variables overview

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Environment variables are used to communicate information about a backup or restore operation between an NDMP-enabled backup application and a storage system.

For example, if a user specifies that a backup application should back up `/vserver1/vol1/dir1`, the backup application sets the FILESYSTEM environment variable to `/vserver1/vol1/dir1`. Similarly, if a user specifies that a backup should be a level 1 backup, the backup application sets the LEVEL environment variable to 1 (one).

The setting and examining of environment variables are typically transparent to backup administrators; that is, the backup application sets them automatically.

A backup administrator rarely specifies environment variables; however, you might want to change the value of an environment variable from that set by the backup application to characterize or work around a functional or performance problem. For example, an administrator might want to temporarily disable file history generation to determine if the backup application's processing of file history information is contributing to performance issues or functional problems.

Many backup applications provide a means to override or modify environment variables or to specify additional environment variables. For information, see your backup application documentation.

= Environment variables supported by ONTAP

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

Environment variables are used to communicate information about a backup or restore operation between an NDMP-enabled backup application and a storage system. ONTAP supports environment variables, which have an associated default value. However, you can manually modify these default values.

If you manually modify the values set by the backup application, the application might behave unpredictably. This is because the backup or restore operations might not be doing what the backup application expected them to do. But in some cases, judicious modification might help in identifying or working around problems.

The following tables list the environment variables whose behavior is common to dump and SMTape and those variables that are supported only for dump and SMTape. These tables also contain descriptions of how the environment variables that are supported by ONTAP work if they are used:

In most cases, variables that have the value, Y also accept T and N also accept F.

== Environment variables supported for dump and SMTape

Environment variable	Valid values	Default	Description
DEBUG	Y or N	N	Specifies that debugging information is printed.
FILESYSTEM	string	none	Specifies the path name of the root of the data that is being backed up.

Environment variable	Valid values	Default	Description
NDMP_VERSION	return_only	none	<p>You should not modify the NDMP_VERSION variable. Created by the backup operation, the NDMP_VERSION variable returns the NDMP version.</p> <p>ONTAP sets the NDMP_VERSION variable during a backup for internal use and to pass to a backup application for informational purposes. The NDMP version of an NDMP session is not set with this variable.</p>
PATHNAME_SEPARATOR	return_value	none	<p>Specifies the path name separator character.</p> <p>This character depends on the file system being backed up. For ONTAP, the character "/" is assigned to this variable. The NDMP server sets this variable before starting a tape backup operation.</p>
TYPE	dump or smtape	dump	Specifies the type of backup supported to perform tape backup and restore operations.
VERBOSE	Y or N	N	Increases the log messages while performing a tape backup or restore operation.

== Environment variables supported for dump

Environment variable	Valid values	Default	Description
ACL_START	return_only	none	<p>Created by the backup operation, the ACL_START variable is an offset value used by a direct access restore or restartable NDMP backup operation.</p> <p>The offset value is the byte offset in the dump file where the ACL data (Pass V) begins and is returned at the end of a backup. For a direct access restore operation to correctly restore backed-up data, the ACL_START value must be passed to the restore operation when it begins. An NDMP restartable backup operation uses the ACL_START value to communicate to the backup application where the nonrestartable portion of the backup stream begins.</p>
BASE_DATE	0, -1, or DUMP_DATE value	-1	<p>Specifies the start date for incremental backups.</p> <p>When set to -1, the BASE_DATE incremental specifier is disabled. When set to 0 on a level 0 backup, incremental backups are enabled. After the initial backup, the value of the DUMP_DATE variable from the previous incremental backup is assigned to the BASE_DATE variable.</p> <p>These variables are an alternative to the LEVEL/UPDATE based incremental backups.</p>

Environment variable	Valid values	Default	Description
DIRECT	Y or N	N	<p>Specifies that a restore should fast-forward directly to the location on the tape where the file data resides instead of scanning the entire tape.</p> <p>For direct access recovery to work, the backup application must provide positioning information. If this variable is set to Y, the backup application specifies the file or directory names and the positioning information.</p>
DMP_NAME	string	none	<p>Specifies the name for a multiple subtree backup.</p> <p>This variable is mandatory for multiple subtree backups.</p>
DUMP_DATE	return_value	none	<p>You do not change this variable directly. It is created by the backup if the BASE_DATE variable is set to a value other than -1.</p> <p>The DUMP_DATE variable is derived by prepending the 32-bit level value to a 32-bit time value computed by the dump software. The level is incremented from the last level value passed into the BASE_DATE variable. The resulting value is used as the BASE_DATE value on a subsequent incremental backup.</p>

Environment variable	Valid values	Default	Description
ENHANCED_DAR_ENA BLED	Y or N	N	<p>Specifies whether enhanced DAR functionality is enabled. Enhanced DAR functionality supports directory DAR and DAR of files with NT Streams. It provides performance improvements.</p> <p>Enhanced DAR during restore is possible only if the following conditions are met:</p> <ul style="list-style-type: none"> • ONTAP supports enhanced DAR. • File history is enabled (HIST=Y) during the backup. • The <code>ndmpd.offset_map.enable</code> option is set to on. • ENHANCED_DAR_ENABLED variable is set to Y during restore.

Environment variable	Valid values	Default	Description
EXCLUDE	pattern_string	none	<p>Specifies files or directories that are excluded when backing up data.</p> <p>The exclude list is a comma-separated list of file or directory names. If the name of a file or directory matches one of the names in the list, it is excluded from the backup.</p> <p>The following rules apply while specifying names in the exclude list:</p> <ul style="list-style-type: none"> • The exact name of the file or directory must be used. • The asterisk (*), a wildcard character, must be either the first or the last character of the string. <p>Each string can have up to two asterisks.</p> <ul style="list-style-type: none"> • A comma in a file or directory name must be preceded with a backslash. • The exclude list can contain up to 32 names. <p> Files or directories specified to be excluded for backup are not excluded if you set NON_QUOTA_TRE to Y simultaneously.</p>

Environment variable	Valid values	Default	Description
EXTRACT	Y, N, or E	N	<p>Specifies that subtrees of a backed-up data set are to be restored.</p> <p>The backup application specifies the names of the subtrees to be extracted. If a file specified matches a directory whose contents were backed up, the directory is recursively extracted.</p> <p>To rename a file, directory, or qtree during restore without using DAR, you must set the EXTRACT environment variable to E.</p>
EXTRACT_ACL	Y or N	Y	<p>Specifies that ACLs from the backed up file are restored on a restore operation.</p> <p>The default is to restore ACLs when restoring data, except for DARs (DIRECT=Y).</p>

Environment variable	Valid values	Default	Description
FORCE	Y or N	N	<p>Determines if the restore operation must check for volume space and inode availability on the destination volume.</p> <p>Setting this variable to Y causes the restore operation to skip checks for volume space and inode availability on the destination path.</p> <p>If enough volume space or inodes are not available on the destination volume, the restore operation recovers as much data allowed by the destination volume space and inode availability. The restore operation stops when volume space or inodes are not available.</p>

Environment variable	Valid values	Default	Description
HIST	Y or N	N	<p>Specifies that file history information is sent to the backup application.</p> <p>Most commercial backup applications set the HIST variable to Y. If you want to increase the speed of a backup operation, or you want to troubleshoot a problem with the file history collection, you can set this variable to N.</p> <p> You should not set the HIST variable to Y if the backup application does not support file history.</p>

Environment variable	Valid values	Default	Description
IGNORE_CTIME	Y or N	N	<p>Specifies that a file is not incrementally backed up if only its ctime value has changed since the previous incremental backup.</p> <p>Some applications, such as virus scanning software, change the ctime value of a file within the inode, even though the file or its attributes have not changed. As a result, an incremental backup might back up files that have not changed. The IGNORE_CTIME variable should be specified only if incremental backups are taking an unacceptable amount of time or space because the ctime value was modified.</p> <p>The NDMP dump command sets IGNORE_CTIME to false by default. Setting it to true can result in the following data loss:</p>  <ul style="list-style-type: none"> 1. If IGNORE_CTIME is set to true with a volume level incremental ndmp copy,

Environment variable	Valid values	Default	Description
IGNORE_QTREES	Y or N	N	Specifies that the restore operation does not restore qtree information from backed-up qtrees.
LEVEL	0-31	0	<p>Specifies the backup level.</p> <p>Level 0 copies the entire data set. Incremental backup levels, specified by values above 0, copy all files (new or modified) since the last incremental backup. For example, a level 1 backs up new or modified files since the level 0 backup, a level 2 backs up new or modified files since the level 1 backup, and so on.</p>
LIST	Y or N	N	Lists the backed-up file names and inode numbers without actually restoring the data.
LIST_QTREES	Y or N	N	Lists the backed-up qtrees without actually restoring the data.

Environment variable	Valid values	Default	Description
MULTI_SUBTREE_NAMES	string	none	<p>Specifies that the backup is a multiple subtree backup.</p> <p>Multiple subtrees are specified in the string, which is a newline-separated, null-terminated list of subtree names. Subtrees are specified by path names relative to their common root directory, which must be specified as the last element of the list.</p> <p>If you use this variable, you must also use the DMP_NAME variable.</p>
NDMP_UNICODE_FH	Y or N	N	<p>Specifies that a Unicode name is included in addition to the NFS name of the file in the file history information.</p> <p>This option is not used by most backup applications and should not be set unless the backup application is designed to receive these additional file names. The HIST variable must also be set.</p>
NO_ACLS	Y or N	N	Specifies that ACLs must not be copied when backing up data.

Environment variable	Valid values	Default	Description
NON_QUOTA_TREE	Y or N	N	<p>Specifies that files and directories in qtrees must be ignored when backing up data.</p> <p>When set to Y, items in qtrees in the data set specified by the FILESYSTEM variable are not backed up. This variable has an effect only if the FILESYSTEM variable specifies an entire volume. The NON_QUOTA_TREE variable only works on a level 0 backup and does not work if the MULTI_SUBTREE NAMES variable is specified.</p> <p> Files or directories specified to be excluded for backup are not excluded if you set NON_QUOTA_TREE to Y simultaneously.</p>
NOWRITE	Y or N	N	<p>Specifies that the restore operation must not write data to the disk.</p> <p>This variable is used for debugging.</p>

Environment variable	Valid values	Default	Description
RECURSIVE	Y or N	Y	<p>Specifies that directory entries during a DAR restore be expanded.</p> <p>The DIRECT and ENHANCED_DAR_ENABLED environment variables must be enabled (set to Y) as well. If the RECURSIVE variable is disabled (set to N), only the permissions and ACLs for all the directories in the original source path are restored from tape, not the contents of the directories. If the RECURSIVE variable is set to N or the RECOVER_FULL_PATHS variable is set to Y, the recovery path must end with the original path.</p> <p>If the RECURSIVE variable is disabled and if there is more than one recovery path, all of the recovery paths must be contained within the longest of the recovery paths. Otherwise, an error message is displayed.</p> <p>(i)</p> <p>For example, the following are valid recovery paths because</p>

Environment variable	Valid values	Default	Description
RECOVER_FULL_PATH_HS	Y or N	N	<p>Specifies that the full recovery path will have their permissions and ACLs restored after the DAR.</p> <p>DIRECT and ENHANCED_DAR_ENABLED must be enabled (set to Y) as well. If RECOVER_FULL_PATH_HS is set to Y, the recovery path must end with the original path. If directories already exist on the destination volume, their permissions and ACLs will not be restored from tape.</p>
UPDATE	Y or N	Y	Updates the metadata information to enable LEVEL based incremental backup.

== Environment variables supported for SMTape

Environment variable	Valid values	Default	Description
BASE_DATE	DUMP_DATE	-1	<p>Specifies the start date for incremental backups.</p> <p>BASE_DATE is a string representation of the reference Snapshot identifiers. Using the BASE_DATE string, SMTape locates the reference Snapshot copy.</p> <p>BASE_DATE is not required for baseline backups. For an incremental backup, the value of the DUMP_DATE variable from the previous baseline or incremental backup is assigned to the BASE_DATE variable.</p> <p>The backup application assigns the DUMP_DATE value from a previous SMTape baseline or incremental backup.</p>
DUMP_DATE	return_value	none	<p>At the end of an SMTape backup, DUMP_DATE contains a string identifier that identifies the Snapshot copy used for that backup. This Snapshot copy could be used as the reference Snapshot copy for a subsequent incremental backup.</p> <p>The resulting value of DUMP_DATE is used as the BASE_DATE value for subsequent incremental backups.</p>

Environment variable	Valid values	Default	Description
SMTAPE_BACKUP_SET_ID	string	none	<p>Identifies the sequence of incremental backups associated with the baseline backup.</p> <p>Backup set ID is a 128-bit unique ID that is generated during a baseline backup. The backup application assigns this ID as the input to the SMTAPE_BACKUP_SET_ID variable during an incremental backup.</p>
SMTAPE_SNAPSHOT_NAME	Any valid Snapshot copy that is available in the volume	Invalid	<p>When the SMTAPE_SNAPSHOT_NAME variable is set to a Snapshot copy, that Snapshot copy and its older Snapshot copies are backed up to tape.</p> <p>For incremental backup, this variable specifies incremental Snapshot copy. The BASE_DATE variable provides the baseline Snapshot copy.</p>
SMTAPE_DELETE_SNAPSHOT	Y or N	N	For a Snapshot copy created automatically by SMTape, when the SMTAPE_DELETE_SNAPSHOT variable is set to Y, then after the backup operation is complete, SMTape deletes this Snapshot copy. However, a Snapshot copy created by the backup application will not be deleted.

Environment variable	Valid values	Default	Description
SMTAPE_BREAK_MIR ROR	Y or N	N	When the SMTAPE_BREAK_MIR ROR variable is set to Y, the volume of type DP is changed to a RW volume after a successful restore.

= Common NDMP tape backup topologies

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

NDMP supports a number of topologies and configurations between backup applications and storage systems or other NDMP servers providing data (file systems) and tape services.

== Storage system-to-local-tape

In the simplest configuration, a backup application backs up data from a storage system to a tape subsystem attached to the storage system. The NDMP control connection exists across the network boundary. The NDMP data connection that exists within the storage system between the data and tape services is called an NDMP local configuration.

== Storage system-to-tape attached to another storage system

A backup application can also back up data from a storage system to a tape library (a medium changer with one or more tape drives) attached to another storage system. In this case, the NDMP data connection between the data and tape services is provided by a TCP or TCP/IPv6 network connection. This is called an NDMP three-way storage system-to-storage system configuration.

== Storage system-to-network-attached tape library

NDMP-enabled tape libraries provide a variation of the three-way configuration. In this case, the tape library attaches directly to the TCP/IP network and communicates with the backup application and the storage system through an internal NDMP server.

== Storage system-to-data server-to-tape or data server-to-storage system-to-tape

NDMP also supports storage system-to-data-server and data-server-to-storage system three-way configurations, although these variants are less widely deployed. Storage system-to-server allows storage system data to be backed up to a tape library attached to the backup application host or to another data server system. The server-to-storage system configuration allows server data to be backed up to a storage system-attached tape library.

= Supported NDMP authentication methods

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can specify an authentication method to allow NDMP connection requests.

ONTAP supports two methods for authenticating NDMP access to a storage system: plaintext and challenge.

In node-scoped NDMP mode, both challenge and plaintext are enabled by default. However, you cannot disable challenge. You can enable and disable plaintext. In the plaintext authentication method, the login password is transmitted as clear text.

In the storage virtual machine (SVM)-scoped NDMP mode, by default the authentication method is challenge. Unlike the node-scoped NDMP mode, in this mode you can enable and disable both plaintext and challenge authentication methods.

[User authentication in a node-scoped NDMP mode](#)

[User authentication in the SVM-scoped NDMP mode](#)

= NDMP extensions supported by ONTAP

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

NDMP v4 provides a mechanism for creating NDMP v4 protocol extensions without modifying the core NDMP v4 protocol. You should be aware of the NDMP v4 extensions that are supported by ONTAP.

The following NDMP v4 extensions are supported by ONTAP:

- Cluster Aware Backup (CAB)

This extension is supported only in the SVM-scoped NDMP mode.

- Connection Address Extension (CAE) for IPv6 support
- Extension class 0x2050

This extension supports restartable backup operations and Snapshot Management Extensions.

The NDMP_SNAP_RECOVER message, which is part of the Snapshot Management Extensions, is used to initiate a recovery operation and to transfer the recovered data from a local Snapshot copy to a local file system location. In ONTAP, this message allows the recovery of volumes and regular files only.

The NDMP_SNAP_DIR_LIST message enables you to browse through the Snapshot copies of a volume. If a nondisruptive operation takes place while a browsing operation is in progress, the backup application must reinitiate the browsing operation.

= NDMP restartable backup extension for a dump supported by ONTAP

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use the NDMP restartable backup extension (RBE) functionality to restart a

backup from a known checkpoint in the data stream before the failure.

= What enhanced DAR functionality is

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use the enhanced direct access recovery (DAR) functionality for directory DAR and DAR of files and NT streams. By default, enhanced DAR functionality is enabled.

Enabling enhanced DAR functionality might impact the backup performance because an offset map has to be created and written onto tape. You can enable or disable enhanced DAR in both the node-scoped and storage virtual machine (SVM)-scoped NDMP modes.

= Scalability limits for NDMP sessions

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You must be aware of the maximum number of NDMP sessions that can be established simultaneously on storage systems of different system memory capacities. This maximum number depends on the system memory of a storage system.

The limits mentioned in the following table are for the NDMP server. The limits mentioned in the section “Scalability limits for dump backup and restore sessions” are for the dump and restore session.

[Scalability limits for dump backup and restore sessions](#)

System memory of a storage system	Maximum number of NDMP sessions
Less than 16 GB	8
Greater than or equal to 16 GB but less than 24 GB	20
Greater than or equal to 24 GB	36

You can obtain the system memory of your storage system by using the `sysconfig -a` command (available through the nodeshell). For more information about using this command, see the man pages.

= About NDMP for FlexGroup volumes

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Beginning with ONTAP 9.7, NDMP is supported on FlexGroup volumes.

Beginning with ONTAP 9.7, the `ndmpcopy` command is supported for data transfer between FlexVol and FlexGroup volumes.

If you revert from ONTAP 9.7 to an earlier version, the incremental transfer information of the previous transfers is not retained and therefore, you must perform a baseline copy after reverting.

Beginning with ONTAP 9.8, the following NDMP features are supported on FlexGroup volumes:

- The NDMP_SNAP_RECOVER message in the extension class 0x2050 can be used for recovering individual files in a FlexGroup volume.
- NDMP restartable backup extension (RBE) is supported for FlexGroup volumes.
- Environment variables EXCLUDE and MULTI_SUBTREE_NAMES are supported for FlexGroup volumes.

= About NDMP with SnapLock volumes

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Creating multiple copies of regulated data provides you with redundant recovery scenarios, and by using NDMP dump and restore, it's possible to preserve the write once, read many (WORM) characteristics of source files on a SnapLock volume.

WORM attributes on the files in a SnapLock volume are preserved when backing up, restoring and copying data; however, WORM attributes are enforced only when restoring to a SnapLock volume. If a backup from a SnapLock volume is restored to a volume other than a SnapLock volume, the WORM attributes are preserved but are ignored and are not enforced by ONTAP.

= Manage node-scoped NDMP mode for FlexVol volumes

= Manage node-scoped NDMP mode for FlexVol volumes overview

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can manage NDMP at the node level by using NDMP options and commands. You can modify the NDMP options by using the `options` command. You must use NDMP-specific credentials to access a storage system to perform tape backup and restore operations.

For more information about the `options` command, see the man pages.

= Commands for managing node-scoped NDMP mode

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use the `system services ndmp` commands to manage NDMP at a node level. Some of these commands are deprecated and will be removed in a future

major release.

You can use the following NDMP commands only at the advanced privilege level:

- system services ndmp service terminate
- system services ndmp service start
- system services ndmp service stop
- system services ndmp log start
- system services ndmp log stop

If you want to...	Use this command...
Enable NDMP service	system services ndmp on*
Disable NDMP service	system services ndmp off*
Display NDMP configuration	system services ndmp show*
Modify NDMP configuration	system services ndmp modify*
Display the default NDMP version	system services ndmp version*
Display NDMP service configuration	system services ndmp service show
Modify NDMP service configuration	system services ndmp service modify
Display all NDMP sessions	system services ndmp status
Display detailed information about all NDMP sessions	system services ndmp probe
Terminate the specified NDMP session	system services ndmp kill
Terminate all NDMP sessions	system services ndmp kill-all
Change the NDMP password	system services ndmp password*
Enable node-scoped NDMP mode	system services ndmp node-scope-mode on*
Disable node-scoped NDMP mode	system services ndmp node-scope-mode off*

If you want to...	Use this command...
Display the node-scoped NDMP mode status	system services ndmp node-scope-mode status*
Forcefully terminate all NDMP sessions	system services ndmp service terminate
Start the NDMP service daemon	system services ndmp service start
Stop the NDMP service daemon	system services ndmp service stop
Start logging for the specified NDMP session	system services ndmp log start*
Stop logging for the specified NDMP session	system services ndmp log stop*

- These commands are deprecated and will be removed in a future major release.

For more information about these commands, see the man pages for the `system services ndmp` commands.

= User authentication in a node-scoped NDMP mode

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

In the node-scoped NDMP mode, you must use NDMP specific credentials to access a storage system in order to perform tape backup and restore operations.

The default user ID is “root”. Before using NDMP on a node, you must ensure that you change the default NDMP password associated with the NDMP user. You can also change the default NDMP user ID.

= Manage SVM-scoped NDMP mode for FlexVol volumes overview

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can manage NDMP on a per SVM basis by using the NDMP options and commands. You can modify the NDMP options by using the `vserver services ndmp modify` command. In the SVM-scoped NDMP mode, user authentication is integrated with the role-based access control mechanism.

You can add NDMP in the allowed or disallowed protocols list by using the `vserver modify` command. By default, NDMP is in the allowed protocols list. If NDMP is added to the disallowed protocols list, NDMP sessions cannot be established.

You can control the LIF type on which an NDMP data connection is established by using the `-preferred-interface-role` option. During an NDMP data connection establishment, NDMP chooses an IP address that belongs to the LIF type as specified by this option. If the IP addresses do not belong to any of these LIF types, then the NDMP data connection cannot be established. For more information about the `-preferred-interface-role` option, see the man pages.

For more information about the `vserver services ndmp` command, see the man pages.

= What Cluster Aware Backup extension does

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

CAB (Cluster Aware Backup) is an NDMP v4 protocol extension. This extension enables the NDMP server to establish a data connection on a node that owns a volume. This also enables the backup application to determine if volumes and tape devices are located on the same node in a cluster.

To enable the NDMP server to identify the node that owns a volume and to establish a data connection on such a node, the backup application must support the CAB extension. CAB extension requires the backup application to inform the NDMP server about the volume to be backed up or restored prior to establishing

the data connection. This allows the NDMP server to determine the node that hosts the volume and appropriately establish the data connection.

With the CAB extension supported by the backup application, the NDMP server provides affinity information about volumes and tape devices. Using this affinity information, the backup application can perform a local backup instead of a three-way backup if a volume and tape device are located on the same node in a cluster.

= Availability of volumes and tape devices for backup and restore on different LIF types

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can configure a backup application to establish an NDMP control connection on any of the LIF types in a cluster. In the storage virtual machine (SVM)-scoped NDMP mode, you can determine the availability of volumes and tape devices for backup and restore operations depending upon these LIF types and the status of the CAB extension.

The following tables show the availability of volumes and tape devices for NDMP control connection LIF types and the status of the CAB extension:

== Availability of volumes and tape devices when CAB extension is not supported by the backup application

NDMP control connection LIF type	Volumes available for backup or restore	Tape devices available for backup or restore
Node-management LIF	All volumes hosted by a node	Tape devices connected to the node hosting the node-management LIF
Data LIF	Only volumes that belong to the SVM hosted by a node that hosts the data LIF	None
Cluster-management LIF	All volumes hosted by a node that hosts the cluster-management LIF	None
Intercluster LIF	All volumes hosted by a node that hosts the intercluster LIF	Tape devices connected to the node hosting the intercluster LIF

== Availability of volumes and tape devices when CAB extension is supported by the backup application

NDMP control connection LIF type	Volumes available for backup or restore	Tape devices available for backup or restore
Node-management LIF	All volumes hosted by a node	Tape devices connected to the node hosting the node-management LIF

NDMP control connection LIF type	Volumes available for backup or restore	Tape devices available for backup or restore
Data LIF	All volumes that belong to the SVM that hosts the data LIF	None
Cluster-management LIF	All volumes in the cluster	All tape devices in the cluster
Intercluster LIF	All volumes in the cluster	All tape devices in the cluster

= What affinity information is

:icons: font

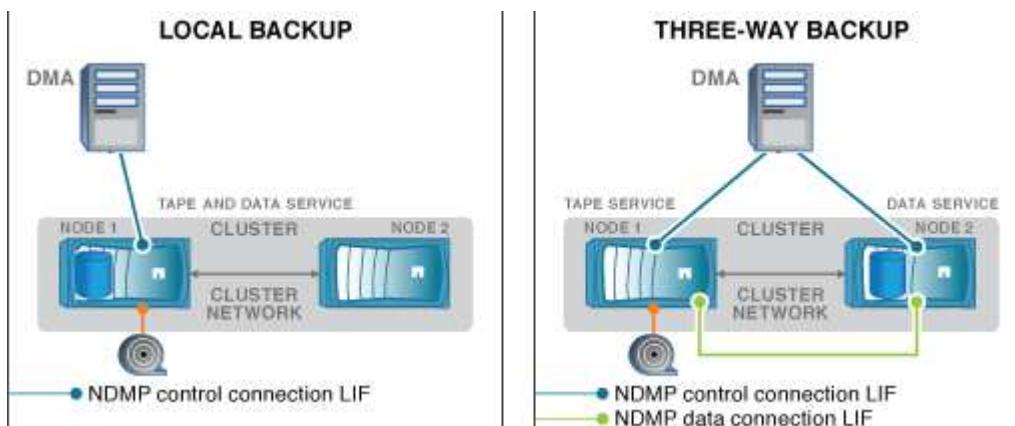

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

With the backup application being CAB aware, the NDMP server provides unique location information about volumes and tape devices. Using this affinity information, the backup application can perform a local backup instead of a three-way backup if a volume and a tape device share the same affinity.

If the NDMP control connection is established on a node management LIF, cluster management LIF, or an intercluster LIF, the backup application can use the affinity information to determine if a volume and tape device are located on the same node and then perform either a local or a three-way backup or restore operation. If the NDMP control connection is established on a data LIF, then the backup application always performs a three-way backup.

-- Local NDMP backup and Three-way NDMP backup

Using the affinity information about volumes and tape devices, the DMA (backup application) performs a local NDMP backup on the volume and tape device located on Node 1 in the cluster. If the volume moves from Node 1 to Node 2, affinity information about the volume and tape device changes. Hence, for a subsequent backup the DMA performs a three-way NDMP backup operation. This ensures continuity of the backup policy for the volume irrespective of the node to which the volume is moved to.

Related information

[What Cluster Aware Backup extension does](#)

= NDMP server supports secure control connections in SVM-scoped mode

```
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

A secure control connection can be established between the Data Management Application (DMA) and NDMP server by using secure sockets (SSL/TLS) as the communication mechanism. This SSL communication is based on the server certificates. The NDMP server listens on port 30000 (assigned by IANA for “ndmps” service).

After establishing the connection from the client on this port, the standard SSL handshake ensues where the server presents the certificate to the client. When the client accepts the certificate, the SSL handshake is complete. After this process is complete, all of the communication between the client and the server is encrypted. The NDMP protocol workflow remains exactly as before. The secure NDMP connection requires server- side certificate authentication only. A DMA can choose to establish a connection either by connecting to the secure NDMP service or the standard NDMP service.

By default, secure NDMP service is disabled for a storage virtual machine (SVM). You can enable or disable the secure NDMP service on a given SVM by using the `vserver services ndmp modify -vserver vserver -is-secure-control-connection-enabled [true|false]` command.

= NDMP data connection types

```
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

In the storage virtual machine (SVM)-scoped NDMP mode, the supported NDMP data connection types depend on the NDMP control connection LIF type and the status of the CAB extension. This NDMP data connection type indicates whether you can perform a local or a three-way NDMP backup or restore operation.

You can perform a three-way NDMP backup or restore operation over a TCP or TCP/IPv6 network. The following tables show the NDMP data connection types based on the NDMP control connection LIF type and the status of the CAB extension.

== NDMP data connection type when CAB extension is supported by the backup application

NDMP control connection LIF type	NDMP data connection type
Node-management LIF	LOCAL, TCP, TCP/IPv6
Data LIF	TCP, TCP/IPv6
Cluster-management LIF	LOCAL, TCP, TCP/IPv6
Intercluster LIF	LOCAL, TCP, TCP/IPv6

== NDMP data connection type when CAB extension is not supported by the backup application

NDMP control connection LIF type	NDMP data connection type
Node-management LIF	LOCAL, TCP, TCP/IPv6
Data LIF	TCP, TCP/IPv6
Cluster-management LIF	TCP, TCP/IPv6
Intercluster LIF	LOCAL, TCP, TCP/IPv6

[Network management](#)

= User authentication in the SVM-scoped NDMP mode

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

In the storage virtual machine (SVM)-scoped NDMP mode, NDMP user authentication is integrated with role-based access control. In the SVM context, the NDMP user must have either the “vsadmin” or “vsadmin-backup” role. In a cluster context, the NDMP user must have either the “admin” or “backup” role.

Apart from these pre-defined roles, a user account associated with a custom role can also be used for NDMP authentication provided that the custom role has the “vserver services ndmp” folder in its command directory and the access level of the folder is not “none”. In this mode, you must generate an NDMP password for a given user account, which is created through role-based access control. Cluster users in an admin or backup role can access a node-management LIF, a cluster-management LIF, or an intercluster LIF. Users in a vsadmin-backup or vsadmin role can access only the data LIF for that SVM. Therefore, depending on the role of a user, the availability of volumes and tape devices for backup and restore operations vary.

This mode also supports user authentication for NIS and LDAP users. Therefore, NIS and LDAP users can access multiple SVMs with a common user ID and password. However, NDMP authentication does not support Active Directory users.

In this mode, a user account must be associated with the SSH application and the “User password” authentication method.

Related information

[Commands for managing SVM-scoped NDMP mode](#)

[ONTAP concepts](#)

= Generate an NDMP-specific password for NDMP users

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

In the storage virtual machine (SVM)-scoped NDMP mode, you must generate a password for a specific user ID. The generated password is based on the actual login password for the NDMP user. If the actual login password changes, you must generate the NDMP-specific password again.

Steps

1. Use the `vserver services ndmp generate-password` command to generate an NDMP-specific password.

You can use this password in any current or future NDMP operation that requires password input.

From the storage virtual machine (SVM, formerly known as Vserver) context, you can generate NDMP passwords for users belonging only to that SVM.

The following example shows how to generate an NDMP-specific password for a user ID user1:

```
cluster1::vserver services ndmp> generate-password -vserver vs1  
-user user1  
  
Vserver: vs1  
User: user1  
Password: jWZint57huPOoD8d
```

2. If you change the password to your regular storage system account, repeat this procedure to obtain your new NDMP-specific password.

= How tape backup and restore operations are affected during disaster recovery in MetroCluster configuration

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

You can perform tape backup and restore operations simultaneously during disaster recovery in a MetroCluster configuration. You must understand how these operations are affected during disaster recovery.

If tape backup and restore operations are performed on a volume of anSVM in a disaster recovery relationship, then you can continue performing incremental tape backup and restore operations after a switchover and switchback.

= About dump engine for FlexVol volumes

= About dump engine for FlexVol volumes

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

Dump is a Snapshot copy based backup and recovery solution from ONTAP that

helps you to back up files and directories from a Snapshot copy to a tape device and restore the backed up data to a storage system.

You can back up your file system data, such as directories, files, and their associated security settings, to a tape device by using the dump backup. You can back up an entire volume, an entire qtree, or a subtree that is neither an entire volume nor an entire qtree.

You can perform a dump backup or restore by using NDMP-compliant backup applications.

When you perform a dump backup, you can specify the Snapshot copy to be used for a backup. If you do not specify a Snapshot copy for the backup, the dump engine creates a Snapshot copy for the backup. After the backup operation is completed, the dump engine deletes this Snapshot copy.

You can perform level-0, incremental, or differential backups to tape by using the dump engine.

After reverting to a release earlier than Data ONTAP 8.3, you must perform a baseline backup operation before performing an incremental backup operation.

Related information

[Upgrade, revert, or downgrade](#)

= How a dump backup works

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

A dump backup writes file system data from disk to tape using a predefined process. You can back up a volume, a qtree, or a subtree that is neither an entire volume nor an entire qtree.

The following table describes the process that ONTAP uses to back up the object indicated by the dump path:

Stage	Action
1	For less than full volume or full qtree backups, ONTAP traverses directories to identify the files to be backed up. If you are backing up an entire volume or qtree, ONTAP combines this stage with Stage 2.
2	For a full volume or full qtree backup, ONTAP identifies the directories in the volumes or qtrees to be backed up.
3	ONTAP writes the directories to tape.
4	ONTAP writes the files to tape.
5	ONTAP writes the ACL information (if applicable) to tape.

The dump backup uses a Snapshot copy of your data for the backup. Therefore, you do not have to take the volume offline before initiating the backup.

The dump backup names each Snapshot copy it creates as `snapshot_for_backup.n`, where `n` is an integer starting at 0. Each time the dump backup creates a Snapshot copy, it increments the integer by 1. The integer is reset to 0 after the storage system is rebooted. After the backup operation is completed, the dump engine deletes this Snapshot copy.

When ONTAP performs multiple dump backups simultaneously, the dump engine creates multiple Snapshot copies. For example, if ONTAP is running two dump backups simultaneously, you find the following Snapshot copies in the volumes from which data is being backed up:

`snapshot_for_backup.0` and `snapshot_for_backup.1`.

When you are backing up from a Snapshot copy, the dump engine does not create an additional Snapshot copy.

= Types of data that the dump engine backs up

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

The dump engine enables you to back up data to tape to guard against disasters or controller disruptions. In addition to backing up data objects such as files, directories, qtrees, or entire volumes, the dump engine can back up many types of information about each file. Knowing the types of data that the dump engine can back up and the restrictions to take into consideration can help you plan your approach to disaster recovery.

In addition to backing up data in files, the dump engine can back up the following information about each file, as applicable:

- UNIX GID, owner UID, and file permissions
- UNIX access, creation, and modification time
- File type
- File size
- DOS name, DOS attributes, and creation time
- Access control lists (ACLs) with 1,024 access control entries (ACEs)
- Qtree information
- Junction paths

Junction paths are backed up as symbolic links.

- LUN and LUN clones

You can back up an entire LUN object; however, you cannot back up a single file within the LUN object. Similarly, you can restore an entire LUN object but not a single file within the LUN.

The dump engine backs up LUN clones as independent LUNs.

- VM-aligned files

Backup of VM-aligned files is not supported in releases earlier than Data ONTAP 8.1.2.

When a snapshot-backed LUN clone is transitioned from Data ONTAP operating in 7-Mode to ONTAP, it becomes an inconsistent LUN. The dump engine does not back up inconsistent LUNs.

When you restore data to a volume, client I/O is restricted on the LUNs being restored. The LUN restriction is removed only when the dump restore operation is complete. Similarly, during a SnapMirror single file or LUN restore operation, client I/O is restricted on both files and LUNs being restored. This restriction is removed only when the single file or LUN restore operation is complete. If a dump backup is performed on a volume on which a dump restore or SnapMirror single file or LUN restore operation is being performed, then the files or LUNs that have client I/O restriction are not included in the backup. These files or LUNs are included in a subsequent backup operation if the client I/O restriction is removed.

A LUN running on Data ONTAP 8.3 that is backed up to tape can be restored only to 8.3 and later releases and not to an earlier release. If the LUN is restored to an earlier release, then the LUN is restored as a file.

When you back up a SnapVault secondary volume or a volume SnapMirror destination to tape, only the data on the volume is backed up. The associated metadata is not backed up. Therefore, when you try to restore the volume, only the data on that volume is restored. Information about the volume SnapMirror relationships is not available in the backup and therefore is not restored.

If you dump a file that has only Windows NT permissions and restore it to a UNIX-style qtree or volume, the file gets the default UNIX permissions for that qtree or volume.

If you dump a file that has only UNIX permissions and restore it to an NTFS-style qtree or volume, the file gets the default Windows permissions for that qtree or volume.

Other dumps and restores preserve permissions.

You can back up VM-aligned files and the `vm-align-sector` option. For more information about VM-aligned files, see [Logical storage management](#).

= What increment chains are

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

An increment chain is a series of incremental backups of the same path. Because you can specify any level of backup at any time, you must understand increment chains to be able to perform backups and restores effectively. You can perform 31 levels of incremental backup operations.

There are two types of increment chains:

- A consecutive increment chain, which is a sequence of incremental backups that starts with level 0 and is raised by 1 at each subsequent backup.
- A nonconsecutive increment chain, where incremental backups skip levels or have levels that are out of sequence, such as 0, 2, 3, 1, 4, or more commonly 0, 1, 1, 1 or 0, 1, 2, 1, 2.

Incremental backups are based on the most recent lower-level backup. For example, the sequence of backup levels 0, 2, 3, 1, 4 provides two increment chains: 0, 2, 3 and 0, 1, 4. The following table explains the bases of the incremental backups:

Backup order	Increment level	Increment chain	Base	Files backed up
1	0	Both	Files on the storage system	All files in the backup path
2	2	0, 2, 3	Level-0 backup	Files in the backup path created since the level-0 backup
3	3	0, 2, 3	Level-2 backup	Files in the backup path created since the level-2 backup
4	1	0, 1, 4	Level-0 backup, because this is the most recent level that is lower than the level-1 backup	Files in the backup path created since the level-0 backup, including files that are in the level-2 and level-3 backups
5	4	0, 1, 4	The level-1 backup, because it is a lower level and is more recent than the level-0, level-2, or level-3 backups	Files created since the level-1 backup

= What the blocking factor is

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

A tape block is 1,024 bytes of data. During a tape backup or restore, you can specify the number of tape blocks that are transferred in each read/write operation. This number is called the *blocking factor*.

You can use a blocking factor from 4 to 256. If you plan to restore a backup to a system other than the system that did the backup, the restore system must support the blocking factor that you used for the backup. For example, if you use a blocking factor of 128, the system on which you restore that backup must support a blocking factor of 128.

During an NDMP backup, the MOVER_RECORD_SIZE determines the blocking factor. ONTAP allows a maximum value of 256 KB for MOVER_RECORD_SIZE.

= When to restart a dump backup

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

A dump backup sometimes does not finish because of internal or external errors,

such as tape write errors, power outages, accidental user interruptions, or internal inconsistency on the storage system. If your backup fails for one of these reasons, you can restart it.

You can choose to interrupt and restart a backup to avoid periods of heavy traffic on the storage system or to avoid competition for other limited resources on the storage system, such as a tape drive. You can interrupt a long backup and restart it later if a more urgent restore (or backup) requires the same tape drive. Restartable backups persist across reboots. You can restart an aborted backup to tape only if the following conditions are true:

- The aborted backup is in phase IV.
- All of the associated Snapshot copies that were locked by the dump command are available.
- The file history must be enabled.

When such a dump operation is aborted and left in a restartable state, the associated Snapshot copies are locked. These Snapshot copies are released after the backup context is deleted. You can view the list of backup contexts by using the `vserver services ndmp restartable backup show` command.

```

cluster::> vserver services ndmpd restartable-backup show
Vserver      Context Identifier          Is Cleanup Pending?
-----
vserver1 330e6739-0179-11e6-a299-005056bb4bc9 false

cluster::>"
```

= How a dump restore works

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

A dump restore writes file system data from tape to disk using a predefined process.

The process in the following table shows how the dump restore works:

Stage	Action
1	ONTAP catalogs the files that need to be extracted from the tape.
2	ONTAP creates directories and empty files.

Stage	Action
3	ONTAP reads a file from tape, writes it to disk, and sets the permissions (including ACLs) on it.
4	ONTAP repeats stages 2 and 3 until all the specified files are copied from the tape.

= Types of data that the dump engine restores

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest//media/

When a disaster or controller disruption occurs, the dump engine provides multiple methods for you to recover all of the data that you backed up, from single files, to file attributes, to entire directories. Knowing the types of data that dump engine can restore and when to use which method of recovery can help minimize downtime.

You can restore data to an online mapped LUN. However, host applications cannot access this LUN until the restore operation is complete. After the restore operation is complete, the host cache of the LUN data should be flushed to provide coherency with the restored data.

The dump engine can recover the following data:

- Contents of files and directories
- UNIX file permissions
- ACLs

If you restore a file that has only UNIX file permissions to an NTFS qtree or volume, the file has no Windows NT ACLs. The storage system uses only the UNIX file permissions on this file until you create a Windows NT ACL on it.

If you restore ACLs backed up from storage systems running Data ONTAP 8.2 to storage systems running Data ONTAP 8.1.x and earlier that have an ACE limit lower than 1,024, a default ACL is restored.

- Qtree information

Qtree information is used only if a qtree is restored to the root of a volume. Qtree information is not used if a qtree is restored to a lower directory, such as /vs1/vol1/subdir/lowerdir, and it ceases to be a qtree.

- All other file and directory attributes
- Windows NT streams
- LUNs

◦ A LUN must be restored to a volume level or a qtree level for it to remain as a LUN.

If it is restored to a directory, it is restored as a file because it does not contain any valid metadata.

◦ A 7-Mode LUN is restored as a LUN on an ONTAP volume.

- A 7-Mode volume can be restored to an ONTAP volume.
- VM-aligned files restored to a destination volume inherit the VM-align properties of the destination volume.
- The destination volume for a restore operation might have files with mandatory or advisory locks.

While performing restore operation to such a destination volume, the dump engine ignores these locks.

= Considerations before restoring data

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can restore backed-up data to its original path or to a different destination. If you are restoring backed-up data to a different destination, you must prepare the destination for the restore operation.

Before restoring data either to its original path or to a different destination, you must have the following information and meet the following requirements:

- The level of the restore
- The path to which you are restoring the data
- The blocking factor used during the backup
- If you are doing an incremental restore, all tapes must be in the backup chain
- A tape drive that is available and compatible with the tape to be restored from

Before restoring data to a different destination, you must perform the following operations:

- If you are restoring a volume, you must create a new volume.
- If you are restoring a qtree or a directory, you must rename or move files that are likely to have the same names as files you are restoring.

In ONTAP 9, qtree names support the Unicode format. The earlier releases of ONTAP do not support this format. If a qtree with Unicode names in ONTAP 9 is copied to an earlier release of ONTAP using the `ndmpcopy` command or through restoration from a backup image in a tape, the qtree is restored as a regular directory and not as a qtree with Unicode format.

If a restored file has the same name as an existing file, the existing file is overwritten by the restored file. However, the directories are not overwritten.

To rename a file, directory, or qtree during restore without using DAR, you must set the EXTRACT environment variable to E.

== Required space on the destination storage system

You require about 100 MB more space on the destination storage system than the amount of data to be restored.

 The restore operation checks for volume space and inode availability on the destination volume when the restore operation starts. Setting the FORCE environment variable to Y causes the restore operation to skip the checks for volume space and inode availability on the destination path. If there is not enough volume space or inodes available on the destination volume, the restore operation recovers as much data allowed by the destination volume space and inode availability. The restore operation stops when there is no more volume space or inodes left.

= Scalability limits for dump backup and restore sessions

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You must be aware of the maximum number of dump backup and restore sessions that can be performed simultaneously on storage systems of different system memory capacities. This maximum number depends on the system memory of a storage system.

The limits mentioned in the following table are for the dump or restore engine. The limits mentioned in the scalability limits for NDMP sessions are for the NDMP server, which are higher than the engine limits.

System memory of a storage system	Total number of dump backup and restore sessions
Less than 16 GB	4
Greater than or equal to 16 GB but less than 24 GB	16
Greater than or equal to 24 GB	32

If you use `ndmpcopy` command to copy data within storage systems, two NDMP sessions are established, one for dump backup and the other for dump restore.

You can obtain the system memory of your storage system by using the `sysconfig -a` command (available through the nodeshell). For more information about using this command, see the man pages.

[Scalability limits for NDMP sessions](#)

= Tape backup and restore support between Data ONTAP operating in 7-Mode and ONTAP

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can restore data backed up from a storage system operating in 7-Mode or running ONTAP to a storage system either operating in 7-Mode or running ONTAP.

The following tape backup and restore operations are supported between Data ONTAP operating in 7-Mode and ONTAP:

- Backing up a 7-Mode volume to a tape drive connected to a storage system running ONTAP
- Backing up an ONTAP volume to a tape drive connected to a 7-Mode system
- Restoring backed-up data of a 7-Mode volume from a tape drive connected to a storage system running ONTAP
- Restoring backed-up data of an ONTAP volume from a tape drive connected to a 7-Mode system
- Restoring a 7-Mode volume to an ONTAP volume

- A 7-Mode LUN is restored as a LUN on an ONTAP volume.
- You should retain the ONTAP LUN identifiers when restoring a 7-Mode LUN to an existing ONTAP LUN.

- Restoring an ONTAP volume to a 7-Mode volume

An ONTAP LUN is restored as a regular file on a 7-Mode volume.

= Delete restartable contexts

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

If you want to start a backup instead of restarting a context, you can delete the context.

About this task

You can delete a restartable context using the vserver services ndmp restartable-backup delete command by providing the SVM name and the context ID.

Steps

1. Delete a restartable context:

```
vserver services ndmp restartable-backup delete -vserver vserver-name
-context-id context_identifier.
```

```

cluster::> vserver services ndmpd restartable-backup show
Vserver      Context Identifier          Is Cleanup Pending?
-----
vserver1    330e6739-0179-11e6-a299-005056bb4bc9 false
vserver1    481025c1-0179-11e6-a299-005056bb4bc9 false
vserver2    5cf10132-0179-11e6-a299-005056bb4bc9 false
3 entries were displayed.

cluster::>
cluster::> vserver services ndmp restartable-backup delete -vserver
vserver1 -context-id 481025c1-0179-11e6-a299-005056bb4bc9

cluster::> vserver services ndmpd restartable-backup show
Vserver      Context Identifier          Is Cleanup Pending?
-----
vserver1    330e6739-0179-11e6-a299-005056bb4bc9 false

3 entries were displayed.

cluster::>"
```

= How dump works on a SnapVault secondary volume

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can perform tape backup operations on data that is mirrored on the SnapVault secondary volume. You can back up only the data that is mirrored on the SnapVault secondary volume to tape, and not the SnapVault relationship metadata.

When you break the data protection mirror relationship (`snapmirror break`) or when a SnapMirror resynchronization occurs, you must always perform a baseline backup.

= How dump works with storage failover and ARL operations

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Before you perform dump backup or restore operations, you should understand how these operations work with storage failover (takeover and giveback) or aggregate relocation (ARL) operations. The `-override-veto`s option determines the behavior of dump engine during a storage failover or ARL operation.

When a dump backup or restore operation is running and the `-override-veto`s option is set to `false`, a user-initiated storage failover or ARL operation is stopped. However, if the `-override-veto`s option is set to `true`, then the storage failover or ARL operation is continued and the dump backup or restore operation is aborted. When a storage failover or ARL operation is automatically initiated

by the storage system, an active dump backup or restore operation is always aborted. You cannot restart dump backup and restore operations even after storage failover or ARL operations complete.

== Dump operations when CAB extension is supported

If the backup application supports CAB extension, you can continue performing incremental dump backup and restore operations without reconfiguring backup policies after a storage failover or ARL operation.

== Dump operations when CAB extension is not supported

If the backup application does not support CAB extension, you can continue performing incremental dump backup and restore operations if you migrate the LIF configured in the backup policy to the node that hosts the destination aggregate. Otherwise, after the storage failover and ARL operation, you must perform a baseline backup prior to performing the incremental backup operation.

For storage failover operations, the LIF configured in the backup policy must be migrated to the partner node.

[ONTAP concepts](#)

[High Availability](#)

= How dump works with volume move

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..../media/

Tape backup and restore operations and volume move can run in parallel until the final cutover phase is attempted by the storage system. After this phase, new tape backup and restore operations are not allowed on the volume that is being moved. However, the current operations continue to run until completion.

The following table describes the behavior of tape backup and restore operations after the volume move operation:

If you are performing tape backup and restore operations in the...	Then...
storage virtual machine (SVM) scoped NDMP mode when CAB extension is supported by the backup application	You can continue performing incremental tape backup and restore operations on read/write and read-only volumes without reconfiguring backup policies.
SVM-scoped NDMP mode when CAB extension is not supported by the backup application	You can continue performing incremental tape backup and restore operations on read/write and read-only volumes if you migrate the LIF configured in the backup policy to the node that hosts the destination aggregate. Otherwise, after the volume move, you must perform a baseline backup before performing the incremental backup operation.

When a volume move occurs, if the volume belonging to a different SVM on the destination node has the same name as that of the moved volume, then you cannot perform incremental backup operations of the moved volume.

Related information

[ONTAP concepts](#)

= How dump works when a FlexVol volume is full

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Before performing an incremental dump backup operation, you must ensure that there is sufficient free space in the FlexVol volume.

If the operation fails, you must increase the free space in the Flex Vol volume either by increasing its size or by deleting the Snapshot copies. Then perform the incremental backup operation again.

= How dump works when volume access type changes

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

When a SnapMirror destination volume or a SnapVault secondary volume changes state from read/write to read-only or from read-only to read/write, you must perform a baseline tape backup or restore operation.

SnapMirror destination and SnapVault secondary volumes are read-only volumes. If you perform tape backup and restore operations on such volumes, you must perform a baseline backup or restore operation whenever the volume changes state from read-only to read/write or from read/write to read-only.

Related information

[ONTAP concepts](#)

= How dump works with SnapMirror single file or LUN restore

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Before you perform dump backup or restore operations on a volume to which a single file or LUN is restored by using SnapMirror technology, you must understand how dump operations work with a single file or LUN restore operation.

During a SnapMirror single file or LUN restore operation, client I/O is restricted on the file or LUN being restored. When the single file or LUN restore operation finishes, the I/O restriction on the file or LUN is removed. If a dump backup is performed on a volume to which a single file or LUN is restored, then the file or LUN that has client I/O restriction is not included in the dump backup. In a subsequent backup operation, this file or LUN is backed up to tape after the I/O restriction is removed.

You cannot perform a dump restore and a SnapMirror single file or LUN restore operation simultaneously on the same volume.

= How dump backup and restore operations are affected in MetroCluster configurations

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

Before you perform dump backup and restore operations in a MetroCluster configuration, you must understand how dump operations are affected when a switchover or switchback operation occurs.

== Dump backup or restore operation followed by switchover

Consider two clusters: cluster 1 and cluster 2. During a dump backup or restore operation on cluster 1, if a switchover is initiated from cluster 1 to cluster 2, then the following occurs:

- If the value of the `override-vetoes` option is `false`, then the switchover is aborted and the backup or restore operation continues.
- If the value of the option is `true`, then the dump backup or restore operation is aborted and the switchover continues.

== Dump backup or restore operation followed by switchback

A switchover is performed from cluster 1 to cluster 2 and a dump backup or restore operation is initiated on cluster 2. The dump operation backs up or restores a volume that is located on cluster 2. At this point, if a switchback is initiated from cluster 2 to cluster 1, then the following occurs:

- If the value of the `override-vetoes` option is `false`, then the switchback is cancelled and the backup or restore operation continues.
- If the value of the option is `true`, then the backup or restore operation is aborted and the switchback continues.

== Dump backup or restore operation initiated during a switchover or switchback

During a switchover from cluster 1 to cluster 2, if a dump backup or restore operation is initiated on cluster 1, then the backup or restore operation fails and the switchover continues.

During a switchback from cluster 2 to cluster 1, if a dump backup or restore operation is initiated from cluster 2, then the backup or restore operation fails and the switchback continues.

= About SMTape engine for FlexVol volumes

= About SMTape engine for FlexVol volumes

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

SMTape is a disaster recovery solution from ONTAP that backs up blocks of data to tape. You can use SMTape to perform volume backups to tapes. However, you cannot perform a backup at the qtree or subtree level. SMTape supports baseline, differential, and incremental backups. SMTape does not require a license.

You can perform an SMTape backup and restore operation by using an NDMP-compliant backup application. You can choose SMTape to perform backup and restore operations only in the storage virtual

machine (SVM) scoped NDMP mode.

Reversion process is not supported when an SMTape backup or restore session is in progress. You must wait until the session finishes or you must abort the NDMP session.

Using SMTape, you can back up 255 Snapshot copies. For subsequent baseline, incremental, or differential backups, you must delete older backed-up Snapshot copies.

Before performing a baseline restore, the volume to which data is being restored must be of type DP and this volume must be in the restricted state. After a successful restore, this volume is automatically online. You can perform subsequent incremental or differential restores on this volume in the order in which the backups were performed.

= Use Snapshot copies during SMTape backup

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

You should understand how Snapshot copies are used during an SMTape baseline backup and an incremental backup. There are also considerations to keep in mind while performing a backup using SMTape.

== Baseline backup

While performing a baseline backup, you can specify the name of the Snapshot copy to be backed up to tape. If no Snapshot copy is specified, then depending on the access type of the volume (read/write or read-only), either a Snapshot copy is created automatically or existing Snapshot copies are used. When you specify a Snapshot copy for the backup, all the Snapshot copies older than the specified Snapshot copy are also backed up to tape.

If you do not specify a Snapshot copy for the backup, the following occurs:

- For a read/write volume, a Snapshot copy is created automatically.

The newly created Snapshot copy and all the older Snapshot copies are backed up to tape.

- For a read-only volume, all the Snapshot copies, including the latest Snapshot copy, are backed up to tape.

Any new Snapshot copies created after the backup is started are not backed up.

== Incremental backup

For SMTape incremental or differential backup operations, the NDMP-compliant backup applications create and manage the Snapshot copies.

You must always specify a Snapshot copy while performing an incremental backup operation. For a successful incremental backup operation, the Snapshot copy backed up during the previous backup operation (baseline or incremental) must be on the volume from which the backup is performed. To ensure that you use this backed-up Snapshot copy, you must consider the Snapshot policy assigned on this volume while configuring the backup policy.

== Considerations on SMTape backups on SnapMirror destinations

- A data protection mirror relationship creates temporary Snapshot copies on the destination volume for replication.

You should not use these Snapshot copies for SMTape backup.

- If a SnapMirror update occurs on a destination volume in a data protection mirror relationship during an SMTape backup operation on the same volume, then the Snapshot copy that is backed up by SMTape must not be deleted on the source volume.

During the backup operation, SMTape locks the Snapshot copy on the destination volume and if the corresponding Snapshot copy is deleted on the source volume, then the subsequent SnapMirror update operation fails.

- You should not use these Snapshot copies during incremental backup.

= SMTape capabilities

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

SMTape capabilities such as backup of Snapshot copies, incremental and differential backups, preservation of deduplication and compression features on restored volumes, and tape seeding help you optimize your tape backup and restore operations.

SMTape provides the following capabilities:

- Provides a disaster recovery solution
- Enables incremental and differential backups
- Backs up Snapshot copies
- Enables backup and restore of deduplicated volumes and preserves deduplication on the restored volumes
- Backs up compressed volumes and preserves compression on the restored volumes
- Enables tape seeding

SMTape supports the blocking factor in multiples of 4 KB, in the range of 4 KB through 256 KB.

You can restore data to volumes created across up to two major consecutive ONTAP releases only.

= Features not supported in SMTape

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

SMTape does not support restartable backups and verification of backed-up files.

= Scalability limits for SMTape backup and restore sessions

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

While performing SMTape backup and restore operations through NDMP or CLI (tape seeding), you must be aware of the maximum number of SMTape backup and restore sessions that can be performed simultaneously on storage systems with different system memory capacities. This maximum number depends on the system memory of a storage system.

SMTape backup and restore sessions scalability limits are different from NDMP session limits and dump session limits.

System memory of the storage system	Total number of SMTape backup and restore sessions
Less than 16 GB	6
Greater than or equal to 16 GB but less than 24 GB	16
Greater than or equal to 24 GB	32

You can obtain the system memory of your storage system by using the `sysconfig -a` command (available through the nodeshell). For more information about using this command, see the man pages.

= What tape seeding is

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Tape seeding is an SMTape functionality that helps you initialize a destination FlexVol volume in a data protection mirror relationship.

Tape seeding enables you to establish a data protection mirror relationship between a source system and a destination system over a low-bandwidth connection.

Incremental mirroring of Snapshot copies from the source to the destination is feasible over a low bandwidth connection. However, an initial mirroring of the base Snapshot copy takes a long time over a low-bandwidth connection. In such cases, you can perform an SMTape backup of the source volume to a tape and use the tape to transfer the initial base Snapshot copy to the destination. You can then set up incremental SnapMirror updates to the destination system using the low-bandwidth connection.

[ONTAP concepts](#)

= How SMTape works with storage failover and ARL operations

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Before you perform SMTape backup or restore operations, you should understand how these operations work with storage failover (takeover and giveback) or aggregate relocation (ARL) operation. The `-override-veto`s option determines the behavior of SMTape engine during a storage failover or ARL operation.

When an SMTape backup or restore operation is running and the `-override-veto`s option is set to `false`, a user-initiated storage failover or ARL operation is stopped and the backup or restore operation complete. If the backup application supports CAB extension, then you can continue performing incremental SMTape backup and restore operations without reconfiguring backup policies. However, if the `-override-veto`s option is set to `true`, then the storage failover or ARL operation is continued and the SMTape backup or restore operation is aborted.

[Network management](#)

[High Availability](#)

= How SMTape works with volume move

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

SMTape backup operations and volume move operations can run in parallel until the storage system attempts the final cutover phase. After this phase, new SMTape backup operations cannot run on the volume that is being moved. However, the current operations continue to run until completion.

Before the cutover phase for a volume is started, the volume move operation checks for active SMTape backup operations on the same volume. If there are active SMTape backup operations, then the volume move operation moves into a cutover deferred state and allows the SMTape backup operations to complete. After these backup operations are completed, you must manually restart the volume move operation.

If the backup application supports CAB extension, you can continue performing incremental tape backup and restore operations on read/write and read-only volumes without reconfiguring backup policies.

Baseline restore and volume move operations cannot be performed simultaneously; however, incremental restore can run in parallel with volume move operations, with the behavior similar to that of SMTape backup operations during volume move operations.

Related information

[ONTAP concepts](#)

= How SMTape works with volume rehost operations

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

SMTape operations cannot commence when a volume rehost operation is in progress on a volume. When a volume is involved in a volume rehost operation, SMTape sessions should not be started on that volume.

If any volume rehost operation is in progress, then SMTape backup or restore fails. If an SMTape backup or restore is in progress, then volume rehost operations fail with an appropriate error message. This condition applies to both NDMP-based and CLI-based backup or restore operations.

= How NDMP backup policy are affected during ADB

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

When the automatic data balancer (ADB) is enabled, the balancer analyzes the usage statistics of aggregates to identify the aggregate that has exceeded the configured high-threshold usage percentage.

After identifying the aggregate that has exceeded the threshold, the balancer identifies a volume that can be moved to aggregates residing in another node in the cluster and attempts to move that volume. This situation affects the backup policy configured for this volume because if the data management application (DMA) is not CAB aware, then the user has to reconfigure the backup policy and run the baseline backup operation.

If the DMA is CAB aware and the backup policy has been configured using specific interface, then the ADB is not affected.

= How SMTape backup and restore operations are affected in MetroCluster configurations

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Before you perform SMTape backup and restore operations in a MetroCluster configuration, you must understand how SMTape operations are affected when a switchover or switchback operation occurs.

== SMTape backup or restore operation followed by switchover

Consider two clusters: cluster 1 and cluster 2. During an SMTape backup or restore operation on cluster 1, if a switchover is initiated from cluster 1 to cluster 2, then the following occurs:

- If the value of the `-override-veto`s option is `false`, then the switchover process is aborted and the backup or restore operation continues.
- If the value of the option is `true`, then the SMTape backup or restore operation is aborted and the switchover process continues.

== SMTape backup or restore operation followed by switchback

A switchover is performed from cluster 1 to cluster 2 and an SMTape backup or restore operation is initiated on cluster 2. The SMTape operation backs up or restores a volume that is located on cluster 2. At this point, if a switchback is initiated from cluster 2 to cluster 1, then the following occurs:

- If the value of the `-override-veto`s option is `false`, then the switchback process is aborted and the backup or restore operation continues.
- If the value of the option is `true`, then the backup or restore operation is aborted and the switchback process continues.

== SMTape backup or restore operation initiated during a switchover or switchback

During a switchover process from cluster 1 to cluster 2, if an SMTape backup or restore operation is initiated on cluster 1, then the backup or restore operation fails and the switchover continues.

During a switchback process from cluster 2 to cluster 1, if an SMTape backup or restore operation is initiated from cluster 2, then the backup or restore operation fails and the switchback continues.

= Monitor tape backup and restore operations for FlexVol volumes

= Monitor tape backup and restore operations for FlexVol volumes overview

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can view the event log files to monitor the tape backup and restore operations. ONTAP automatically logs significant backup and restore events and the time at which they occur in a log file named `backup` in the controller's `/etc/log/` directory. By default, event logging is set to on.

You might want to view event log files for the following reasons:

- Checking whether a nightly backup was successful
- Gathering statistics on backup operations
- For using the information in past event log files to help diagnose problems with backup and restore operations

Once every week, the event log files are rotated. The `/etc/log/backup` file is renamed to `/etc/log/backup.0`, the `/etc/log/backup.0` file is renamed to `/etc/log/backup.1`, and so on. The system saves the log files for up to six weeks; therefore, you can have up to seven message files (`/etc/log/backup.[0-5]` and the current `/etc/log/backup` file).

= Access the event log files

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can access the event log files for tape backup and restore operations in the `/etc/log/` directory by using the `rdfile` command at the nodeshell. You can view these event log files to monitor tape backup and restore operations.

About this task

With additional configurations, such as an access-control role with access to the `spi` web service or a user account set up with the `http` access method, you can also use a web browser to access these log files.

Steps

1. To access the nodeshell, enter the following command:

```
node run -node node_name
```

`node_name` is the name of the node.

2. To access the event log files for tape backup and restore operations, enter the following command:

```
rdfile /etc/log/backup
```

= What the dump and restore event log message format is

= Dump and restore event log message format overview

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

For each dump and restore event, a message is written to the backup log file.

The format of the dump and restore event log message is as follows:

```
type timestamp identifier event (event_info)
```

The following list describes the fields in the event log message format:

- Each log message begins with one of the type indicators described in the following table:

Type	Description
log	Logging event
dmp	Dump event
rst	Restore event

- `timestamp` shows the date and time of the event.
- The `identifier` field for a dump event includes the dump path and the unique ID for the dump. The `identifier` field for a restore event uses only the restore destination path name as a unique identifier. Logging-related event messages do not include an `identifier` field.

= What logging events are

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

The event field of a message that begins with a log specifies the beginning of a logging or the end of a logging.

It contains one of the events shown in the following table:

Event	Description
Start_Logging	Indicates the beginning of logging or that logging has been turned back on after being disabled.
Stop_Logging	Indicates that logging has been turned off.

= What dump events are

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

The event field for a dump event contains an event type followed by event-specific information within parentheses.

The following table describes the events, their descriptions, and the related event information that might be recorded for a dump operation:

Event	Description	Event information
Start	NDMP dump is started	Dump level and the type of dump
End	Dumps completed successfully	Amount of data processed
Abort	The operation is cancelled	Amount of data processed
Options	Specified options are listed	All options and their associated values, including NDMP options
Tape_open	The tape is open for read/write	The new tape device name
Tape_close	The tape is closed for read/write	The tape device name
Phase-change	A dump is entering a new processing phase	The new phase name
Error	A dump has encountered an unexpected event	Error message
Snapshot	A Snapshot copy is created or located	The name and time of the Snapshot copy
Base_dump	A base dump entry in the internal metafile has been located	The level and time of the base dump (for incremental dumps only)

= What restore events are

:icons: font

```
:relative_path: ./tape-backup/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/
```

The event field for a restore event contains an event type followed by event-specific information in parentheses.

The following table provides information about the events, their descriptions, and the related event information that can be recorded for a restore operation:

Event	Description	Event information
Start	NDMP restore is started	Restore level and the type of restore
End	Restores completed successfully	Number of files and amount of data processed
Abort	The operation is cancelled	Number of files and amount of data processed
Options	Specified options are listed	All options and their associated values, including NDMP options
Tape_open	The tape is open for read/write	The new tape device name
Tape_close	The tape is closed for read/write	The tape device name
Phase-change	Restore is entering a new processing phase	The new phase name
Error	Restore encounters an unexpected event	Error message

= Enabling or disabling event logging

:icons: font

```
:relative_path: ./tape-backup/
```

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/
```

You can turn the event logging on or off.

Steps

1. To enable or disable event logging, enter the following command at the clustershell:

```
options -option_name backup.log.enable -option-value {on | off}
```

on turns event logging on.

off turns event logging off.

Event logging is turned on by default.

= Error messages for tape backup and restore of FlexVol volumes

= Backup and restore error messages

= Resource limitation: no available thread

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Resource limitation: no available thread

- **Cause**

The maximum number of active local tape I/O threads is currently in use. You can have a maximum of 16 active local tape drives.

- **Corrective action**

Wait for some tape jobs to finish before starting a new backup or restore job.

= Tape reservation preempted

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Tape reservation preempted

- **Cause**

The tape drive is in use by another operation or the tape has been closed prematurely.

- **Corrective action**

Ensure that the tape drive is not in use by another operation and that the DMA application has not aborted the job and then retry.

= Could not initialize media

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Could not initialize media

- **Cause**

You might get this error for one of the following reasons:

- The tape drive used for the backup is corrupt or damaged.
- The tape does not contain the complete backup or is corrupt.
- The maximum number of active local tape I/O threads is currently in use.

You can have a maximum of 16 active local tape drives.

- **Corrective action**

- If the tape drive is corrupt or damaged, retry the operation with a valid tape drive.
- If the tape does not contain the complete backup or is corrupt, you cannot perform the restore operation.
- If tape resources are not available, wait for some of the backup or restore jobs to finish and then retry the operation.

= Maximum number of allowed dumps or restores (maximum session limit) in progress

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Maximum number of allowed dumps or restores (*maximum session limit*) in progress

- **Cause**

The maximum number of backup or restore jobs is already running.

- **Corrective action**

Retry the operation after some of the currently running jobs have finished.

= Media error on tape write

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Media error on tape write

- **Cause**

The tape used for the backup is corrupted.

- **Corrective action**

Replace the tape and retry the backup job.

= Tape write failed

:icons: font

```
:relative_path: ./tape-backup/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

- **Message**

Tape write failed

- **Cause**

The tape used for the backup is corrupted.

- **Corrective action**

Replace the tape and retry the backup job.

= Tape write failed - new tape encountered media error

:icons: font

```
:relative_path: ./tape-backup/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

- **Message**

Tape write failed - new tape encountered media error

- **Cause**

The tape used for the backup is corrupted.

- **Corrective action**

Replace the tape and retry the backup.

= Tape write failed - new tape is broken or write protected

:icons: font

```
:relative_path: ./tape-backup/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

- **Message**

Tape write failed - new tape is broken or write protected

- **Cause**

The tape used for the backup is corrupted or write-protected.

- **Corrective action**

Replace the tape and retry the backup.

= Tape write failed - new tape is already at the end of media

:icons: font

```
:relative_path: ./tape-backup/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

- **Message**

Tape write failed - new tape is already at the end of media

- **Cause**

There is not enough space on the tape to complete the backup.

- **Corrective action**

Replace the tape and retry the backup.

= Tape write error

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Tape write error - The previous tape had less than the required minimum capacity, size MB, for this tape operation, The operation should be restarted from the beginning

- **Cause**

The tape capacity is insufficient to contain the backup data.

- **Corrective action**

Use tapes with larger capacity and retry the backup job.

= Media error on tape read

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Media error on tape read

- **Cause**

The tape from which data is being restored is corrupted and might not contain the complete backup data.

- **Corrective action**

If you are sure that the tape has the complete backup, retry the restore operation. If the tape does not contain the complete backup, you cannot perform the restore operation.

= Tape read error

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Tape read error

- **Cause**

The tape drive is damaged or the tape does not contain the complete backup.

- **Corrective action**

If the tape drive is damaged, use another tape drive. If the tape does not contain the complete backup, you cannot restore the data.

= Already at the end of tape

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

- **Message**

Already at the end of tape

- **Cause**

The tape does not contain any data or must be rewound.

- **Corrective action**

If the tape does not contain data, use the tape that contains the backup and retry the restore job. Otherwise, rewind the tape and retry the restore job.

= Tape record size is too small. Try a larger size.

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

- **Message**

Tape record size is too small. Try a larger size.

- **Cause**

The blocking factor specified for the restore operation is smaller than the blocking factor that was used during the backup.

- **Corrective action**

Use the same blocking factor that was specified during the backup.

= Tape record size should be block_size1 and not block_size2

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

- **Message**

Tape record size should be block_size1 and not block_size2

- **Cause**

The blocking factor specified for the local restore is incorrect.

- **Corrective action**

Retry the restore job with block_size1 as the blocking factor.

= Tape record size must be in the range between 4KB and 256KB

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Tape record size must be in the range between 4KB and 256KB

- **Cause**

The blocking factor specified for the backup or restore operation is not within the permitted range.

- **Corrective action**

Specify a blocking factor in the range of 4 KB to 256 KB.

= NDMP error messages

Destination qtree is read-only

- **Cause**

The qtree to which the restore is attempted to is read-only.

- **Corrective action**

Try restoring the data to a different location.

= Dumps temporarily disabled on volume, try again

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Dumps temporarily disabled on volume, try again

- **Cause**

NDMP dump backup is attempted on a SnapMirror destination volume that is part of either a snapmirror break or a snapmirror resync operation.

- **Corrective action**

Wait for the snapmirror break or snapmirror resync operation to finish and then perform the dump operation.

Whenever the state of a SnapMirror destination volume changes from read/write to read-only or from read-only to read/write, you must perform a baseline backup.

= NFS labels not recognized

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Error: Aborting: dump encountered NFS security labels in the file system

- **Cause**

NFS security labels are supported Beginning with ONTAP 9.9.1 when NFSv4.2 is enabled. However, NFS security labels are not currently recognized by the dump engine. If it encounters any NFS security labels on the files, directories, or any special files in any format of dump, the dump fails.

- **Corrective action**

Verify that no files or directories have NFS security labels.

= No files were created

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

No files were created

- **Cause**

A directory DAR was attempted without enabling the enhanced DAR functionality.

- **Corrective action**

Enable the enhanced DAR functionality and retry the DAR.

= Restore of the file <file name> failed
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Restore of the file file name failed

- **Cause**

When a DAR (Direct Access Recovery) of a file whose file name is the same as that of a LUN on the destination volume is performed, then the DAR fails.

- **Corrective action**

Retry DAR of the file.

= Truncation failed for src inode <inode number>...
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Truncation failed for src inode <inode number>. Error <error number>. Skipping inode.

- **Cause**

Inode of a file is deleted when the file is being restored.

- **Corrective action**

Wait for the restore operation on a volume to complete before using that volume.

= Unable to lock a snapshot needed by dump
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Unable to lock a snapshot needed by dump

- **Cause**

The Snapshot copy specified for the backup is not available.

- **Corrective action**

Retry the backup with a different Snapshot copy.

Use the snap list command to see the list of available Snapshot copies.

= Unable to locate bitmap files
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

- **Message**

Unable to locate bitmap files

- **Cause**

The bitmap files required for the backup operation might have been deleted. In this case, the backup cannot be restarted.

- **Corrective action**

Perform the backup again.

= Volume is temporarily in a transitional state
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

- **Message**

Volume is temporarily in a transitional state

- **Cause**

The volume being backed up is temporarily in an unmounted state.

- **Corrective action**

Wait for some time and perform the backup again.

= SMTape error messages

= Chunks out of order
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

- **Message**

Chunks out of order

- **Cause**

The backup tapes are not being restored in the correct sequence.

- **Corrective action**

Retry the restore operation and load the tapes in the correct sequence.

= Chunk format not supported
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Chunk format not supported

- **Cause**

The backup image is not of SMTape.

- **Corrective action**

If the backup image is not of SMTape, retry the operation with a tape that has the SMTape backup.

= Failed to allocate memory
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Failed to allocate memory

- **Cause**

The system has run out of memory.

- **Corrective action**

Retry the job later when the system is not too busy.

= Failed to get data buffer
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Failed to get data buffer

- **Cause**

The storage system ran out of buffers.

- **Corrective action**

Wait for some storage system operations to finish and then retry the job.

= Failed to find snapshot
:icons: font
:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Failed to find snapshot

- **Cause**

The Snapshot copy specified for the backup is unavailable.

- **Corrective action**

Check if the specified Snapshot copy is available. If not, retry with the correct Snapshot copy.

= Failed to create snapshot

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Failed to create snapshot

- **Cause**

The volume already contains the maximum number of Snapshot copies.

- **Corrective action**

Delete some Snapshot copies and then retry the backup operation.

= Failed to lock snapshot

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Failed to lock snapshot

- **Cause**

The Snapshot copy is either in use or has been deleted.

- **Corrective action**

If the Snapshot copy is in use by another operation, wait for that operation to finish and then retry the backup. If the Snapshot copy has been deleted, you cannot perform the backup.

= Failed to delete snapshot

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Failed to delete snapshot

- **Cause**

The auto Snapshot copy could not be deleted because it is in use by other operations.

- **Corrective action**

Use the `snap` command to determine the status of the Snapshot copy. If the Snapshot copy is not required, delete it manually.

= Failed to get latest snapshot

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Failed to get latest snapshot

- **Cause**

The latest Snapshot copy might not exist because the volume is being initialized by SnapMirror.

- **Corrective action**

Retry after initialization is complete.

= Failed to load new tape

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Failed to load new tape

- **Cause**

Error in tape drive or media.

- **Corrective action**

Replace the tape and retry the operation.

= Failed to initialize tape

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Failed to initialize tape

- **Cause**

You might get this error message for one of the following reasons:

- The backup image is not of SMTape.
- The tape blocking factor specified is incorrect.
- The tape is corrupt or damaged.
- The wrong tape is loaded for restore.

- **Corrective action**

- If the backup image is not of SMTape, retry the operation with a tape that has SMTape backup.
- If the blocking factor is incorrect, specify the correct blocking factor and retry the operation.
- If the tape is corrupt, you cannot perform the restore operation.
- If the wrong tape is loaded, retry the operation with the correct tape.

= Failed to initialize restore stream

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Failed to initialize restore stream

- **Cause**

You might get this error message for one of the following reasons:

- The backup image is not of SMTape.
- The tape blocking factor specified is incorrect.
- The tape is corrupt or damaged.
- The wrong tape is loaded for restore.

- **Corrective action**

- If the backup image is not of SMTape, retry the operation with a tape that has the SMTape backup.
- If the blocking factor is incorrect, specify the correct blocking factor and retry the operation.
- If the tape is corrupt, you cannot perform the restore operation.
- If the wrong tape is loaded, retry the operation with the correct tape.

= Failed to read backup image

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Failed to read backup image

- **Cause**

The tape is corrupt.

- **Corrective action**

If the tape is corrupt, you cannot perform the restore operation.

= Image header missing or corrupted

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Image header missing or corrupted

- **Cause**

The tape does not contain a valid SMTape backup.

- **Corrective action**

Retry with a tape containing a valid backup.

= Internal assertion

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Internal assertion

- **Cause**

There is an internal SMTape error.

- **Corrective action**

Report the error and send the etc/log/backup file to technical support.

= Invalid backup image magic number

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Invalid backup image magic number

- **Cause**

The backup image is not of SMTape.

- **Corrective action**

If the backup image is not of SMTape, retry the operation with a tape that has the SMTape backup.

= Invalid backup image checksum

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

- **Message**

Invalid backup image checksum

- **Cause**

The tape is corrupt.

- **Corrective action**

If the tape is corrupt, you cannot perform the restore operation.

= Invalid input tape

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

- **Message**

Invalid input tape

- **Cause**

The signature of the backup image is not valid in the tape header. The tape has corrupted data or does not contain a valid backup image.

- **Corrective action**

Retry the restore job with a valid backup image.

= Invalid volume path

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

- **Message**

Invalid volume path

- **Cause**

The specified volume for the backup or restore operation is not found.

- **Corrective action**

Retry the job with a valid volume path and volume name.

= Mismatch in backup set ID

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Mismatch in backup set ID

- **Cause**

The tape loaded during a tape change is not a part of the backup set.

- **Corrective action**

Load the correct tape and retry the job.

= Mismatch in backup time stamp

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Mismatch in backup time stamp

- **Cause**

The tape loaded during a tape change is not a part of the backup set.

- **Corrective action**

Use the `smtape restore -h` command to verify the header information of a tape.

= Job aborted due to shutdown

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Job aborted due to shutdown

- **Cause**

The storage system is being rebooted.

- **Corrective action**

Retry the job after the storage system reboots.

= Job aborted due to Snapshot autodelete

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Job aborted due to Snapshot autodelete

- **Cause**

The volume does not have enough space and has triggered the automatic deletion of Snapshot copies.

- **Corrective action**

Free up space in the volume and retry the job.

= Tape is currently in use by other operations

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Tape is currently in use by other operations

- **Cause**

The tape drive is in use by another job.

- **Corrective action**

Retry the backup after the currently active job is finished.

= Tapes out of order

:icons: font

:relative_path: ./tape-backup/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Tapes out of order

- **Cause**

The first tape of the tape sequence for the restore operation does not have the image header.

- **Corrective action**

Load the tape with the image header and retry the job.

= Transfer failed (Aborted due to MetroCluster operation)
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

- **Message**

Transfer failed (Aborted due to MetroCluster operation)

- **Cause**

The SMTape operation is aborted because of a switchover or switchback operation.

- **Corrective action**

Perform the SMTape operation after the switchover or switchback operation finishes.

= Transfer failed (ARL initiated abort)
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

- **Message**

Transfer failed (ARL initiated abort)

- **Cause**

While an SMTape operation is in progress if an aggregate relocation is initiated, then the SMTape operation is aborted.

- **Corrective action**

Perform the SMTape operation after the aggregate relocation operation finishes.

= Transfer failed (CFO initiated abort)
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

- **Message**

Transfer failed (CFO initiated abort)

- **Cause**

The SMTape operation is aborted because of a storage failover (takeover and giveback) operation of a CFO aggregate.

- **Corrective action**

Perform the SMTape operation after the storage failover of the CFO aggregate finishes.

= Transfer failed (SFO initiated abort)
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Transfer failed (SFO initiated abort)

- **Cause**

The SMTape operation is aborted because of a storage failover (takeover and giveback) operation.

- **Corrective action**

Perform the SMTape operation after the storage failover (takeover and giveback) operation finishes.

= Underlying aggregate under migration
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Underlying aggregate under migration

- **Cause**

If an SMTape operation is initiated on an aggregate that is under migration (storage failover or aggregate relocation), then the SMTape operation fails.

- **Corrective action**

Perform the SMTape operation after the aggregate migration finishes.

= Volume is currently under migration
:icons: font
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

- **Message**

Volume is currently under migration

- **Cause**

Volume migration and SMTape backup cannot run simultaneously.

- **Corrective action**

Retry the backup job after the volume migration is complete.

= Volume offline
:icons: font

```
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

- **Message**

Volume offline

- **Cause**

The volume being backed up is offline.

- **Corrective action**

Bring the volume online and retry the backup.

= Volume not restricted

:icons: font

```
:relative_path: ./tape-backup/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

- **Message**

Volume not restricted

- **Cause**

The destination volume to which data is being restored is not restricted.

- **Corrective action**

Restrict the volume and retry the restore operation.

= NDMP configuration

= NDMP configuration overview

:icons: font

```
:relative_path: ./ndmp/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

You can quickly configure an ONTAP 9 cluster to use the Network Data Management Protocol (NDMP) to back up data directly to tape using a third-party backup application.

Configure NDMP in the following circumstances:

- The cluster is running ONTAP 9.
- You have a third-party backup application (also called a Data Management Application or DMA).
- You are a cluster administrator.
- You want to perform backup operations either at the cluster level (using the admin storage virtual machine (SVM)) or node level.
- Tape devices and an optional media server are installed.

- Tape devices are connected to the cluster through a Fibre Channel (FC) switch and not directly attached.
- At least one tape device has a logical unit number (LUN) of 0.

Related information

[Data protection using tape backup.](#)

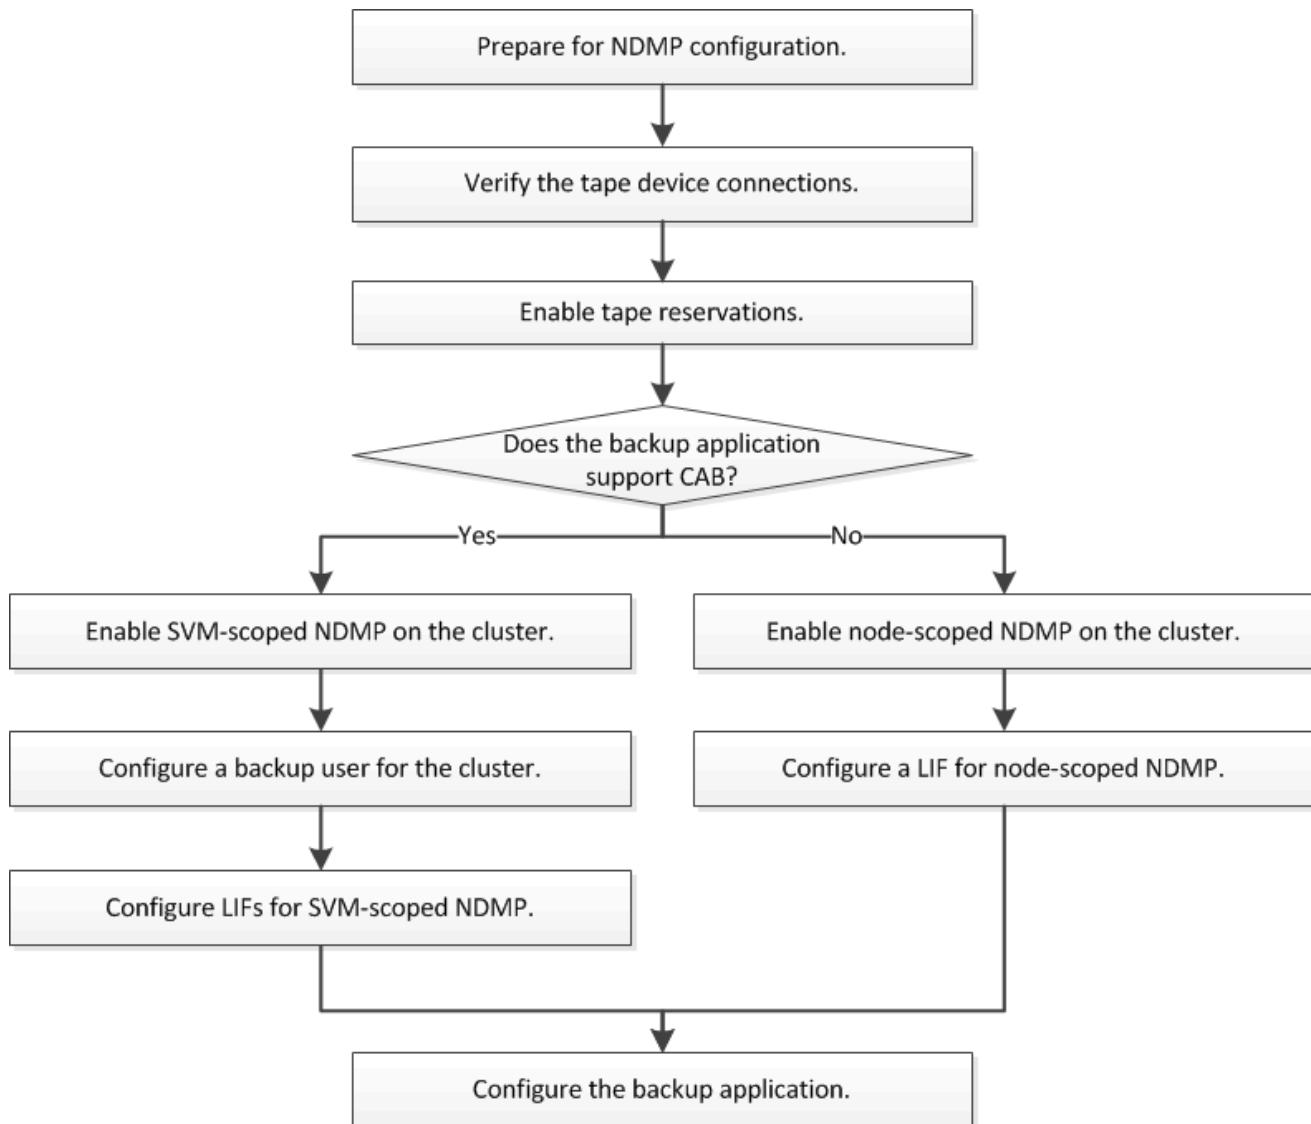

= NDMP configuration workflow

:icons: font

:relative_path: ./ndmp/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

Setting up tape backup over NDMP involves preparing for NDMP configuration, verifying the tape device connections, enabling tape reservations, configuring NDMP at the SVM or node level, enabling NDMP on the cluster, configuring a backup user, configuring LIFs, and configuring the backup application.

= Prepare for NDMP configuration

:icons: font

```
:relative_path: ./ndmp/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/
```

Before you configure tape backup access over Network Data Management Protocol (NDMP), you must verify that the planned configuration is supported, verify that your tape drives are listed as qualified drives on each node, verify that all nodes have intercluster LIFs, and identify whether the backup application supports the Cluster Aware Backup (CAB) extension.

Steps

1. Verify that the planned configuration is supported by using the Interoperability Matrix (IMT).

[NetApp Interoperability Matrix Tool](#)

You should verify that the following components are compatible:

- The version of ONTAP 9 that is running on the cluster.
- The backup application vendor and application version: for example, Symantec NetBackup 7.6 or CommVault Simpana 10 SP8.
- The tape devices details, such as the manufacturer, model, and interface of the tape drives: for example, IBM Ultrium-TD4 FC or HP Ultrium-5 SAS.
- The platforms of the nodes in the cluster: for example, FAS3260 or FAS6280.

2. Verify that your tape drives are listed as qualified drives in each node's built-in tape configuration file:

- a. On the command line-interface, view the built-in tape configuration file by using the `storage tape show-supported-status` command.

```
cluster1::> storage tape show-supported-status  
  
Node: cluster1-1  
-----  
Tape Drives Is Supported Support Status  
-----  
-----  
Certance Ultrium 2 true Dynamically Qualified  
Certance Ultrium 3 true Dynamically Qualified  
Digital DLT2000 true Qualified  
....
```

- b. Compare your tape drives to the list of qualified drives in the output.

The names of the tape devices in the output might vary slightly from the names on the device label or in the Interoperability Matrix. For example, Digital DLT2000 can also be known as DLT2k. You can ignore these minor naming differences.

- c. If a device is not listed as qualified in the output even though the device is qualified according to the Interoperability Matrix, download and install an updated configuration file for the device using the instructions on the NetApp Support Site.

NetApp Downloads: Tape Device Configuration Files

A qualified device might not be listed in the built-in tape configuration file if the tape device was qualified after the node was shipped.

3. Verify that every node in the cluster has an intercluster LIF:

- View the intercluster LIFs on the nodes by using the `network interface show -role intercluster` command.

```
cluster1::> network interface show -role intercluster

      Logical      Status      Network      Current
Current Is
Vserver     Interface   Admin/Oper Address/Mask      Node
Port       Home
----- -----
----- -----
cluster1     IC1        up/up       192.0.2.65/24    cluster1-1
e0a         true
```

- If an intercluster LIF does not exist on any node, create an intercluster LIF by using the `network interface create` command.

```
cluster1::> network interface create -vserver cluster1 -lif IC2
          -role intercluster
          -home-node cluster1-2 -home-port e0b -address 192.0.2.68 -netmask
          255.255.255.0
          -status-admin up -failover-policy local-only -firewall-policy
          intercluster

cluster1::> network interface show -role intercluster

      Logical      Status      Network      Current
Current Is
Vserver     Interface   Admin/Oper Address/Mask      Node
Port       Home
----- -----
----- -----
cluster1     IC1        up/up       192.0.2.65/24    cluster1-1
e0a         true
cluster1     IC2        up/up       192.0.2.68/24    cluster1-2
e0b         true
```

Network management

4. Identify whether the backup application supports Cluster Aware Backup (CAB) by using the documentation provided with the backup application.

CAB support is a key factor in determining the type of backup you can perform.

= Verify tape device connections

:icons: font

:relative_path: ./ndmp/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You must ensure that all drives and media changers are visible in ONTAP as devices.

Steps

1. View information about all drives and media changers by using the `storage tape show` command.

```
cluster1::> storage tape show

Node: cluster1-01
Device ID          Device Type      Description
Status
-----
-----
sw4:10.11          tape drive       HP LTO-3
normal
0b.125L1           media changer   HP MSL G3 Series
normal
0d.4               tape drive       IBM LTO 5 ULT3580
normal
0d.4L1              media changer   IBM 3573-TL
normal
...
...
```

2. If a tape drive is not displayed, troubleshoot the problem.
3. If a media changer is not displayed, view information about media changers by using the `storage tape show-media-changer` command, and then troubleshoot the problem.

```

cluster1::> storage tape show-media-changer

Media Changer: sw4:10.11L1
    Description: PX70-TL
        WWNN: 2:00a:000e11:10b919

...

```

= Enable tape reservations

:icons: font

:relative_path: ./ndmp/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You must ensure that tape drives are reserved for use by backup applications for NDMP backup operations.

About this task

The reservation settings vary in different backup applications, and these settings must match the backup application and the nodes or servers using the same drives. See the vendor documentation of the backup application for the correct reservation settings.

Steps

1. Enable reservations by using the options -option-name tape.reservations -option-value persistent command.

The following command enables reservations with the persistent value:

```

cluster1::> options -option-name tape.reservations -option-value
persistent
2 entries were modified.

```

2. Verify that reservations are enabled on all nodes by using the options tape.reservations command, and then review the output.

```
cluster1::> options tape.reservations

cluster1-1
    tape.reservations           persistent

cluster1-2
    tape.reservations           persistent
2 entries were displayed.
```

= Configure NDMP at the SVM level or the node level

= Configure NDMP at the SVM level or the node level overview

:icons: font
:relative_path: ./ndmp/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

If the backup application supports Cluster Aware Backup (CAB), you can configure NDMP as SVM-scoped at the cluster (admin SVM) level, which enables you to back up all volumes hosted across different nodes of the cluster. Otherwise, you can configure node-scoped NDMP, which enables you to back up all the volumes hosted on that node.

= Configure SVM-scoped NDMP

= Configure SVM-scoped NDMP overview
:icons: font
:relative_path: ./ndmp/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

If the DMA supports the Cluster Aware Backup (CAB) extension, you can back up all the volumes hosted across different nodes in a cluster by enabling SVM-scoped NDMP, configuring a backup user account, and configuring LIFs for data and control connection.

What you'll need

The CAB extension must be supported by the DMA.

= Enable SVM-scoped NDMP on the cluster

:icons: font
:relative_path: ./ndmp/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can configure SVM-scoped NDMP on the cluster by enabling SVM-scoped NDMP mode and NDMP service on the cluster (admin SVM).

About this task

Turning off node-scoped NDMP mode enables SVM-scoped NDMP mode on the cluster.

Steps

1. Enable SVM-scoped NDMP mode by using the `system services ndmp` command with the `node-scope-mode` parameter.

```
cluster1::> system services ndmp node-scope-mode off  
NDMP node-scope-mode is disabled.
```

2. Enable NDMP service on the admin SVM by using the `vserver services ndmp on` command.

```
cluster1::> vserver services ndmp on -vserver cluster1
```

The authentication type is set to `challenge` by default and plaintext authentication is disabled.

For secure communication, you should keep plaintext authentication disabled.

3. Verify that NDMP service is enabled by using the `vserver services ndmp show` command.

```
cluster1::> vserver services ndmp show  
  
Vserver      Enabled      Authentication type  
-----  
cluster1      true        challenge  
vs1          false       challenge
```

= Configure a backup user for the cluster

:icons: font

:relative_path: ./ndmp/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

To authenticate NDMP from the backup application, you must create a local backup user, or an NIS or LDAP user for the cluster with the admin or backup role, and generate an NDMP password for the backup user.

What you'll need

If you are using an NIS or LDAP user, the user must be created on the respective server. You cannot use an Active Directory user.

Steps

1. Create a backup user with the `admin` or `backup` role by using the `security login create` command.

You can specify a local backup user name or an NIS or LDAP user name for the `-user-or-group-name` parameter.

The following command creates the backup user `backup_admin1` with the `backup` role:

```
cluster1::> security login create -user-or-group-name backup_admin1  
-application ssh  
-authmethod password -role backup  
  
Please enter a password for user 'backup_admin1':  
Please enter it again:
```

2. Generate a password for the admin SVM by using the vserver services ndmp generate password command.

The generated password must be used to authenticate the NDMP connection by the backup application.

```
cluster1::> vserver services ndmp generate-password -vserver  
cluster1 -user backup_admin1  
  
Vserver: cluster1  
User: backup_admin1  
Password: qG5CqQHYxw7tE57g
```

= Configure LIFs

```
:icons: font  
:relative_path: ./ndmp/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

You must identify the LIFs that will be used for establishing a data connection between the data and tape resources, and for control connection between the admin SVM and the backup application. After identifying the LIFs, you must verify that firewall and failover policies are set for the LIFs, and specify the preferred interface role.

Steps

1. Identify the intercluster, cluster-management, and node-management LIFs by using the network interface show command with the -role parameter.

The following command displays the intercluster LIFs:

```
cluster1::> network interface show -role intercluster
```

Current Is	Logical	Status	Network	Current
Vserver	Interface	Admin/Oper	Address/Mask	Node
Port	Home			
cluster1	IC1	up/up	192.0.2.65/24	
cluster1-1	e0a	true		
cluster1	IC2	up/up	192.0.2.68/24	
cluster1-2	e0b	true		

The following command displays the cluster-management LIF:

```
cluster1::> network interface show -role cluster-mgmt
```

Current Is	Logical	Status	Network	Current
Vserver	Interface	Admin/Oper	Address/Mask	Node
Port	Home			
cluster1	cluster_mgmt	up/up	192.0.2.60/24	
cluster1-2	e0M	true		

The following command displays the node-management LIFs:

```
cluster1::> network interface show -role node-mgmt
```

Current Is	Logical	Status	Network	Current
Vserver	Interface	Admin/Oper	Address/Mask	Node
Port	Home			
cluster1	cluster1-1_mgmt1	up/up	192.0.2.69/24	
cluster1-1	e0M	true		
	cluster1-2_mgmt1	up/up	192.0.2.70/24	
cluster1-2	e0M	true		

2. Ensure that the firewall policy is enabled for NDMP on the intercluster, cluster-management (cluster-mgmt), and node-management (node-mgmt) LIFs:

- a. Verify that the firewall policy is enabled for NDMP by using the system services firewall policy show command.

The following command displays the firewall policy for the cluster-management LIF:

```
cluster1::> system services firewall policy show -policy cluster
```

Vserver	Policy	Service	Allowed
cluster	cluster	dns	0.0.0.0/0
		http	0.0.0.0/0
		https	0.0.0.0/0
		** ndmp	0.0.0.0/0**
		ndmps	0.0.0.0/0
		ntp	0.0.0.0/0
		rsh	0.0.0.0/0
		snmp	0.0.0.0/0
		ssh	0.0.0.0/0
		telnet	0.0.0.0/0

10 entries were displayed.

The following command displays the firewall policy for the intercluster LIF:

```
cluster1::> system services firewall policy show -policy intercluster
```

Vserver	Policy	Service	Allowed
cluster1	intercluster	dns	-
		http	-
		https	-
		ndmp	0.0.0.0/0, ::/0
		ndmps	-
		ntp	-
		rsh	-
		ssh	-
		telnet	-

9 entries were displayed.

The following command displays the firewall policy for the node-management LIF:

```

cluster1::> system services firewall policy show -policy mgmt

Vserver      Policy       Service     Allowed
-----        -----        -----
cluster1-1    mgmt        dns         0.0.0.0/0, ::/0
                           http        0.0.0.0/0, ::/0
                           https       0.0.0.0/0, ::/0
                           **ndmp      0.0.0.0/0, ::/0**
                           ndmps       0.0.0.0/0, ::/0
                           ntp         0.0.0.0/0, ::/0
                           rsh         -
                           snmp       0.0.0.0/0, ::/0
                           ssh         0.0.0.0/0, ::/0
                           telnet      -
10 entries were displayed.

```

- b. If the firewall policy is not enabled, enable the firewall policy by using the `system services firewall policy modify` command with the `-service` parameter.

The following command enables firewall policy for the intercluster LIF:

```

cluster1::> system services firewall policy modify -vserver
cluster1 -policy intercluster -service ndmp 0.0.0.0/0

```

3. Ensure that the failover policy is set appropriately for all the LIFs:

- a. Verify that the failover policy for the cluster-management LIF is set to broadcast-domain-wide, and the policy for the intercluster and node-management LIFs is set to local-only by using the `network interface show -failover` command.

The following command displays the failover policy for the cluster-management, intercluster, and node-management LIFs:

```

cluster1::> network interface show -failover

      Logical          Home          Failover
Failover

Default**                                     Failover
Targets:                                     .....
                                                .....
**IC2           cluster1-1:e0b    local-only
Default**                                     Failover
Targets:                                     .....
                                                .....
**cluster1-1 cluster1-1_mgmt1  cluster1-1:e0m    local-only
Default**                                     Failover
Targets:                                     .....
                                                .....
**cluster1-2 cluster1-2_mgmt1  cluster1-2:e0m    local-only
Default**                                     Failover
Targets:                                     .....
                                                .....

```

- b. If the failover policies are not set appropriately, modify the failover policy by using the `network interface modify` command with the `-failover-policy` parameter.

```

cluster1::> network interface modify -vserver cluster1 -lif IC1
-failover-policy local-only

```

4. Specify the LIFs that are required for data connection by using the `vserver services ndmp modify` command with the `preferred-interface-role` parameter.

```
cluster1::> vserver services ndmp modify -vserver cluster1  
-preferred-interface-role intercluster,cluster-mgmt,node-mgmt
```

5. Verify that the preferred interface role is set for the cluster by using the `vserver services ndmp show` command.

```
cluster1::> vserver services ndmp show -vserver cluster1  
  
          Vserver: cluster1  
          NDMP Version: 4  
          .....  
          .....  
          Preferred Interface Role: intercluster, cluster-mgmt,  
node-mgmt
```

= Configure node-scoped NDMP

= Enable node-scoped NDMP on the cluster

:icons: font

:relative_path: ./ndmp/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can back up volumes hosted on a node by enabling node-scoped NDMP, setting up the password for the root user, and configuring a LIF for data and control connection.

You can configure node-scoped NDMP by enabling node-scoped NDMP on the cluster and NDMP service on all nodes of the cluster. You must also configure the `root` user for NDMP when enabling the NDMP service.

Steps

1. Enable node-scoped NDMP mode by using the `system services ndmp` command with the `node-scope-mode` parameter.

```
cluster1::> system services ndmp node-scope-mode on  
NDMP node-scope-mode is enabled.
```

2. Enable NDMP service on all nodes in the cluster by using the `system services ndmp on` command.

Using the wildcard “*” enables NDMP service on all nodes at the same time.

You must specify a password for authentication of the NDMP connection by the backup application.

```
cluster1::> system services ndmp on -node *
Please enter password:
Confirm password:
2 entries were modified.
```

3. Disable the `-clear-text` option for secure communication of the NDMP password by using the `system services ndmp modify` command.

Using the wildcard “*” disables the `-clear-text` option on all nodes at the same time.

```
cluster1::> system services ndmp modify -node * -clear-text false
2 entries were modified.
```

4. Verify that NDMP service is enabled and the `-clear-text` option is disabled by using the `system services ndmp show` command.

```
cluster1::> system services ndmp show
Node           Enabled   Clear text   User Id
-----
cluster1-1      true      false       root
cluster1-2      true      false       root
2 entries were displayed.
```

= Configure a LIF

:icons: font

:relative_path: ./ndmp/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You must identify a LIF that will be used for establishing a data connection and control connection between the node and the backup application. After identifying the LIF, you must verify that firewall and failover policies are set for the LIF.

Steps

1. Identify the intercluster LIF hosted on the nodes by using the `network interface show` command with the `-role` parameter.

```

cluster1::> network interface show -role intercluster

      Logical     Status     Network      Current
Current Is
Vserver    Interface Admin/Oper Address/Mask      Node
Port       Home
----- -----
----- -----
cluster1    IC1        up/up      192.0.2.65/24    cluster1-1
e0a        true
cluster1    IC2        up/up      192.0.2.68/24    cluster1-2
e0b        true

```

2. Ensure that the firewall policy is enabled for NDMP on the intercluster LIFs:

- a. Verify that the firewall policy is enabled for NDMP by using the `system services firewall policy show` command.

The following command displays the firewall policy for the intercluster LIF:

```

cluster1::> system services firewall policy show -policy
intercluster

Vserver    Policy      Service      Allowed
----- -----
cluster1   intercluster dns          -
                           http         -
                           https        -
                           **ndmp      0.0.0.0/0, ::/0**
                           ndmps        -
                           ntp          -
                           rsh          -
                           ssh          -
                           telnet        -

```

9 entries were displayed.

- b. If the firewall policy is not enabled, enable the firewall policy by using the `system services firewall policy modify` command with the `-service` parameter.

The following command enables firewall policy for the intercluster LIF:

```

cluster1::> system services firewall policy modify -vserver
cluster1 -policy intercluster -service ndmp 0.0.0.0/0

```

3. Ensure that the failover policy is set appropriately for the intercluster LIFs:

- a. Verify that the failover policy for the intercluster LIFs is set to local-only by using the network interface show -failover command.

```
cluster1::> network interface show -failover
      Logical          Home          Failover
Failover
Vserver    Interface     Node:Port   Policy      Group
-----  -----
-----  -----
cluster1    **IC1        cluster1-1:e0a  local-only
Default**                                Failover
Targets:
      .....  .....
      **IC2        cluster1-2:e0b  local-only
Default**                                Failover
Targets:
      .....  .....
cluster1-1  cluster1-1_mgmt1  cluster1-1:e0m  local-only
Default                                Failover
Targets:
      .....  .....
```

- b. If the failover policy is not set appropriately, modify the failover policy by using the network interface modify command with the -failover-policy parameter.

```
cluster1::> network interface modify -vserver cluster1 -lif IC1
-failover-policy local-only
```

= Configure the backup application

:icons: font

:relative_path: ./ndmp/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

After the cluster is configured for NDMP access, you must gather information from the cluster configuration and then configure the rest of the backup process in the backup application.

Steps

1. Gather the following information that you configured earlier in ONTAP:

- The user name and password that the backup application requires to create the NDMP connection

- The IP addresses of the intercluster LIFs that the backup application requires to connect to the cluster
2. In ONTAP, display the aliases that ONTAP assigned to each device by using the `storage tape alias show` command.

The aliases are often useful in configuring the backup application.

```
cluster1::> storage tape show -alias

Device ID: 2a.0
Device Type: tape drive
Description: Hewlett-Packard LTO-5

Node           Alias      Mapping
-----
stsw-3220-4a-4b-02    st2      SN [HU19497WVR]
...

```

3. In the backup application, configure the rest of the backup process by using the backup application's documentation.

After you finish

If a data mobility event occurs, such as a volume move or LIF migration, you must be prepared to reinitialize any interrupted backup operations.

= Replication between NetApp Element software and ONTAP

= Replication between NetApp Element software and ONTAP overview

:icons: font

:relative_path: ./element-replication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can ensure business continuity on an Element system by using SnapMirror to replicate Snapshot copies of an Element volume to an ONTAP destination. In the event of a disaster at the Element site, you can serve data to clients from the ONTAP system, and then reactivate the Element system when service is restored.

Beginning with ONTAP 9.4, you can replicate Snapshot copies of a LUN created on an ONTAP node back to an Element system. You might have created a LUN during an outage at the Element site, or you might be using a LUN to migrate data from ONTAP to Element software.

You should work with Element to ONTAP backup if the following apply:

- You want to use best practices, not explore every available option.
- You want to use the ONTAP command-line interface (CLI), not System Manager or an automated scripting tool.
- You are using iSCSI to serve data to clients.

If you require additional configuration or conceptual information, see the following documentation:

- Element configuration

[NetApp Element software documentation](#)

- SnapMirror concepts and configuration

[Data protection overview](#)

== About replication between Element and ONTAP

Beginning with ONTAP 9.3, you can use SnapMirror to replicate Snapshot copies of an Element volume to an ONTAP destination. In the event of a disaster at the Element site, you can serve data to clients from the ONTAP system, then reactivate the Element source volume when service is restored.

Beginning with ONTAP 9.4, you can replicate Snapshot copies of a LUN created on an ONTAP node back to an Element system. You might have created a LUN during an outage at the Element site, or you might be using a LUN to migrate data from ONTAP to Element software.

== Types of data protection relationship

SnapMirror offers two types of data protection relationship. For each type, SnapMirror creates a Snapshot copy of the Element source volume before initializing or updating the relationship:

- In a *disaster recovery (DR)* data protection relationship, the destination volume contains only the Snapshot copy created by SnapMirror, from which you can continue to serve data in the event of a catastrophe at the primary site.
- In a *long-term retention* data protection relationship, the destination volume contains point-in-time Snapshot copies created by Element software, as well as the Snapshot copy created by SnapMirror. You might want to retain monthly Snapshot copies created over a 20-year span, for example.

== Default policies

The first time you invoke SnapMirror, it performs a *baseline transfer* from the source volume to the destination volume. The *SnapMirror policy* defines the contents of the baseline and any updates.

You can use a default or custom policy when you create a data protection relationship. The *policy type* determines which Snapshot copies to include and how many copies to retain.

The table below shows the default policies. Use the `MirrorLatest` policy to create a traditional DR relationship. Use the `MirrorAndVault` or `Unified7year` policy to create a unified replication relationship, in which DR and long-term retention are configured on the same destination volume.

Policy	Policy Type	Update behavior
<code>MirrorLatest</code>	<code>async-mirror</code>	Transfer the Snapshot copy created by SnapMirror.
<code>MirrorAndVault</code>	<code>mirror-vault</code>	Transfer the Snapshot copy created by SnapMirror and any less recent Snapshot copies made since the last update, provided they have SnapMirror labels “daily” or “weekly”.

Unified7year	mirror-vault	Transfer the Snapshot copy created by SnapMirror and any less recent Snapshot copies made since the last update, provided they have SnapMirror labels “daily”, “weekly”, or “monthly”.
--------------	--------------	--

For complete background information on SnapMirror policies, including guidance on which policy to use, see [Data Protection](#).

== Understanding SnapMirror labels

Every policy with the “mirror-vault” policy type must have a rule that specifies which Snapshot copies to replicate. The rule “daily”, for example, indicates that only Snapshot copies assigned the SnapMirror label “daily” should be replicated. You assign the SnapMirror label when you configure Element Snapshot copies.

== Replication from an Element source cluster to an ONTAP destination cluster

You can use SnapMirror to replicate Snapshot copies of an Element volume to an ONTAP destination system. In the event of a disaster at the Element site, you can serve data to clients from the ONTAP system, then reactivate the Element source volume when service is restored.

An Element volume is roughly equivalent to an ONTAP LUN. SnapMirror creates a LUN with the name of the Element volume when a data protection relationship between Element software and ONTAP is initialized. SnapMirror replicates data to an existing LUN if the LUN meets the requirements for Element to ONTAP replication.

Replication rules are as follows:

- An ONTAP volume can contain data from one Element volume only.
- You cannot replicate data from an ONTAP volume to multiple Element volumes.

== Replication from an ONTAP source cluster to an Element destination cluster

Beginning with ONTAP 9.4, you can replicate Snapshot copies of a LUN created on an ONTAP system back to an Element volume:

- If a SnapMirror relationship already exists between an Element source and an ONTAP destination, a LUN created while you are serving data from the destination is automatically replicated when the source is reactivated.
- Otherwise, you must create and initialize a SnapMirror relationship between the ONTAP source cluster and the Element destination cluster.

Replication rules are as follows:

- The replication relationship must have a policy of type “async-mirror”.
- Policies of type “mirror-vault” are not supported.
- Only iSCSI LUNs are supported.
 - You cannot replicate more than one LUN from an ONTAP volume to an Element volume.
 - You cannot replicate a LUN from an ONTAP volume to multiple Element volumes.

== Prerequisites

You must have completed the following tasks before configuring a data protection relationship between Element and ONTAP:

- The Element cluster must be running NetApp Element software version 10.1 or later.
- The ONTAP cluster must be running ONTAP 9.3 or later.
- SnapMirror must have been licensed on the ONTAP cluster.
- You must have configured volumes on the Element and ONTAP clusters that are large enough to handle anticipated data transfers.
- If you are using the “mirror-vault” policy type, a SnapMirror label must have been configured for the Element Snapshot copies to be replicated.

You can perform this task in the Element software web UI only. For more information, see the [NetApp Element software documentation](#)

- You must have ensured that port 5010 is available.
- If you foresee that you might need to move a destination volume, you must have ensured that full-mesh connectivity exists between the source and destination. Every node on the Element source cluster must be able to communicate with every node on the ONTAP destination cluster.

== Support details

The following table shows support details for Element to ONTAP backup.

Resource or feature	Support details
SnapMirror	<ul style="list-style-type: none">• The SnapMirror restore feature is not supported.• The <code>MirrorAllSnapshots</code> and <code>XDPDefault</code> policies are not supported.• The “vault” policy type is not supported.• The system-defined rule “all_source_snapshots” is not supported.• The “mirror-vault” policy type is supported only for replication from Element software to ONTAP. Use “async-mirror” for replication from ONTAP to Element software.• The <code>-schedule</code> and <code>-prefix</code> options for <code>snapmirror policy add-rule</code> are not supported.• The <code>-preserve</code> and <code>-quick-resync</code> options for <code>snapmirror resync</code> are not supported.• Storage efficiency is not preserved.• Fan-out and cascade data protection deployments are not supported.
ONTAP	<ul style="list-style-type: none">• ONTAP Select is supported beginning with ONTAP 9.4 and Element 10.3.• Cloud Volumes ONTAP is supported beginning with ONTAP 9.5 and Element 11.0.

Element	<ul style="list-style-type: none"> Volume size limit is 8 TiB. Volume block size must be 512 bytes. A 4K byte block size is not supported. Volume size must be a multiple of 1 MiB. Volume attributes are not preserved. Maximum number of Snapshot copies to be replicated is 30.
Network	<ul style="list-style-type: none"> A single TCP connection is allowed per transfer. The Element node must be specified as an IP address. DNS hostname lookup is not supported. IPspaces are not supported.
SnapLock	SnapLock volumes are not supported.
FlexGroup	FlexGroup volumes are not supported.
SVM DR	ONTAP volumes in an SVM DR configuration are not supported.
MetroCluster	ONTAP volumes in a MetroCluster configuration are not supported.

= Workflow for replication between Element and ONTAP

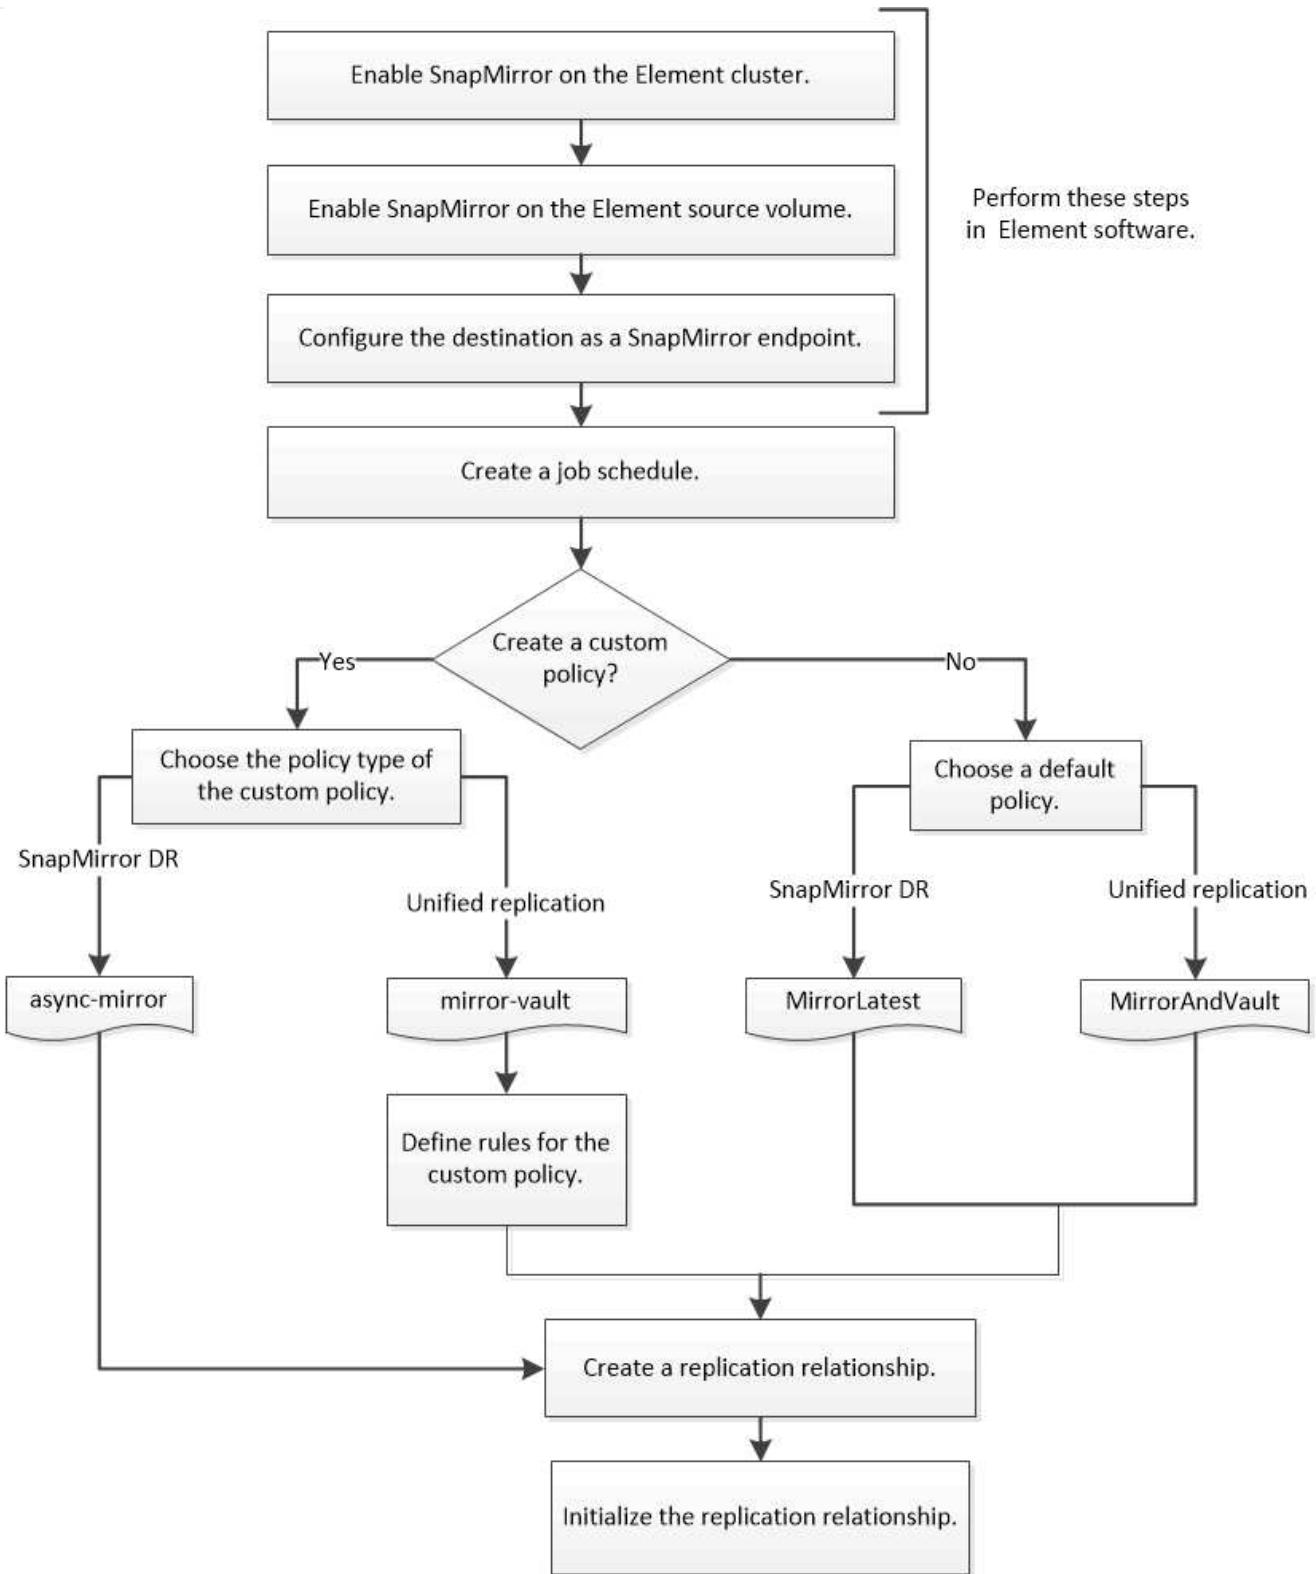

:icons: font

:relative_path: ./element-replication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Whether you are replicating data from Element to ONTAP or from ONTAP to Element, you need to configure a job schedule, specify a policy, and create and initialize the relationship. You can use a default or custom policy.

The workflow assumes that you have completed the prerequisite tasks listed in [Prerequisites](#). For complete background information on SnapMirror policies, including guidance on which policy to use, see [Data protection](#).

= Enable SnapMirror in Element software

= Enable SnapMirror on the Element cluster

:icons: font

:relative_path: ./element-replication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You must enable SnapMirror on the Element cluster before you can create a

replication relationship. You can perform this task in the Element software web UI only.

Before you begin

- The Element cluster must be running NetApp Element software version 10.1 or later.
- SnapMirror can only be enabled for Element clusters used with NetApp ONTAP volumes.

About this task

The Element system comes with SnapMirror disabled by default. SnapMirror is not automatically enabled as part of a new installation or upgrade.

Once enabled, SnapMirror cannot be disabled. You can only disable the SnapMirror feature and restore the default settings by returning the cluster to the factory image.

Steps

1. Click **Clusters > Settings**.
2. Find the cluster-specific settings for SnapMirror.
3. Click **Enable SnapMirror**.

= Enable SnapMirror on the Element source volume

:icons: font

:relative_path: ./element-replication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You must enable SnapMirror on the Element source volume before you can create a replication relationship. You can perform this task in the Element software web UI only.

Before you begin

- You must have enabled SnapMirror on the Element cluster.
- The volume block size must be 512 bytes.
- The volume must not be participating in Element remote replication.
- The volume access type must not be “Replication Target”.

About this task

The procedure below assumes the volume already exists. You can also enable SnapMirror when you create or clone a volume.

Steps

1. Click **Management > Volumes**.
2. Click the button for the volume.
3. In the drop-down menu, select **Edit**.
4. In the **Edit Volume** dialog, select **Enable SnapMirror**.
5. Click **Save Changes**.

= Create a SnapMirror endpoint

:icons: font

```
:relative_path: ./element-replication/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

You must create a SnapMirror endpoint before you can create a replication relationship. You can perform this task in the Element software web UI only.

Before you begin

You must have enabled SnapMirror on the Element cluster.

Steps

1. Click **Data Protection > SnapMirror Endpoints**.
2. Click **Create Endpoint**.
3. In the **Create a New Endpoint** dialog, enter the ONTAP cluster management IP address.
4. Enter the user ID and password of the ONTAP cluster administrator.
5. Click **Create Endpoint**.

= Configure a replication relationship

= Create a replication job schedule

:icons: font

```
:relative_path: ./element-replication/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

Whether you are replicating data from Element to ONTAP or from ONTAP to Element, you need to configure a job schedule, specify a policy, and create and initialize the relationship. You can use a default or custom policy.

You can use the `job schedule cron create` command to create a replication job schedule. The job schedule determines when SnapMirror automatically updates the data protection relationship to which the schedule is assigned.

About this task

You assign a job schedule when you create a data protection relationship. If you do not assign a job schedule, you must update the relationship manually.

Step

1. Create a job schedule:

```
job schedule cron create -name job_name -month month -dayofweek day_of_week  
-day day_of_month -hour hour -minute minute
```

For `-month`, `-dayofweek`, and `-hour`, you can specify `all` to run the job every month, day of the week, and hour, respectively.

Beginning with ONTAP 9.10.1, you can include the Vserver for your job schedule:

```
job schedule cron create -name job_name -vserver Vserver_name -month month  
-dayofweek day_of_week -day day_of_month -hour hour -minute minute
```

The following example creates a job schedule named `my_weekly` that runs on Saturdays at 3:00 a.m.:

```
cluster_dst::> job schedule cron create -name my_weekly -dayofweek  
"Saturday" -hour 3 -minute 0
```

= Customize a replication policy

= Create a custom replication policy

:icons: font

:relative_path: ./element-replication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use a default or custom policy when you create a replication relationship. For a custom unified replication policy, you must define one or more *rules* that determine which Snapshot copies are transferred during initialization and update.

You can create a custom replication policy if the default policy for a relationship is not suitable. You might want to compress data in a network transfer, for example, or modify the number of attempts SnapMirror makes to transfer Snapshot copies.

About this task

The *policy type* of the replication policy determines the type of relationship it supports. The table below shows the available policy types.

Policy type	Relationship type
async-mirror	SnapMirror DR
mirror-vault	Unified replication

Step

1. Create a custom replication policy:

```
snapmirror policy create -vserver SVM -policy policy -type async-  
mirror|mirror-vault -comment comment -tries transfer_tries -transfer-  
priority low|normal -is-network-compression-enabled true|false
```

For complete command syntax, see the man page.

Beginning with ONTAP 9.5, you can specify the schedule for creating a common Snapshot copy schedule for SnapMirror Synchronous relationships by using the *-common-snapshot-schedule* parameter. By default, the common Snapshot copy schedule for SnapMirror Synchronous relationships is one hour. You can specify a value from 30 minutes to two hours for the Snapshot copy schedule for SnapMirror Synchronous relationships.

The following example creates a custom replication policy for SnapMirror DR that enables network compression for data transfers:

```
cluster_dst::> snapmirror policy create -vserver svml -policy  
DR_compressed -type async-mirror -comment "DR with network  
compression enabled" -is-network-compression-enabled true
```

The following example creates a custom replication policy for unified replication:

```
cluster_dst::> snapmirror policy create -vserver svml -policy  
my_unified -type mirror-vault
```

After you finish

For “mirror-vault” policy types, you must define rules that determine which Snapshot copies are transferred during initialization and update.

Use the `snapmirror policy show` command to verify that the SnapMirror policy was created. For complete command syntax, see the man page.

= Define a rule for a policy
:icons: font
:relative_path: ./element-replication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

For custom policies with the “mirror-vault” policy type, you must define at least one rule that determines which Snapshot copies are transferred during initialization and update. You can also define rules for default policies with the “mirror-vault” policy type.

About this task

Every policy with the “mirror-vault” policy type must have a rule that specifies which Snapshot copies to replicate. The rule “bi-monthly”, for example, indicates that only Snapshot copies assigned the SnapMirror label “bi-monthly” should be replicated. You assign the SnapMirror label when you configure Element Snapshot copies.

Each policy type is associated with one or more system-defined rules. These rules are automatically assigned to a policy when you specify its policy type. The table below shows the system-defined rules.

System-defined rule	Used in policy types	Result
sm_created	async-mirror, mirror-vault	A Snapshot copy created by SnapMirror is transferred on initialization and update.
daily	mirror-vault	New Snapshot copies on the source with the SnapMirror label “daily” are transferred on initialization and update.

weekly	mirror-vault	New Snapshot copies on the source with the SnapMirror label “weekly” are transferred on initialization and update.
monthly	mirror-vault	New Snapshot copies on the source with the SnapMirror label “monthly” are transferred on initialization and update.

You can specify additional rules as needed, for default or custom policies. For example:

- For the default MirrorAndVault policy, you might create a rule called “bi-monthly” to match Snapshot copies on the source with the “bi-monthly” SnapMirror label.
- For a custom policy with the “mirror-vault” policy type, you might create a rule called “bi-weekly” to match Snapshot copies on the source with the “bi-weekly” SnapMirror label.

Step

1. Define a rule for a policy:

```
snapmirror policy add-rule -vserver SVM -policy policy_for_rule -snapmirror
-label snapmirror-label -keep retention_count
```

For complete command syntax, see the man page.

The following example adds a rule with the SnapMirror label bi-monthly to the default MirrorAndVault policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy
MirrorAndVault -snapmirror-label bi-monthly -keep 6
```

The following example adds a rule with the SnapMirror label bi-weekly to the custom my_snapvault policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy
my_snapvault -snapmirror-label bi-weekly -keep 26
```

The following example adds a rule with the SnapMirror label app_consistent to the custom Sync policy:

```
cluster_dst::> snapmirror policy add-rule -vserver svml -policy Sync
-snapmirror-label app_consistent -keep 1
```

You can then replicate Snapshot copies from the source cluster that match this SnapMirror label:

```
cluster_src::> snapshot create -vserver vs1 -volume vol1 -snapshot  
snapshot1 -snapmirror-label app_consistent
```

= Create a replication relationship

= Create a relationship from an Element source to an ONTAP destination

:icons: font

:relative_path: ./element-replication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

The relationship between the source volume in primary storage and the destination volume in secondary storage is called a *data protection relationship*. You can use the snapmirror create command to create a data protection relationship from an Element source to an ONTAP destination, or from an ONTAP source to an Element destination.

You can use SnapMirror to replicate Snapshot copies of an Element volume to an ONTAP destination system. In the event of a disaster at the Element site, you can serve data to clients from the ONTAP system, then reactivate the Element source volume when service is restored.

Before you begin

- The Element node containing the volume to be replicated must have been made accessible to ONTAP.
- The Element volume must have been enabled for SnapMirror replication.
- If you are using the “mirror-vault” policy type, a SnapMirror label must have been configured for the Element Snapshot copies to be replicated.

You can perform this task in the Element software web UI only. For more information, see the [Element documentation](#).

About this task

You must specify the Element source path in the form *hostip:/lun/name*, where “lun” is the actual string “lun” and name is the name of the Element volume.

An Element volume is roughly equivalent to an ONTAP LUN. SnapMirror creates a LUN with the name of the Element volume when a data protection relationship between Element software and ONTAP is initialized. SnapMirror replicates data to an existing LUN if the LUN meets the requirements for replicating from Element software to ONTAP.

Replication rules are as follows:

- An ONTAP volume can contain data from one Element volume only.
- You cannot replicate data from an ONTAP volume to multiple Element volumes.

In ONTAP 9.3 and earlier, a destination volume can contain up to 251 Snapshot copies. In ONTAP 9.4 and later, a destination volume can contain up to 1019 Snapshot copies.

Step

- From the destination cluster, create a replication relationship from an Element source to an ONTAP destination:

```
snapmirror create -source-path hostip:/lun/name -destination-path  
SVM:volume|cluster://SVM/volume -type XDP -schedule schedule -policy policy
```

For complete command syntax, see the man page.

The following example creates a SnapMirror DR relationship using the default `MirrorLatest` policy:

```
cluster_dst:> snapmirror create -source-path 10.0.0.11:/lun/0005  
-destination-path svm_backup:volA_dst -type XDP -schedule my_daily  
-policy MirrorLatest
```

The following example creates a unified replication relationship using the default `MirrorAndVault` policy:

```
cluster_dst:> snapmirror create -source-path 10.0.0.11:/lun/0005  
-destination-path svm_backup:volA_dst -type XDP -schedule my_daily  
-policy MirrorAndVault
```

The following example creates a unified replication relationship using the `Unified7year` policy:

```
cluster_dst:> snapmirror create -source-path 10.0.0.11:/lun/0005  
-destination-path svm_backup:volA_dst -type XDP -schedule my_daily  
-policy Unified7year
```

The following example creates a unified replication relationship using the custom `my_unified` policy:

```
cluster_dst:> snapmirror create -source-path 10.0.0.11:/lun/0005  
-destination-path svm_backup:volA_dst -type XDP -schedule my_daily  
-policy my_unified
```

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

= Create a relationship from an ONTAP source to an Element destination

:icons: font

:relative_path: ./element-replication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

Beginning with ONTAP 9.4, you can use SnapMirror to replicate Snapshot copies of a LUN created on an ONTAP source back to an Element destination. You might be

using the LUN to migrate data from ONTAP to Element software.

Before you begin

- The Element destination node must have been made accessible to ONTAP.
- The Element volume must have been enabled for SnapMirror replication.

About this task

You must specify the Element destination path in the form *hostip*:/*lun/name*, where “lun” is the actual string “lun” and name is the name of the Element volume.

Replication rules are as follows:

- The replication relationship must have a policy of type “async-mirror”.

You can use a default or custom policy.

- Only iSCSI LUNs are supported.
- You cannot replicate more than one LUN from an ONTAP volume to an Element volume.
- You cannot replicate a LUN from an ONTAP volume to multiple Element volumes.

Step

1. Create a replication relationship from an ONTAP source to an Element destination:

```
snapmirror create -source-path SVM:volume|cluster://SVM/volume -destination-path hostip:/lun/name -type XDP -schedule schedule -policy policy
```

For complete command syntax, see the man page.

The following example creates a SnapMirror DR relationship using the default `MirrorLatest` policy:

```
cluster_dst::> snapmirror create -source-path svm_1:volA_dst -destination-path 10.0.0.11:/lun/0005 -type XDP -schedule my_daily -policy MirrorLatest
```

The following example creates a SnapMirror DR relationship using the custom `my_mirror` policy:

```
cluster_dst::> snapmirror create -source-path svm_1:volA_dst -destination-path 10.0.0.11:/lun/0005 -type XDP -schedule my_daily -policy my_mirror
```

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

= Initialize a replication relationship
:icons: font
:relative_path: ./element-replication/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/ ./encryption-at-rest/./media/
```

For all relationship types, initialization performs a *baseline transfer*: it makes a Snapshot copy of the source volume, then transfers that copy and all the data blocks it references to the destination volume.

Before you begin

- The Element node containing the volume to be replicated must have been made accessible to ONTAP.
- The Element volume must have been enabled for SnapMirror replication.
- If you are using the “mirror-vault” policy type, a SnapMirror label must have been configured for the Element Snapshot copies to be replicated.

About this task

You must specify the Element source path in the form `hostip:/lun/name`, where “lun” is the actual string “lun” and `name` is the name of the Element volume.

Initialization can be time-consuming. You might want to run the baseline transfer in off-peak hours.

If initialization of a relationship from an ONTAP source to an Element destination fails for any reason, it will continue to fail even after you have corrected the problem (an invalid LUN name, for example). The workaround is as follows:

1. Delete the relationship.
2. Delete the Element destination volume.
3. Create a new Element destination volume.
4. Create and initialize a new relationship from the ONTAP source to the Element destination volume.

Step

1. Initialize a replication relationship:

```
snapmirror initialize -source-path hostip:/lun/name -destination-path  
SVM:volume|cluster://SVM/volume
```

For complete command syntax, see the man page.

The following example initializes the relationship between the source volume 0005 at IP address 10.0.0.11 and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror initialize -source-path  
10.0.0.11:/lun/0005 -destination-path svm_backup:volA_dst
```

= Serve data from a SnapMirror DR destination volume

= Make the destination volume writeable

:icons: font

:relative_path: ./element-replication/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/ ./encryption-at-rest/./media/
```

When disaster disables the primary site for a SnapMirror DR relationship, you can serve data from the destination volume with minimal disruption. You can reactivate the source volume when service is restored at the primary site.

You need to make the destination volume writeable before you can serve data from the volume to clients. You can use the `snapmirror quiesce` command to stop scheduled transfers to the destination, the `snapmirror abort` command to stop ongoing transfers, and the `snapmirror break` command to make the destination writeable.

About this task

You must specify the Element source path in the form `hostip:/lun/name`, where “lun” is the actual string “lun” and name is the name of the Element volume.

Steps

1. Stop scheduled transfers to the destination:

```
snapmirror quiesce -source-path hostip:/lun/name -destination-path  
SVM:volume|cluster://SVM/volume
```

For complete command syntax, see the man page.

The following example stops scheduled transfers between the source volume 0005 at IP address 10.0.0.11 and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror quiesce -source-path 10.0.0.11:/lun/0005  
-destination-path svm_backup:volA_dst
```

2. Stop ongoing transfers to the destination:

```
snapmirror abort -source-path hostip:/lun/name -destination-path  
SVM:volume|cluster://SVM/volume
```

For complete command syntax, see the man page.

The following example stops ongoing transfers between the source volume 0005 at IP address 10.0.0.11 and the destination volume `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror abort -source-path 10.0.0.11:/lun/0005  
-destination-path svm_backup:volA_dst
```

3. Break the SnapMirror DR relationship:

```
snapmirror break -source-path hostip:/lun/name -destination-path  
SVM:volume|cluster://SVM/volume
```

For complete command syntax, see the man page.

The following example breaks the relationship between the source volume 0005 at IP address 10.0.0.11 and the destination volume volA_dst on svm_backup and the destination volume volA_dst on svm_backup:

```
cluster_dst::> snapmirror break -source-path 10.0.0.11:/lun/0005  
-destination-path svm_backup:volA_dst
```

= Configure the destination volume for data access
:icons: font
:relative_path: ./element-replication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

After making the destination volume writeable, you must configure the volume for data access. SAN hosts can access the data from the destination volume until the source volume is reactivated.

1. Map the Element LUN to the appropriate initiator group.
2. Create iSCSI sessions from the SAN host initiators to the SAN LIFs.
3. On the SAN client, perform a storage re-scan to detect the connected LUN.

= Reactivate the original source volume
:icons: font
:relative_path: ./element-replication/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can reestablish the original data protection relationship between the source and destination volumes when you no longer need to serve data from the destination.

About this task

The procedure below assumes that the baseline in the original source volume is intact. If the baseline is not intact, you must create and initialize the relationship between the volume you are serving data from and the original source volume before performing the procedure.

You must specify the Element source path in the form *hostip*:/lun/*name*, where “lun” is the actual string “lun” and *name* is the name of the Element volume.

Beginning with ONTAP 9.4, Snapshot copies of a LUN created while you are serving data from the ONTAP destination are automatically replicated when the Element source is reactivated.

Replication rules are as follows:

- Only iSCSI LUNs are supported.
- You cannot replicate more than one LUN from an ONTAP volume to an Element volume.
- You cannot replicate a LUN from an ONTAP volume to multiple Element volumes.

Steps

1. Delete the original data protection relationship:

```
snapmirror delete -source-path SVM:volume|cluster://SVM/volume -destination
```

```
-path hostip:/lun/name -policy policy
```

For complete command syntax, see the man page.

The following example deletes the relationship between the original source volume, 0005 at IP address 10.0.0.11, and the volume you are serving data from, `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror delete -source-path 10.0.0.11:/lun/0005  
-policy MirrorLatest -destination-path svm_backup:volA_dst
```

2. Reverse the original data protection relationship:

```
snapmirror resync -source-path SVM:volume|cluster://SVM/volume -destination  
-path hostip:/lun/name -policy policy
```

For complete command syntax, see the man page.

Although `resync` does not require a baseline transfer, it can be time-consuming. You might want to run the `resync` in off-peak hours.

The following example reverses the relationship between the original source volume, 0005 at IP address 10.0.0.11, and the volume you are serving data from, `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path svm_backup:volA_dst  
-destination-path 10.0.0.11:/lun/0005 -policy MirrorLatest
```

3. Update the reversed relationship:

```
snapmirror update -source-path SVM:volume|cluster://SVM/volume -destination  
-path hostip:/lun/name
```

For complete command syntax, see the man page.

The command fails if a common Snapshot copy does not exist on the source and destination. Use `snapmirror initialize` to re-initialize the relationship.

The following example updates the relationship between the volume you are serving data from, `volA_dst` on `svm_backup`, and the original source volume, 0005 at IP address 10.0.0.11:

```
cluster_dst::> snapmirror update -source-path svm_backup:volA_dst  
-destination-path 10.0.0.11:/lun/0005
```

4. Stop scheduled transfers for the reversed relationship:

```
snapmirror quiesce -source-path SVM:volume|cluster://SVM/volume  
-destination-path hostip:/lun/name
```

For complete command syntax, see the man page.

The following example stops scheduled transfers between the volume you are serving data from, `volA_dst` on `svm_backup`, and the original source volume, `0005` at IP address `10.0.0.11`:

```
cluster_dst::> snapmirror quiesce -source-path svm_backup:volA_dst  
-destination-path 10.0.0.11:/lun/0005
```

5. Stop ongoing transfers for the reversed relationship:

```
snapmirror abort -source-path SVM:volume|cluster://SVM/volume -destination  
-path hostip:/lun/name
```

For complete command syntax, see the man page.

The following example stops ongoing transfers between the volume you are serving data from, `volA_dst` on `svm_backup`, and the original source volume, `0005` at IP address `10.0.0.11`:

```
cluster_dst::> snapmirror abort -source-path svm_backup:volA_dst  
-destination-path 10.0.0.11:/lun/0005
```

6. Break the reversed relationship:

```
snapmirror break -source-path SVM:volume|cluster://SVM/volume -destination  
-path hostip:/lun/name
```

For complete command syntax, see the man page.

The following example breaks the relationship between the volume you are serving data from, `volA_dst` on `svm_backup`, and the original source volume, `0005` at IP address `10.0.0.11`:

```
cluster_dst::> snapmirror break -source-path svm_backup:volA_dst  
-destination-path 10.0.0.11:/lun/0005
```

7. Delete the reversed data protection relationship:

```
snapmirror delete -source-path SVM:volume|cluster://SVM/volume -destination  
-path hostip:/lun/name -policy policy
```

For complete command syntax, see the man page.

The following example deletes the reversed relationship between the original source volume, `0005` at IP address `10.0.0.11`, and the volume you are serving data from, `volA_dst` on `svm_backup`:

```
cluster_src::> snapmirror delete -source-path svm_backup:volA_dst  
-destination-path 10.0.0.11:/lun/0005 -policy MirrorLatest
```

8. Reestablish the original data protection relationship:

```
snapmirror resync -source-path hostip:/lun/name -destination-path  
SVM:volume|cluster://SVM/volume
```

For complete command syntax, see the man page.

The following example reestablishes the relationship between the original source volume, 0005 at IP address 10.0.0.11, and the original destination volume, `volA_dst` on `svm_backup`:

```
cluster_dst::> snapmirror resync -source-path 10.0.0.11:/lun/0005  
-destination-path svm_backup:volA_dst
```

After you finish

Use the `snapmirror show` command to verify that the SnapMirror relationship was created. For complete command syntax, see the man page.

= Update a replication relationship manually

:icons: font

:relative_path: ./element-replication/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You might need to update a replication relationship manually if an update fails because of a network error.

About this task

You must specify the Element source path in the form `hostip:/lun/name`, where “lun” is the actual string “lun” and name is the name of the Element volume.

Steps

1. Update a replication relationship manually:

```
snapmirror update -source-path hostip:/lun/name -destination-path  
SVM:volume|cluster://SVM/volume
```

For complete command syntax, see the man page.

The command fails if a common Snapshot copy does not exist on the source and destination. Use `snapmirror initialize` to re-initialize the relationship.

The following example updates the relationship between the source volume 0005 at IP address 10.0.0.11 and the destination volume `volA_dst` on `svm_backup`:

```
cluster_src::> snapmirror update -source-path 10.0.0.11:/lun/0005  
-destination-path svm_backup:volA_dst
```

= Resynchronize a replication relationship

:icons: font

:relative_path: ./element-replication/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

You need to resynchronize a replication relationship after you make a destination volume writeable, after an update fails because a common Snapshot copy does not exist on the source and destination volumes, or if you want to change the replication policy for the relationship.

About this task

Although resync does not require a baseline transfer, it can be time-consuming. You might want to run the resync in off-peak hours.

You must specify the Element source path in the form *hostip:/lun/name*, where “lun” is the actual string “lun” and name is the name of the Element volume.

Step

1. Resync the source and destination volumes:

```
snapmirror resync -source-path hostip:/lun/name -destination-path  
SVM:volume|cluster://SVM/volume -type XDP -schedule schedule -policy policy
```

For complete command syntax, see the man page.

The following example resyncs the relationship between the source volume 0005 at IP address 10.0.0.11 and the destination volume volA_dst on svm_backup:

```
cluster_dst::> snapmirror resync -source-path 10.0.0.11:/lun/0005  
-policy MirrorLatest -destination-path svm_backup:volA_dst
```

```

The topics in this section show you how to manage cluster health and performance with System Manager in ONTAP 9.7 and later releases.

The System Manager Dashboard provides the following performance information:

- **Health:** You can monitor the health of a cluster. Alerts are shown when problems arise.
- **Capacity:** System Manager shows you the available capacity on the cluster.
- **Performance:** You can monitor how well the cluster is performing, based on latency, IOPS, and throughput. The metrics are graphed every 15 seconds by hour, day, week, month, or year.
- **Network:** You can view how the network is configured with hosts and storage objects. You can view the number of ports that are available and the interfaces and storage VMs that are associated with them.

= View performance on cluster dashboard

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/.media/

Use the dashboard to make informed decisions about workloads you might want to add or move. You can also look at peak usage times to plan for potential changes.

The performance values refresh every 3 seconds and the performance graph refreshes every 15 seconds.

Steps

1. Click **Dashboard**.
2. Under **Performance**, select the interval.

= Identify hot volumes and other objects

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/.media/

Accelerate your cluster performance by identifying the frequently accessed volumes (hot volumes) and data (hot objects).

Steps

1. Click **Storage > Volumes**.
2. Filter the IOPS, latency, and throughput columns to view the frequently accessed volumes and data.

= Modify QoS

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/.media/

Beginning with ONTAP 9.8, when you provision storage, QoS is enabled by default. You can disable QoS or choose a custom QoS policy during the provisioning process. You can also modify QoS after your storage has been provisioned.

Steps

1. In System Manager, click **Storage** and select **Volumes**.
2. Next to the volume for which you want to modify QoS, click  and select **Edit**.

= Monitor cluster performance using System Manager

:toc: macro

:toplevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

You can monitor cluster performance by viewing information about your system on the System Manager Dashboard.

The Dashboard displays information about important alerts and notifications, the efficiency and capacity of storage tiers and volumes, the nodes that are available in a cluster, the status of the nodes in an HA pair, the most active applications and objects, and the performance metrics of a cluster or a node.

The Dashboard lets you determine the following information:

- **Health:** How healthy is the cluster?
- **Capacity:** What capacity is available on the cluster?
- **Performance:** How well is the cluster performing, based on latency, IOPS, and throughput?
- **Network:** How is the network configured with hosts and storage objects, such as ports, interfaces, and storage VMs?

In the Health and Capacity overviews, you can click  to view additional information and perform tasks.

In the Performance overview, you can view metrics based on the hour, the day, the week, the month, or the year.

In the Network overview, the number of each object in the network is displayed (for example, "8 NVMe/FC ports"). You can click on the numbers to view details about each network object.

= Performance monitoring setup with the CLI

= Performance monitoring overview

:icons: font

:relative_path: ./performance-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

You can quickly install and configure Active IQ Unified Manager (formerly OnCommand Unified Manager), perform basic monitoring tasks, and identify performance issues.

You should use these procedure to monitor cluster performance, if the following assumptions apply to your situation:

- You want to use best practices, not explore every available option.
- You want to install Unified Manager by using a virtual appliance, instead of a Linux or Windows-based installation.
- You're willing to use a static configuration rather than DHCP to install the software.
- You are a cluster administrator with the "admin" role.

Related information

If these assumptions are not correct for your situation, you should see the following resources:

- [Active IQ Unified Manager 9.8 Installation](#)

= Performance monitoring

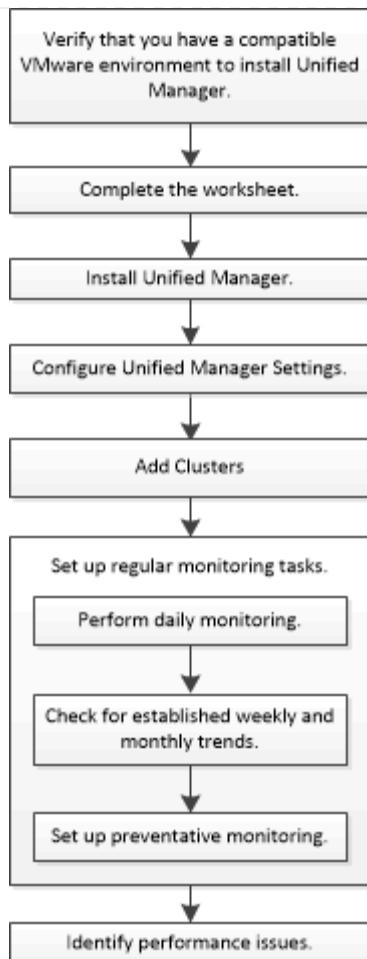

= Performance monitoring workflow

:icons: font

:relative_path: ./performance-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

Monitoring cluster performance involves installing Active IQ Unified Manager software, setting up basic monitoring tasks, and identifying performance issues.

= Verify that your VMware environment is supported

:icons: font

:relative_path: ./performance-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

For successful installation of Active IQ Unified Manager, you must verify that your VMware environment meets the necessary requirements.

Steps

1. Verify that your VMware infrastructure meets the sizing requirements for the installation of Unified Manager.
2. Go to the Interoperability Matrix to verify that you have a supported combination of the following components:
 - ONTAP version
 - ESXi operating system version
 - VMware vCenter Server version
 - VMware Tools version
 - Browser type and version

The [Interoperability Matrix](#) lists the supported configurations for Unified Manager.

3. Click the configuration name for the selected configuration.

Details for that configuration are displayed in the Configuration Details window.

4. Review the information in the following tabs:

- Notes

Lists important alerts and information that are specific to your configuration.

- Policies and Guidelines

Provides general guidelines for all configurations.

= Active IQ Unified Manager worksheet

:icons: font

:relative_path: ./performance-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

Before you install, configure, and connect Active IQ Unified Manager, you should have specific information about your environment readily available. You can record the information in the worksheet.

== Unified Manager installation information

Virtual machine on which software is deployed	Your value
ESXi server IP address	
Host fully qualified domain name	
Host IP address

= Install Active IQ Unified Manager

= Download and deploy Active IQ Unified Manager

:icons: font

:relative_path: ./performance-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..../media/

To install the software, you must download the virtual appliance (VA) installation file and then use a VMware vSphere Client to deploy the file to a VMware ESXi server. The VA is available in an OVA file.

Steps

1. Go to the **NetApp Support Site Software Download** page and locate Active IQ Unified Manager.
<https://mysupport.netapp.com/products/index.html>
2. Select **VMware vSphere** in the **Select Platform** drop-down menu and click **Go!**
3. Save the OVA file to a local or network location that is accessible to your VMware vSphere Client.
4. In VMware vSphere Client, click **File > Deploy OVF Template**.
5. Locate the OVA file and use the wizard to deploy the virtual appliance on the ESXi server.

You can use the **Properties** tab in the wizard to enter your static configuration information.

6. Power on the VM.
7. Click the **Console** tab to view the initial boot process.
8. Follow the prompt to install VMware Tools on the VM.
9. Configure the time zone.
10. Enter a maintenance user name and password.
11. Go to the URL displayed by the VM console.

= Configure initial Active IQ Unified Manager settings

```
:icons: font  
:relative_path: ./performance-config/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

The Active IQ Unified Manager Initial Setup dialog box appears when you first access the web UI, which enables you to configure some initial settings and to add clusters.

Steps

1. Accept the default AutoSupport enabled setting.
2. Enter the NTP server details, the maintenance user email address, the SMTP server host name, and additional SMTP options, and then click **Save**.

After you finish

When the initial setup is complete, the Cluster Data Sources page is displayed where you can add the cluster details.

= Specify the clusters to be monitored

```
:icons: font  
:relative_path: ./performance-config/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

You must add a cluster to an Active IQ Unified Manager server to monitor the cluster, view the cluster discovery status, and monitor its performance.

What you'll need

- You must have the following information:
 - Host name or cluster-management IP address

The host name is the fully qualified domain name (FQDN) or short name that Unified Manager uses to connect to the cluster. This host name must resolve to the cluster-management IP address.
 - ONTAP administrator user name and password
 - Type of protocol (HTTP or HTTPS) that can be configured on the cluster and the port number of the cluster
- You must have the Application Administrator or Storage Administrator role.
- The ONTAP administrator must have the ONTAPI and SSH administrator roles.
- The Unified Manager FQDN must be able to ping ONTAP.

You can verify this by using the ONTAP command `ping -node node_name -destination Unified_Manager_FQDN`.

About this task

For a MetroCluster configuration, you must add both the local and remote clusters, and the clusters must be configured correctly.

Steps

1. Click **Configuration > Cluster Data Sources**.
2. From the Clusters page, click **Add**.
3. In the **Add Cluster** dialog box, specify the required values, such as the host name or IP address (IPv4 or IPv6) of the cluster, user name, password, protocol for communication, and port number.

By default, the HTTPS protocol is selected.

You can change the cluster-management IP address from IPv6 to IPv4 or from IPv4 to IPv6. The new IP address is reflected in the cluster grid and the cluster configuration page after the next monitoring cycle finishes.

4. Click **Add**.
5. If HTTPS is selected, perform the following steps:
 - a. In the **Authorize Host** dialog box, click **View Certificate** to view the certificate information about the cluster.
 - b. Click **Yes**.

Unified Manager checks the certificate only when the cluster is initially added, but does not check it for each API call to ONTAP.

If the certificate has expired, you cannot add the cluster. You must renew the SSL certificate and then add the cluster.

6. Optional: View the cluster discovery status:

- a. Review the cluster discovery status from the **Cluster Setup** page.

The cluster is added to the Unified Manager database after the default monitoring interval of approximately 15 minutes.

= Set up basic monitoring tasks

= Perform daily monitoring

:icons: font

:relative_path: ./performance-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

You can perform daily monitoring to ensure that you do not have any immediate performance issues that require attention.

Steps

1. From the Active IQ Unified Manager UI, go to the **Event Inventory** page to view all current and obsolete events.
2. From the **View** option, select **Active Performance Events** and determine what action is required.

= Use weekly and monthly performance trends to identify performance issues

:icons: font

:relative_path: ./performance-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

Identifying performance trends can assist you in identifying whether the cluster is being overused or underused by analyzing volume latency. You can use similar steps to identify CPU, network, or other system bottlenecks.

Steps

1. Locate the volume that you suspect is being underused or overused.
2. On the **Volume Details** tab, click **30 d** to display the historical data.
3. In the "Break down data by" drop-down menu, select **Latency**, and then click **Submit**.
4. Deselect **Aggregate** in the cluster components comparison chart, and then compare the cluster latency with the volume latency chart.
5. Select **Aggregate** and deselect all other components in the cluster components comparison chart, and then compare the aggregate latency with the volume latency chart.
6. Compare the reads/writes latency chart to the volume latency chart.
7. Determine whether client application loads have caused a workload contention and rebalance workloads as needed.
8. Determine whether the aggregate is overused and causing contention and rebalance workloads as needed.

= Use performance thresholds to generate event notifications

= Set performance thresholds

```
:icons: font
:relative_path: ./performance-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

You can set performance thresholds to monitor critical performance issues. User-defined thresholds trigger a warning or a critical event notification when the system approaches or exceeds the defined threshold.

Steps

1. Create the Warning and Critical event thresholds:
 - a. Select **Configuration > Performance Thresholds**.
 - b. Click **Create**.
 - c. Select the object type and specify a name and description of the policy.
 - d. Select the object counter condition and specify the limit values that define Warning and Critical events.
 - e. Select the duration of time that the limit values must be breached for an event to be sent, and then click **Save**.
2. Assign the threshold policy to the storage object.
 - a. Go to the Inventory page for the same cluster object type that you previously selected and choose the **Performance** from the View option.
 - b. Select the object to which you want to assign the threshold policy, and then click **Assign Threshold Policy**.
 - c. Select the policy you previously created, and then click **Assign Policy**.

Example

You can set user-defined thresholds to learn about critical performance issues. For example, if you have a Microsoft Exchange Server and you know that it crashes if volume latency exceeds 20 milliseconds, you can set a warning threshold at 12 milliseconds and a critical threshold at 15 milliseconds. With this threshold setting, you can receive notifications when the volume latency exceeds the limit.

Object Counter Condition*	Average Latency ms/op	 Warning	ms/op	 Critical	ms/op
		12		15	

= Configure alert settings

```
:icons: font
:relative_path: ./performance-config/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/
```

You can specify which events from Active IQ Unified Manager trigger alerts, the email recipients for those alerts, and the frequency for the alerts.

What you'll need

You must have the Application Administrator role.

About this task

You can configure unique alert settings for the following types of performance events:

- Critical events triggered by breaches of user-defined thresholds
- Warning events triggered by breaches of user-defined thresholds, system-defined thresholds, or dynamic thresholds

By default, email alerts are sent to Unified Manager admin users for all new events. You can have email alerts sent to other users by adding those users' email addresses.

To disable alerts from being sent for certain types of events, you must clear all of the check boxes in an event category. This action does not stop events from appearing in the user interface.

Steps

1. In the left navigation pane, select **Storage Management > Alert Setup**.

The Alert Setup page is displayed.

2. Click **Add** and configure the appropriate settings for each of the event types.

To have email alerts sent to multiple users, enter a comma between each email address.

3. Click **Save**.

= Identify performance issues in Active IQ Unified Manager

:icons: font

:relative_path: ./performance-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

If a performance event occurs, you can locate the source of the issue within Active IQ Unified Manager and use other tools to fix it. You might receive an email notification of an event or notice the event during daily monitoring.

Steps

1. Click the link in the email notification, which takes you directly to the storage object having a performance event.

If you...	Then...
Receive an email notification of an event	Click the link to go directly to the event details page.
Notice the event while analyzing the Event Inventory page	Select the event to go directly to the event details page.

2. If the event has crossed a system-defined threshold, follow the suggested actions in the UI to troubleshoot the issue.
3. If the event has crossed a user-defined threshold, analyze the event to determine if you need to take action.
4. If the issue persists, check the following settings:
 - Protocol settings on the storage system

- Network settings on any Ethernet or fabric switches
 - Network settings on the storage system
 - Disk layout and aggregate metrics on the storage system
5. If the issue persists, contact technical support for assistance.

= Use Active IQ Digital Advisor to view system performance

:icons: font

:relative_path: ./performance-config/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

For any ONTAP system that sends AutoSupport telemetry to NetApp, you can view extensive performance and capacity data. Active IQ shows system performance over a longer period than you can see in System Manager.

You can view graphs of CPU utilization, latency, IOPS, IOPS by protocol, and network throughput. You can also download this data in .csv format for analysis in other tools.

In addition to this performance data, Active IQ can show you storage efficiency by workload and compare that efficiency to the expected efficiency for that type of workload. You can view capacity trends and see an estimate of how much additional storage you might need to add in a given timeframe

- Storage Efficiency is available at the customer, cluster, and node level on the left-hand-side of the main dashboard.
- Performance is available at the cluster and node level on the left-hand-side of the main dashboard.

:icons: font
:relative_path: ./performance-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

You must add a cluster to an Active IQ Unified Manager server to monitor the cluster, view the cluster discovery status, and monitor its performance.

What you'll need

- You must have the following information:
 - Host name or cluster-management IP address

The host name is the fully qualified domain name (FQDN) or short name that Unified Manager uses to connect to the cluster. This host name must resolve to the cluster-management IP address.

The cluster-management IP address must be the cluster-management LIF of the administrative storage virtual machine (SVM). If you use a node-management LIF, the operation fails.
 - ONTAP administrator user name and password
 - Type of protocol (HTTP or HTTPS) that can be configured on the cluster and the port number of the cluster
- You must have the Application Administrator or Storage Administrator role.
- The ONTAP administrator must have the ONTAPI and SSH administrator roles.
- The Unified Manager FQDN must be able to ping ONTAP.

You can verify this by using the ONTAP command `ping -node node_name -destination Unified_Manager_FQDN`.

About this task

For a MetroCluster configuration, you must add both the local and remote clusters, and the clusters must be configured correctly.

Steps

1. Click **Configuration > Cluster Data Sources**.
2. From the Clusters page, click **Add**.
3. In the **Add Cluster** dialog box, specify the required values, such as the host name or IP address (IPv4 or IPv6) of the cluster, user name, password, protocol for communication, and port number.

By default, the HTTPS protocol is selected.

You can change the cluster-management IP address from IPv6 to IPv4 or from IPv4 to IPv6. The new IP address is reflected in the cluster grid and the cluster configuration page after the next monitoring cycle finishes.

4. Click **Add**.
5. If HTTPS is selected, perform the following steps:
 - a. In the **Authorize Host** dialog box, click **View Certificate** to view the certificate information about the cluster.

b. Click **Yes**.

Unified Manager checks the certificate only when the cluster is initially added, but does not check it for each API call to ONTAP.

If the certificate has expired, you cannot add the cluster. You must renew the SSL certificate and then add the cluster.

6. **Optional:** View the cluster discovery status:

a. Review the cluster discovery status from the **Cluster Setup** page.

The cluster is added to the Unified Manager database after the default monitoring interval of approximately 15 minutes.

= Set up basic monitoring tasks

= Perform daily monitoring

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

You can perform daily monitoring to ensure that you do not have any immediate performance issues that require attention.

Steps

1. From the Active IQ Unified Manager UI, go to the **Event Inventory** page to view all current and obsolete events.
2. From the **View** option, select **Active Performance Events** and determine what action is required.

= Use weekly and monthly performance trends to identify performance issues

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

Identifying performance trends can assist you in identifying whether the cluster is being overused or underused by analyzing volume latency. You can use similar steps to identify CPU, network, or other system bottlenecks.

Steps

1. Locate the volume that you suspect is being underused or overused.
2. On the **Volume Details** tab, click **30 d** to display the historical data.
3. In the "Break down data by" drop-down menu, select **Latency**, and then click **Submit**.
4. Deselect **Aggregate** in the cluster components comparison chart, and then compare the cluster latency with the volume latency chart.
5. Select **Aggregate** and deselect all other components in the cluster components comparison chart, and then compare the aggregate latency with the volume latency chart.
6. Compare the reads/writes latency chart to the volume latency chart.
7. Determine whether client application loads have caused a workload contention and rebalance

workloads as needed.

8. Determine whether the aggregate is overused and causing contention and rebalance workloads as needed.

= Use performance thresholds to generate event notifications

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

Events are notifications that the Active IQ Unified Manager generates automatically when a predefined condition occurs, or when a performance counter value crosses a threshold. Events help you identify performance issues in the clusters you are monitoring. You can configure alerts to send email notification automatically when events of certain severity types occur.

= Set performance thresholds

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

You can set performance thresholds to monitor critical performance issues. User-defined thresholds trigger a warning or a critical event notification when the system approaches or exceeds the defined threshold.

Steps

1. Create the Warning and Critical event thresholds:
 - a. Select **Configuration > Performance Thresholds**.
 - b. Click **Create**.
 - c. Select the object type and specify a name and description of the policy.
 - d. Select the object counter condition and specify the limit values that define Warning and Critical events.
 - e. Select the duration of time that the limit values must be breached for an event to be sent, and then click **Save**.
2. Assign the threshold policy to the storage object.
 - a. Go to the Inventory page for the same cluster object type that you previously selected and choose the **Performance** from the View option.
 - b. Select the object to which you want to assign the threshold policy, and then click **Assign Threshold Policy**.
 - c. Select the policy you previously created, and then click **Assign Policy**.

Example

You can set user-defined thresholds to learn about critical performance issues. For example, if you have a Microsoft Exchange Server and you know that it crashes if volume latency exceeds 20 milliseconds, you can set a warning threshold at 12 milliseconds and a critical threshold at 15 milliseconds. With this threshold setting, you can receive notifications when the volume latency exceeds the limit.

= Add alerts

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can configure alerts to notify you when a particular event is generated. You can configure alerts for a single resource, for a group of resources, or for events of a particular severity type. You can specify the frequency with which you want to be notified and associate a script to the alert.

What you'll need

- You must have configured notification settings such as the user email address, SMTP server, and SNMP trap host to enable the Active IQ Unified Manager server to use these settings to send notifications to users when an event is generated.
- You must know the resources and events for which you want to trigger the alert, and the user names or email addresses of the users that you want to notify.
- If you want to have a script execute based on the event, you must have added the script to Unified Manager by using the Scripts page.
- You must have the Application Administrator or Storage Administrator role.

About this task

You can create an alert directly from the Event details page after receiving an event in addition to creating an alert from the Alert Setup page, as described here.

Steps

1. In the left navigation pane, click **Storage Management > Alert Setup**.
2. In the **Alert Setup** page, click **Add**.
3. In the **Add Alert** dialog box, click **Name**, and enter a name and description for the alert.
4. Click **Resources**, and select the resources to be included in or excluded from the alert.

You can set a filter by specifying a text string in the **Name contains** field to select a group of resources. Based on the text string that you specify, the list of available resources displays only those resources that match the filter rule. The text string that you specify is case-sensitive.

If a resource conforms to both the include and exclude rules that you have specified, the exclude rule takes precedence over the include rule, and the alert is not generated for events related to the excluded resource.

5. Click **Events**, and select the events based on the event name or event severity type for which you want to trigger an alert.

To select more than one event, press the Ctrl key while you make your selections.

6. Click **Actions**, and select the users that you want to notify, choose the notification frequency, choose whether an SNMP trap will be sent to the trap receiver, and assign a script to be executed when an alert is generated.

If you modify the email address that is specified for the user and reopen the alert for editing, the Name field appears blank because the modified email address is no longer mapped to the user that was previously selected. Also, if you modified the email address of the selected user from the Users page, the modified email address is not updated for the selected user.

You can also choose to notify users through SNMP traps.

7. Click **Save**.

Example of adding an alert

This example shows how to create an alert that meets the following requirements:

- Alert name: HealthTest
- Resources: includes all volumes whose name contains "abc" and excludes all volumes whose name contains "xyz"
- Events: includes all critical health events
- Actions: includes "sample@domain.com", a "Test" script, and the user has to be notified every 15 minutes

Perform the following steps in the Add Alert dialog box:

1. Click **Name**, and enter **HealthTest** in the **Alert Name** field.
2. Click **Resources**, and in the Include tab, select **Volumes** from the drop-down list.
 - a. Enter **abc** in the **Name contains** field to display the volumes whose name contains "abc".
 - b. Select **<<All Volumes whose name contains 'abc'>>** from the Available Resources area, and move it to the Selected Resources area.
 - c. Click **Exclude**, and enter **xyz** in the **Name contains** field, and then click **Add**.
3. Click **Events**, and select **Critical** from the Event Severity field.
4. Select **All Critical Events** from the Matching Events area, and move it to the Selected Events area.
5. Click **Actions**, and enter sample@domain.com in the Alert these users field.
6. Select **Remind every 15 minutes** to notify the user every 15 minutes.

You can configure an alert to repeatedly send notifications to the recipients for a specified time. You should determine the time from which the event notification is active for the alert.

7. In the Select Script to Execute menu, select **Test** script.
8. Click **Save**.

= Identify performance issues in Active IQ Unified Manager

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

If a performance event occurs, you can locate the source of the issue within Active IQ Unified Manager and use other tools to fix it. You might receive an email notification of an event or notice the event during daily monitoring.

Steps

1. Click the link in the email notification, which takes you directly to the storage object having a performance event.

If you...	Then...
Receive an email notification of an event	Click the link to go directly to the event details page.
Notice the event while analyzing the Event Inventory page	Select the event to go directly to the event details page.

2. If the event has crossed a system-defined threshold, follow the suggested actions in the UI to troubleshoot the issue.
3. If the event has crossed a user-defined threshold, analyze the event to determine if you need to take action.
4. If the issue persists, check the following settings:
 - Protocol settings on the storage system
 - Network settings on any Ethernet or fabric switches
 - Network settings on the storage system
 - Disk layout and aggregate metrics on the storage system
5. If the issue persists, contact technical support for assistance.

= Use Active IQ Digital Advisor to view system performance

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

For any ONTAP system that sends AutoSupport telemetry to NetApp, you can view extensive performance and capacity data. Active IQ shows system performance over a longer period than you can see in System Manager.

You can view graphs of CPU utilization, latency, IOPS, IOPS by protocol, and network throughput. You can also download this data in .csv format for analysis in other tools.

In addition to this performance data, Active IQ can show you storage efficiency by workload and compare that efficiency to the expected efficiency for that type of workload. You can view capacity trends and see an estimate of how much additional storage you might need to add in a given timeframe

- Storage Efficiency is available at the customer, cluster, and node level on the left-hand-side of the main dashboard.
- Performance is available at the cluster and node level on the left-hand-side of the main dashboard.

Active IQ Web Portal

= Manage performance issues

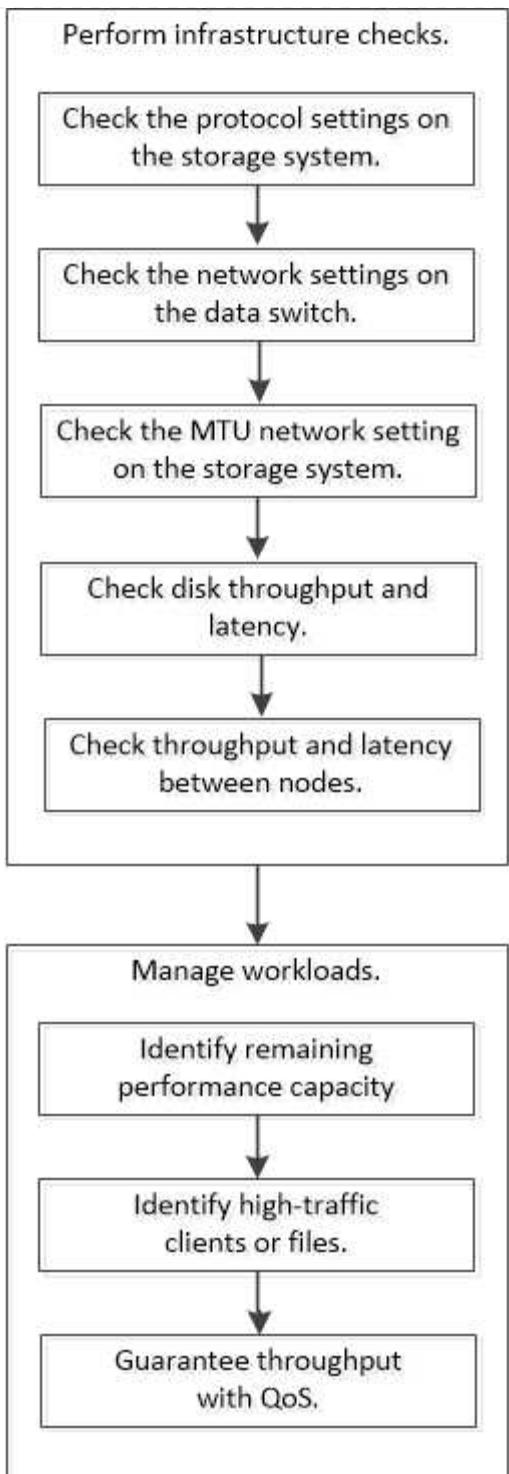

= Performance management workflow

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

Once you have identified a performance issue, you can conduct some basic diagnostic checks of your infrastructure to rule out obvious configuration errors. If those don't pinpoint the problem, you can start looking at workload management issues.

= Perform basic infrastructure checks

= Check protocol settings on the storage system

= Check the NFS TCP maximum transfer size

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

For NFS, you can check whether the TCP maximum transfer size for reads and

writes might be causing a performance issue. If you think the size is slowing performance, you can increase it.

What you'll need

- You must have cluster administrator privileges to perform this task.
- You must use advanced privilege level commands for this task.

Steps

1. Change to the advanced privilege level:

```
set -privilege advanced
```

2. Check the TCP maximum transfer size:

```
vserver nfs show -vserver vserver_name -instance
```

3. If the TCP maximum transfer size is too small, increase the size:

```
vserver nfs modify -vserver vserver_name -tcp-max-xfer-size integer
```

4. Return to the administrative privilege level:

```
set -privilege admin
```

Example

The following example changes the TCP maximum transfer size of SVM1 to 1048576:

```
cluster1::*: vserver nfs modify -vserver SVM1 -tcp-max-xfer-size  
1048576
```

= Check the iSCSI TCP read/write size

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

For iSCSI, you can check the TCP read/write size to determine if the size setting is creating a performance issue. If the size is the source of an issue, you can correct it.

What you'll need

Advanced privilege level commands are required for this task.

Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Check the TCP window size setting:

```
vserver iscsi show -vserver vserver_name -instance
```

3. Modify the TCP window size setting:

```
vserver iscsi modify -vserver vserver_name -tcp-window-size integer
```

4. Return to administrative privilege:

```
set -privilege admin
```

Example

The following example changes the TCP window size of SVM1 to 131,400 bytes:

```
cluster1::*> vserver iscsi modify -vserver vs1 -tcp-window-size 131400
```

= Check the CIFS multiplex settings

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

If slow CIFS network performance causes a performance issue, you can modify the multiplex settings to improve and correct it.

Steps

1. Check the CIFS multiplex setting:

```
vserver cifs options show -vserver -vserver_name -instance
```

2. Modify the CIFS multiplex setting:

```
vserver cifs options modify -vserver -vserver_name -max-mpx integer
```

Example

The following example changes the maximum multiplex count on SVM1 to 255:

```
cluster1::> vserver cifs options modify -vserver SVM1 -max-mpx 255
```

= Check the FC adapter port speed

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

The adapter target port speed should match the speed of the device to which it connects, to optimize performance. If the port is set to autonegotiation, it can take longer to reconnect after a takeover and giveback or other interruption.

What you'll need

All LIFs that use this adapter as their home port must be offline.

Steps

1. Take the adapter offline:

```
network fcp adapter modify -node nodename -adapter adapter -state down
```

2. Check the maximum speed of the port adapter:

```
fcp adapter show -instance
```

3. Change the port speed, if necessary:

```
network fcp adapter modify -node nodename -adapter adapter -speed {1|2|4|8|10|16|auto}
```

4. Bring the adapter online:

```
network fcp adapter modify -node nodename -adapter adapter -state up
```

5. Bring all the LIFs on the adapter online:

```
network interface modify -vserver * -lif * { -home-node node1 -home-port e0c } -status-admin up
```

Example

The following example changes the port speed of adapter 0d on node1 to 2 Gbps:

```
cluster1::> network fcp adapter modify -node node1 -adapter 0d -speed 2
```

= Check the network settings on the data switches

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

Although you must maintain the same MTU settings on your clients, servers and storage systems (that is, network endpoints), intermediate network devices such as NICs and switches should be set to their maximum MTU values to ensure that performance is not impacted.

For best performance, all components in the network must be able to forward jumbo frames (9000 bytes IP, 9022 bytes including Ethernet). Data switches should be set to at least 9022 bytes, but a typical value of 9216 is possible with most switches.

Procedure

For data switches, check that the MTU size is set to 9022 or higher.

For more information, see the switch vendor documentation.

= Check the MTU network setting on the storage system

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can change the network settings on the storage system if they are not the same as on the client or other network endpoints. Whereas the management network MTU setting is set to 1500, the data network MTU size should be 9000.

== About this task

All ports within a broadcast-domain have the same MTU size, with the exception of the e0M port handling management traffic. If the port is part of a broadcast-domain, use the broadcast-domain modify command to change the MTU for all ports within the modified broadcast-domain.

Note that intermediate network devices such as NICs and data switches can be set to higher MTU sizes than network endpoints. For more information, see [Check the network settings on the data switches](#).

Steps

1. Check the MTU port setting on the storage system:

```
network port show -instance
```

2. Change the MTU port setting to 9000:

```
network port modify -node nodename -port port -mtu 9000
```

Example

The following example changes the MTU port setting for e0a to 9000:

```
cluster1::>*> network port modify -node node0 -port e0a -mtu 9000
```

= Check disk throughput and latency

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can check the disk throughput and latency metrics for cluster nodes to assist you in troubleshooting.

About this task

Advanced privilege level commands are required for this task.

Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Check the disk throughput and latency metrics:

```
statistics disk show -sort-key latency
```

Example

The following example displays the totals in each user read or write operation for node2 on cluster1:

```
::*:> statistics disk show -sort-key latency
cluster1 : 8/24/2015 12:44:15
```

Disk	Node	Busy (%)	Total Ops	Read Ops	Write Ops	Read (Bps)	Write (Bps)	*Latency (us)
1.10.20	node2	4	5	3	2	95232	367616	23806
1.10.8	node2	4	5	3	2	138240	386048	22113
1.10.6	node2	3	4	2	2	48128	371712	19113
1.10.19	node2	4	6	3	2	102400	443392	19106
1.10.11	node2	4	4	2	2	122880	408576	17713

= Check throughput and latency between nodes

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

You can use the `network test-path` command to identify network bottlenecks, or to prequalify network paths between nodes. You can run the command between intercluster nodes or intracluster nodes.

What you'll need

- You must be a cluster administrator to perform this task.
- Advanced privilege level commands are required for this task.
- For an intercluster path, the source and destination clusters must be peered.

About this task

Occasionally, network performance between nodes may not meet expectations for your path configuration. A 1 Gbps transmission rate for the kind of large data transfers seen in SnapMirror replication operations, for example, would not be consistent with a 10 GbE link between the source and destination clusters.

You can use the `network test-path` command to measure throughput and latency between nodes. You can run the command between intercluster nodes or intracluster nodes.

The test saturates the network path with data, so you should run the command when the system is not busy and when network traffic between nodes is not excessive. The test times out after ten seconds. The command can be run only between ONTAP 9 nodes.

The `session-type` option identifies the type of operation you are running over the network path—for example, "AsyncMirrorRemote" for SnapMirror replication to a remote destination. The type dictates the amount of data used in the test. The following table defines the session types:

Session Type	Description
Default	SnapMirror replication between nodes in different clusters
AsyncMirrorLocal	SnapMirror replication between nodes in the same cluster
AsyncMirrorRemote	SnapMirror replication between nodes in different clusters
SyncMirrorRemote	SyncMirror replication between nodes in different clusters
RemoteDataTransfer	Data transfer between nodes in the same cluster (for example, an NFS request to a node for a file stored in a volume on a different node)

Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Measure throughput and latency between nodes:

```
network test-path -source-node source_nodename |local -destination-cluster destination_clustername -destination-node destination_nodename -session -type Default|AsyncMirrorLocal|AsyncMirrorRemote|SyncMirrorRemote|RemoteDataTransfer
```

The source node must be in the local cluster. The destination node can be in the local cluster or in a peered cluster. A value of "local" for `-source-node` specifies the node on which you are running the command.

The following command measures throughput and latency for SnapMirror-type replication operations between `node1` on the local cluster and `node3` on `cluster2`:

```
cluster1::> network test-path -source-node node1 -destination
-cluster cluster2 -destination-node node3 -session-type
AsyncMirrorRemote
Test Duration:      10.88 secs
Send Throughput:   18.23 MB/sec
Receive Throughput: 18.23 MB/sec
MB sent:           198.31
MB received:        198.31
Avg latency in ms: 2301.47
Min latency in ms: 61.14
Max latency in ms: 3056.86
```

3. Return to administrative privilege:

```
set -privilege admin
```

After you finish

If performance does not meet expectations for the path configuration, you should check node performance statistics, use available tools to isolate the problem in the network, check switch settings, and so forth.

= Manage workloads

= Identify remaining performance capacity
:icons: font
:relative_path: ./performance-admin/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/

Performance capacity, or *headroom*, measures how much work you can place on a node or an aggregate before performance of workloads on the resource begins to be affected by latency. Knowing the available performance capacity on the cluster helps you provision and balance workloads.

What you'll need

Advanced privilege level commands are required for this task.

About this task

You can use the following values for the –object option to collect and display headroom statistics:

- For CPUs, `resource_headroom_cpu`.
- For aggregates, `resource_headroom_aggr`.

You can also complete this task using System Manager and Active IQ Unified Manager.

Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Start real-time headroom statistics collection:

```
statistics start -object resource_headroom_cpu|aggr
```

For complete command syntax, see the man page.

3. Display real-time headroom statistics information:

```
statistics show -object resource_headroom_cpu|aggr
```

For complete command syntax, see the man page.

4. Return to administrative privilege:

```
set -privilege admin
```

Example

The following example displays the average hourly headroom statistics for cluster nodes.

You can compute the available performance capacity for a node by subtracting the current_utilization counter from the optimal_point_utilization counter. In this example, the utilization capacity for CPU_sti2520-213 is -14% (72%-86%), which suggests that the CPU has been overutilized on average for the past hour.

You could have specified ewma_daily, ewma_weekly, or ewma_monthly to get the same information averaged over longer periods of time.

```

sti2520-2131454963690::*> statistics show -object resource_headroom_cpu
-raw -counter ewma_hourly
(statistics show)

Object: resource_headroom_cpu
Instance: CPU_sti2520-213
Start-time: 2/9/2016 16:06:27
End-time: 2/9/2016 16:06:27
Scope: sti2520-213

```

= Identify high-traffic clients or files

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest/..media/

You can use ONTAP Active Objects technology to identify clients or files that are responsible for a disproportionately large amount of cluster traffic. Once you have

identified these "top" clients or files, you can rebalance cluster workloads or take other steps to resolve the issue.

What you'll need

You must be a cluster administrator to perform this task.

Steps

1. View the top clients accessing the cluster:

```
statistics top client show -node node_name -sort-key sort_column -interval
seconds_between_updates -iterations iterations -max number_of_instances
```

For complete command syntax, see the man page.

The following command displays the top clients accessing cluster1:

```
cluster1::> statistics top client show

cluster1 : 3/23/2016 17:59:10

*Total
Client Vserver          Node Protocol   Ops
----- -----
172.17.180.170    vs4 sideropl-vsim4   nfs    668
172.17.180.169    vs3 sideropl-vsim3   nfs    337
172.17.180.171    vs3 sideropl-vsim3   nfs    142
172.17.180.170    vs3 sideropl-vsim3   nfs    137
172.17.180.123    vs3 sideropl-vsim3   nfs    137
172.17.180.171    vs4 sideropl-vsim4   nfs     95
172.17.180.169    vs4 sideropl-vsim4   nfs     92
172.17.180.123    vs4 sideropl-vsim4   nfs     92
172.17.180.153    vs3 sideropl-vsim3   nfs      0
```

2. View the top files accessed on the cluster:

```
statistics top file show -node node_name -sort-key sort_column -interval
seconds_between_updates -iterations iterations -max number_of_instances
```

For complete command syntax, see the man page.

The following command displays the top files accessed on cluster1:

```
cluster1::> statistics top file show
```

```
cluster1 : 3/23/2016 17:59:10
```

*Total

= Guarantee throughput with QoS

= Guarantee throughput with QoS overview

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You can use storage quality of service (QoS) to guarantee that performance of critical workloads is not degraded by competing workloads. You can set a throughput *ceiling* on a competing workload to limit its impact on system resources, or set a throughput *floor* for a critical workload, ensuring that it meets minimum throughput targets, regardless of demand by competing workloads. You can even set a ceiling and floor for the same workload.

== About throughput ceilings (QoS Max)

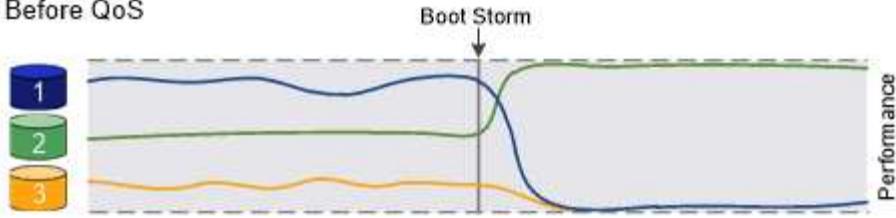

A throughput ceiling limits throughput for a workload to a maximum number of IOPS or MBps, or IOPS and MBps. In the figure below, the throughput ceiling for workload 2 ensures that it does not "bully" workloads 1 and 3.

A *policy group* defines the throughput ceiling for one or more workloads. A workload represents the I/O operations for a *storage object*: a volume, file, qtree or LUN, or all the volumes, files, qtrees, or LUNs in an SVM. You can specify the ceiling when you create the policy group, or you can wait until after you monitor workloads to specify it.

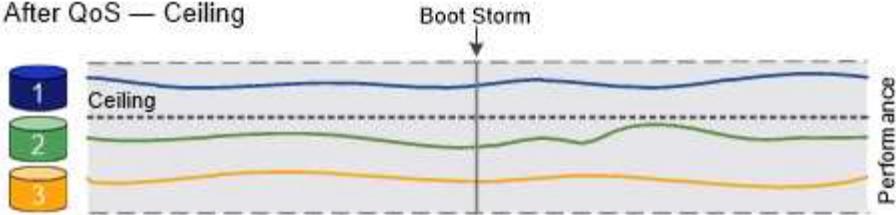

Throughput to workloads might exceed the specified ceiling by up to 10%, especially if a workload experiences rapid changes in throughput. The ceiling might be exceeded by up to 50% to handle bursts. Bursts occur on single nodes when tokens accumulate up to 150%

Before QoS

After QoS — Ceiling

== About throughput floors (QoS Min)

A throughput floor guarantees that throughput for a workload does not fall below a minimum number of IOPS or MBps, or IOPS and MBps. In the figure below, the throughput floors for workload 1 and workload 3 ensure that they meet minimum throughput targets, regardless of demand by workload 2.

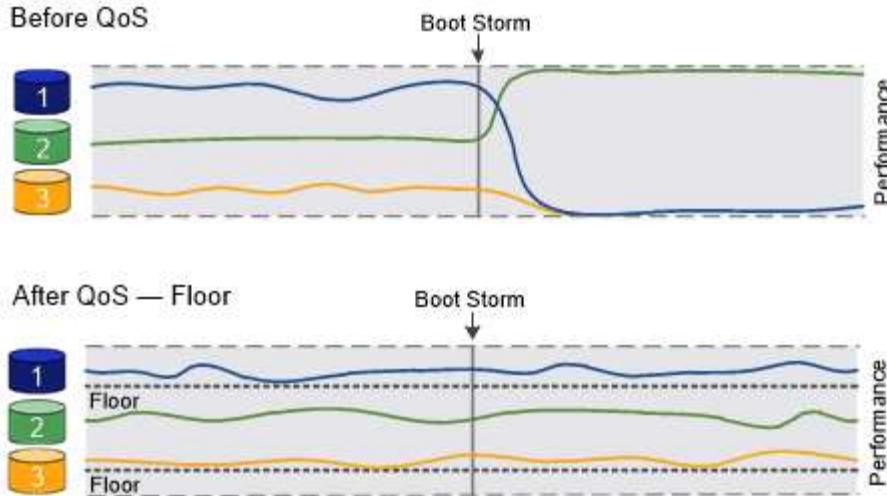

As the examples suggest, a throughput ceiling throttles throughput directly. A throughput floor throttles throughput indirectly, by giving priority to the workloads for which the floor has been set.

A policy group that defines a throughput floor cannot be applied to an SVM. You can specify the floor when you create the policy group, or you can wait until after you monitor workloads to specify it.

In releases before ONTAP 9.7, throughput floors are guaranteed when there is sufficient performance capacity available. In ONTAP 9.7 and later, throughput floors can be guaranteed even when there is insufficient performance capacity available. This new floor behavior is called floors v2. To meet the guarantees, floors v2 can result in higher latency on workloads without a throughput floor or on work that exceeds the floor settings. Floors v2 applies to both QoS and adaptive QoS. The option of enabling/disabling the new behavior of floors v2 is available in ONTAP 9.7P6 and later. A workload might fall below the specified floor during critical operations like volume move trigger-cutover. Even when sufficient capacity is available and critical operations are not taking place, throughput to a workload might fall below the specified floor by up to 5%. If floors are overprovisioned and there is no performance capacity, some workloads might fall below the specified floor.

== About shared and non-shared QoS policy groups

Beginning with ONTAP 9.4, you can use a *non-shared* QoS policy group to specify that the defined throughput ceiling or floor applies to each member workload individually. Behavior of *shared* policy groups depends on the policy type:

- For throughput ceilings, the total throughput for the workloads assigned to the shared policy group cannot exceed the specified ceiling.
- For throughput floors, the shared policy group can be applied to a single workload only.

== About adaptive QoS

Ordinarily, the value of the policy group you assign to a storage object is fixed. You need to change the value manually when the size of the storage object changes. An increase in the amount of space used on a volume, for example, usually requires a corresponding increase in the throughput ceiling specified for the volume.

Adaptive QoS automatically scales the policy group value to workload size, maintaining the ratio of IOPS to TBs|GBs as the size of the workload changes. That is a significant advantage when you are managing hundreds or thousands of workloads in a large deployment.

You typically use adaptive QoS to adjust throughput ceilings, but you can also use it to manage throughput floors (when workload size increases). Workload size is expressed as either the allocated space for the storage object or the space used by the storage object.

Used space is available for throughput floors in ONTAP 9.5 and later. It is not supported for throughput floors in ONTAP 9.4 and earlier.

- An *allocated space* policy maintains the IOPS/TB|GB ratio according to the nominal size of the storage object. If the ratio is 100 IOPS/GB, a 150 GB volume will have a throughput ceiling of 15,000 IOPS for as long as the volume remains that size. If the volume is resized to 300 GB, adaptive QoS adjusts the throughput ceiling to 30,000 IOPS.
- A *used space* policy (the default) maintains the IOPS/TB|GB ratio according to the amount of actual data stored before storage efficiencies. If the ratio is 100 IOPS/GB, a 150 GB volume that has 100 GB of data stored would have a throughput ceiling of 10,000 IOPS. As the amount of used space changes, adaptive QoS adjusts the throughput ceiling according to the ratio.

Beginning with ONTAP 9.5, you can specify an I/O block size for your application that enables a

throughput limit to be expressed in both IOPS and MBps. The MBps limit is calculated from the block size multiplied by the IOPS limit. For example, an I/O block size of 32K for an IOPS limit of 6144IOPS/TB yields an MBps limit of 192MBps.

You can expect the following behavior for both throughput ceilings and floors:

- When a workload is assigned to an adaptive QoS policy group, the ceiling or floor is updated immediately.
- When a workload in an adaptive QoS policy group is resized, the ceiling or floor is updated in approximately five minutes.

Throughput must increase by at least 10 IOPS before updates take place.

Adaptive QoS policy groups are always non-shared: the defined throughput ceiling or floor applies to each member workload individually.

Beginning with ONTAP 9.6, throughput floors is supported on ONTAP Select premium with SSD.

== General support

The following table shows the differences in support for throughput ceilings, throughput floors, and adaptive QoS.

Resource or feature	Throughput ceiling	Throughput floor	Throughput floor v2	Adaptive QoS
ONTAP 9 version	All	9.2 and later	9.7 and later	9.3 and later
Platforms	All	<ul style="list-style-type: none">• AFF• C190 *• ONTAP Select premium with SSD *	<ul style="list-style-type: none">• AFF• C190• ONTAP Select premium with SSD	All
Protocols	All	All	All	All
FabricPool	Yes	Yes, if the tiering policy is set to "none" and no blocks are in the cloud.	Yes, if the tiering policy is set to "none" and no blocks are in the cloud.	Yes
SnapMirror Synchronous	Yes	No	No	Yes

*C190 and ONTAP Select support started with the ONTAP 9.6 release.

== Supported workloads for throughput ceilings

The following table shows workload support for throughput ceilings by ONTAP 9 version. Root volumes, load-sharing mirrors, and data protection mirrors are not supported.

Workload support - ceiling	9.0	9.1	9.2	9.3	9.4 and later	9.8 and later
Volume	yes	yes	yes	yes	yes	yes
File	yes	yes	yes	yes	yes	yes
LUN	yes	yes	yes	yes	yes	yes
SVM	yes	yes	yes	yes	yes	yes
FlexGroup volume	no	no	no	yes	yes	yes
qtrees*	no	no	no	no	no	yes
Multiple workloads per policy group	yes	yes	yes	yes	yes	yes
Non-shared policy groups	no	no	no	no	yes	yes

*Beginning with ONTAP 9.8, NFS access is supported in qtrees in FlexVol and FlexGroup volumes with NFS enabled. Beginning with ONTAP 9.9.1, SMB access is also supported in qtrees in FlexVol and FlexGroup volumes with SMB enabled.

== Supported workloads for throughput floors

The following table shows workload support for throughput floors by ONTAP 9 version. Root volumes, load-sharing mirrors, and data protection mirrors are not supported.

Workload support - floor	9.2	9.3	9.4 and later	9.8 and later
Volume	yes	yes	yes	yes
File	no	yes	yes	yes
LUN	yes	yes	yes	yes
SVM	no	no	no	yes
FlexGroup volume	no	no	yes	yes
qtrees *	no	no	no	yes

Multiple workloads per policy group	no	no	yes	yes
Non-shared policy groups	no	no	yes	yes

*Beginning with ONTAP 9.8, NFS access is supported in qtrees in FlexVol and FlexGroup volumes with NFS enabled. Beginning with ONTAP 9.9.1, SMB access is also supported in qtrees in FlexVol and FlexGroup volumes with SMB enabled.

== Supported workloads for adaptive QoS

The following table shows workload support for adaptive QoS by ONTAP 9 version. Root volumes, load-sharing mirrors, and data protection mirrors are not supported.

Workload support - adaptive QoS	9.3	9.4 and later
Volume	yes	yes
File	no	yes
LUN	no	yes
SVM	no	no
FlexGroup volume	no	yes
Multiple workloads per policy group	yes	yes
Non-shared policy groups	yes	yes

== Maximum number of workloads and policy groups

The following table shows the maximum number of workloads and policy groups by ONTAP 9 version.

Workload support	9.3 and earlier	9.4 and later
Maximum workloads per cluster	12,000	40,000
Maximum workloads per node	12,000	40,000
Maximum policy groups	12,000	12,000

= Enable or disable throughput floors v2

:icons: font

:relative_path: ./performance-admin/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/
```

You can enable or disable throughput floors v2 on AFF. The default is enabled. With floors v2 enabled, throughput floors can be met when controllers are heavily used at the expense of higher latency on other workloads. Floors v2 applies to both QoS and Adaptive QoS.

Steps

1. Change to advanced privilege level:

```
set -privilege advanced
```

2. Enter one of the following commands:

If you want to...	Use this command:
Disable floors v2	qos settings throughput-floors-v2 -enable false
Enable floors v2	qos settings throughput-floors-v2 -enable true

To disable throughput floors v2 in an MetroCluster cluster, you must run the

qos settings throughput-floors-v2 -enable false
command on both the source and destination clusters.

```
cluster1::*> qos settings throughput-floors-v2 -enable false
```

= Storage QoS workflow

:icons: font

:relative_path: ./performance-admin/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/
```

If you already know the performance requirements for the workloads you want to manage with QoS, you can specify the throughput limit when you create the policy group. Otherwise, you can wait until after you monitor the workloads to specify the limit.

= Set a throughput ceiling with QoS

:icons: font

:relative_path: ./performance-admin/

```
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/../media/
```

You can use the `max-throughput` field for a policy group to define a throughput ceiling for storage object workloads (QoS Max). You can apply the policy group when

you create or modify the storage object.

What you'll need

- You must be a cluster administrator to create a policy group.
- You must be a cluster administrator to apply a policy group to an SVM.

About this task

- Beginning with ONTAP 9.4, you can use a *non-shared* QoS policy group to specify that the defined throughput ceiling applies to each member workload individually. Otherwise, the policy group is *shared*: the total throughput for the workloads assigned to the policy group cannot exceed the specified ceiling.

Set `-is-shared=false` for the `qos policy-group create` command to specify a non-shared policygroup.

- You can specify the throughput limit for the ceiling in IOPS, MB/s, or IOPS, MB/s. If you specify both IOPS and MB/s, whichever limit is reached first is enforced.

If you set a ceiling and a floor for the same workload, you can specify the throughput limit for the ceiling in IOPS only.

- A storage object that is subject to a QoS limit must be contained by the SVM to which the policy group belongs. Multiple policy groups can belong to the same SVM.
- You cannot assign a storage object to a policy group if its containing object or its child objects belong to the policy group.
- It is a QoS best practice to apply a policy group to the same type of storage objects.

Steps

1. Create a policy group:

```
qos policy-group create -policy-group policy_group -vserver SVM -max-throughput number_of_iops|Mb/S|iops,Mb/S -is-shared true|false
```

For complete command syntax, see the man page. You can use the `qos policy-group modify` command to adjust throughput ceilings.

The following command creates the shared policy group `pg-vs1` with a maximum throughput of 5,000 IOPS:

```
cluster1::> qos policy-group create -policy-group pg-vs1 -vserver vs1 -max-throughput 5000iops -is-shared true
```

The following command creates the non-shared policy group `pg-vs3` with a maximum throughput of 100 IOPS and 400 Kb/S:

```
cluster1::> qos policy-group create -policy-group pg-vs3 -vserver vs3 -max-throughput 100iops,400KB/s -is-shared false
```

The following command creates the non-shared policy group pg-vs4 without a throughput limit:

```
cluster1::> qos policy-group create -policy-group pg-vs4 -vserver vs4 -is-shared false
```

2. Apply a policy group to an SVM, file, volume, or LUN:

```
storage_object create -vserver SVM -qos-policy-group policy_group
```

For complete command syntax, see the man pages. You can use the `storage_object modify` command to apply a different policy group to the storage object.

The following command applies policy group pg-vs1 to SVM vs1:

```
cluster1::> vserver create -vserver vs1 -qos-policy-group pg-vs1
```

The following commands apply policy group pg-app to the volumes app1 and app2:

```
cluster1::> volume create -vserver vs2 -volume app1 -aggregate aggr1 -qos-policy-group pg-app
```

```
cluster1::> volume create -vserver vs2 -volume app2 -aggregate aggr1 -qos-policy-group pg-app
```

3. Monitor policy group performance:

```
qos statistics performance show
```

For complete command syntax, see the man page.

Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

The following command shows policy group performance:

```
cluster1::> qos statistics performance show
```

Policy Group	IOPS	Throughput	Latency
-total-	12316	47.76MB/s	1264.00us
pg_vs1	5008	19.56MB/s	2.45ms
_System-Best-Effort	62	13.36KB/s	4.13ms
_System-Background	30	0KB/s	0ms

4. Monitor workload performance:

```
qos statistics workload performance show
```

For complete command syntax, see the man page.

Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

The following command shows workload performance:

```
cluster1::> qos statistics workload performance show
Workload          ID      IOPS      Throughput      Latency
-----  -----
-total-           -    12320    47.84MB/s   1215.00us
app1-wid7967     7967    7219    28.20MB/s   319.00us
vs1-wid12279     12279    5026    19.63MB/s   2.52ms
_USERSPACE_APPS   14      55      10.92KB/s  236.00us
_Scan_Backgro...  5688     20      0KB/s       0ms
```

You can use the `qos statistics workload latency show` command to view detailed latency statistics for QoS workloads.

= Set a throughput floor with QoS

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

You can use the `min-throughput` field for a policy group to define a throughput floor for storage object workloads (QoS Min). You can apply the policy group when you create or modify the storage object. Beginning with ONTAP 9.8, you can specify the throughput floor in IOPS or MBps, or IOPS and MBps.

What you'll need

- You must be running ONTAP 9.2 or later. Throughput floors are available beginning with ONTAP 9.2.
- You must be a cluster administrator to create a policy group.

About this task

- Beginning with ONTAP 9.4, you can use a *non-shared* QoS policy group to specify that the defined throughput floor be applied to each member workload individually. This is the only condition in which a policy group for a throughput floor can be applied to multiple workloads.

Set `-is-shared=false` for the `qos policy-group create` command to specify a non-shared policy group.

- Throughput to a workload might fall below the specified floor if there is insufficient performance capacity (headroom) on the node or aggregate.

- A storage object that is subject to a QoS limit must be contained by the SVM to which the policy group belongs. Multiple policy groups can belong to the same SVM.
- It is a QoS best practice to apply a policy group to the same type of storage objects.
- A policy group that defines a throughput floor cannot be applied to an SVM.

Steps

1. Check for adequate performance capacity on the node or aggregate, as described in [permalink :identify-remaining-performance-capacity-task.html](#)[Identifying remaining performance capacity].
2. Create a policy group:

```
qos policy-group create -policy group policy_group -vserver SVM -min-throughput qos_target -is-shared true|false
```

For complete command syntax, see the man page for your ONTAP release. You can use the `qos policy-group modify` command to adjust throughput floors.

The following command creates the shared policy group `pg-vs2` with a minimum throughput of 1,000 IOPS:

```
cluster1::> qos policy-group create -policy group pg-vs2 -vserver vs2 -min-throughput 1000iops -is-shared true
```

The following command creates the non-shared policy group `pg-vs4` without a throughput limit:

```
cluster1::> qos policy-group create -policy group pg-vs4 -vserver vs4 -is-shared false
```

3. Apply a policy group to a volume or LUN:

```
storage_object create -vserver SVM -qos-policy-group policy_group
```

For complete command syntax, see the man pages. You can use the `_storage_object_modify` command to apply a different policy group to the storage object.

The following command applies policy group `pg-app2` to the volume `app2`:

```
cluster1::> volume create -vserver vs2 -volume app2 -aggregate aggr1 -qos-policy-group pg-app2
```

4. Monitor policy group performance:

```
qos statistics performance show
```

For complete command syntax, see the man page.

Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

The following command shows policy group performance:

```
cluster1::> qos statistics performance show
Policy Group          IOPS      Throughput     Latency
-----
-total-                12316    47.76MB/s   1264.00us
pg_app2                  7216    28.19MB/s   420.00us
_System-Best-Effort       62     13.36KB/s   4.13ms
_System-Background        30      0KB/s      0ms
```

5. Monitor workload performance:

```
qos statistics workload performance show
```

For complete command syntax, see the man page.

Monitor performance from the cluster. Do not use a tool on the host to monitor performance.

The following command shows workload performance:

```
cluster1::> qos statistics workload performance show
Workload      ID      IOPS      Throughput     Latency
-----
-total-        -      12320    47.84MB/s   1215.00us
app2-wid7967   7967    7219    28.20MB/s   319.00us
vs1-wid12279   12279   5026    19.63MB/s   2.52ms
_USERSPACE_APPS   14      55     10.92KB/s   236.00us
_Scan_Backgro..  5688     20      0KB/s      0ms
```

You can use the `qos statistics workload latency show` command to view detailed latency statistics for QoS workloads.

= Use adaptive QoS policy groups

:icons: font

:relative_path: ./performance-admin/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/./media/

You can use an *adaptive QoS* policy group to automatically scale a throughput ceiling or floor to volume size, maintaining the ratio of IOPS to TBs|GBs as the size of the volume changes. That is a significant advantage when you are managing hundreds or thousands of workloads in a large deployment.

What you'll need

- You must be running ONTAP 9.3. Adaptive QoS policy groups are available beginning with ONTAP 9.3.
- You must be a cluster administrator to create a policy group.

About this task

A storage object can be a member of an adaptive policy group or a non-adaptive policy group, but not both. The SVM of the storage object and the policy must be the same. The storage object must be online.

Adaptive QoS policy groups are always non-shared: the defined throughput ceiling or floor applies to each member workload individually.

The ratio of throughput limits to storage object size is determined by the interaction of the following fields:

- `expected-iops` is the minimum expected IOPS per allocated TB|GB.

`expected-iops` is guaranteed on AFF platforms only. `expected-iops` is guaranteed for FabricPool only if the tiering policy is set to "none" and no blocks are in the cloud. `expected-iops` is guaranteed for volumes that are not in a SnapMirror Synchronous relationship.

- `peak-iops` is the maximum possible IOPS per allocated or used TB|GB.

- `expected-iops-allocation` specifies whether allocated space (the default) or used space is used for `expected-iops`.

`expected-iops-allocation` is available in ONTAP 9.5 and later. It is not supported in ONTAP 9.4 and earlier.

- `peak-iops-allocation` specifies whether allocated space or used space (the default) is used for `peak-iops`.

- `absolute-min-iops` is the absolute minimum number of IOPS. You can use this field with very small storage objects. It overrides both `peak-iops` and/or `expected-iops` when `absolute-min-iops` is greater than the calculated `expected-iops`.

For example, if you set `expected-iops` to 1,000 IOPS/TB, and the volume size is less than 1 GB, the calculated `expected-iops` will be a fractional IOP. The calculated `peak-iops` will be an even smaller fraction. You can avoid this by setting `absolute-min-iops` to a realistic value.

- `block-size` specifies the application I/O block size. The default is 32K. Valid values are 8K, 16K, 32K, 64K, ANY. ANY means that the block size is not enforced.

Three default adaptive QoS policy groups are available, as shown in the following table. You can apply these policy groups directly to a volume.

Default policy group	Expected IOPS/TB	Peak IOPS/TB	Absolute Min IOPS
extreme	6,144	12,288	1000
performance	2,048	4,096	500

value	128	512	75
-------	-----	-----	----

Steps

1. Create an adaptive QoS policy group:

```
qos adaptive-policy-group create -policy group policy_group -vserver SVM
-expected-iops number_of_iops/TB|GB -peak-iops number_of_iops/TB|GB
-expected-iops-allocation-space|used-space -peak-iops-allocation allocated-
space|used-space -absolute-min-iops number_of_iops -block-size
8K|16K|32K|64K|ANY
```

For complete command syntax, see the man page.

-expected-iops-allocation and -block-size is available in ONTAP 9.5 and later. These options are not supported in ONTAP 9.4 and earlier.

The following command creates adaptive QoS policy group adpg-app1 with -expected-iops set to 300 IOPS/TB, -peak-iops set to 1,000 IOPS/TB, -peak-iops-allocation set to used-space, and -absolute-min-iops set to 50 IOPS:

```
cluster1::> qos adaptive-policy-group create -policy group adpg-app1
-vserver vs2 -expected-iops 300iops/tb -peak-iops 1000iops/TB -peak-
-iops-allocation used-space -absolute-min-iops 50iops
```

2. Apply an adaptive QoS policy group to a volume:

```
volume create -vserver SVM -volume volume -aggregate aggregate -size
number_of TB|GB -qos-adaptive-policy-group policy_group
```

For complete command syntax, see the man pages.

The following command applies adaptive QoS policy group adpg-app1 to volume app1:

```
cluster1::> volume create -vserver vs1 -volume app1 -aggregate aggr1
-size 2TB -qos-adaptive-policy-group adpg-app1
```

The following commands apply the default adaptive QoS policy group `extreme` to the new volume app4 and to the existing volume app5. The throughput ceiling defined for the policy group applies to volumes app4 and app5 individually:

```
cluster1::> volume create -vserver vs4 -volume app4 -aggregate aggr4
-size 2TB -qos-adaptive-policy-group extreme
```

```
cluster1::> volume modify -vserver vs5 -volume app5 -qos-adaptive  
-policy-group extreme
```

= Monitor cluster performance with Unified Manager

:toc: macro

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

With Active IQ Unified Manager, you can maximize availability and maintain control of your NetApp AFF and FAS storage infrastructure for improved scalability, supportability, performance, and security.

Active IQ Unified Manager continuously monitors system health and send alerts, so your organization can free up IT staff resources. You can instantly view storage status from a single dashboard and quickly address issues through recommended actions.

Data management is simplified because you can discover, monitor, and receive notifications to proactively manage storage and quickly resolve issues. Admin efficiency is improved because you can monitor petabytes of data from a single dashboard and manage your data at scale.

With Active IQ Unified Manager, you can keep pace with fluctuating business demands, optimizing performance using performance data and advanced analytics. The reporting capabilities allow you to access standard reports or create custom operational reports to meet the specific needs of your business.

= Monitor cluster performance with Cloud Insights

:toc: macro

:linkatrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

NetApp Cloud Insights is a monitoring tool that gives you visibility into your complete infrastructure. With Cloud Insights, you can monitor, troubleshoot, and optimize all your resources including your public clouds and your private data centers.

-- Cloud Insights comes in two editions

Cloud Insights Basic Edition is designed specifically to monitor and optimize your NetApp Data Fabric assets. It provides advanced analytics for the connections between all NetApp resources including HCI and All Flash FAS (AFF) within the environment free of charge.

Cloud Insights Standard Edition focuses not only on NetApp Data Fabric-enabled infrastructure components, but also on multi-vendor and multi-cloud environments. With its enriched capabilities, you can access support for over 100 services and resources.

In today's world, with resources in play from your on-premises data centers to multiple public clouds, it's crucial to have the complete picture from the application itself to the backend disk of the storage array. The additional support for application monitoring (like Kafka, MongoDB, and Nginx) gives you the information and knowledge you need to operate at the optimal level of utilization as well as with the perfect risk buffer.

Both editions (Basic and Standard) can integrate with NetApp Active IQ Unified Manager. Customers who use Active IQ Unified Manager will be able to see join information inside the Cloud Insights user interface. Notifications posted on Active IQ Unified Manager will not be overlooked and can now be correlated to events in Cloud Insights. In other words, you get the best of both worlds.

== Monitor, troubleshoot, and optimize all your resources

Cloud Insights helps you significantly reduce the time to resolve issues and prevent them from impacting end users. It also helps you reduce cloud infrastructure costs. Your exposure to insider threats is reduced by protecting your data with actionable intelligence.

Cloud Insights gives you visibility to your entire hybrid infrastructure in one place—from the public cloud to your data center. You can instantly create relevant dashboards that can be customized to your specific needs. You can also create targeted and conditional alerts that are specific and relevant to your organization's needs.

Advanced anomaly detection helps you proactively fix issues before they arise. You can view resource contention and degradation automatically to quickly restore impacted workloads. Troubleshooting goes more quickly with the automatically built hierarchy of relationships between the different components in your stack.

You can identify unused or abandoned resources across your environment, which helps you discover opportunities to right-size the infrastructure and optimize your entire spend.

Cloud Insights visualizes your system topology to gain an understanding of your Kubernetes architecture. You can monitor the health of your Kubernetes clusters, including which nodes are in trouble, and zoom in when you see a problem.

Cloud Insights helps you protect organizational data from being misused by malicious or compromised users through advanced machine learning and anomaly detection that gives you actionable intelligence on insider threats.

Cloud Insights helps you to visualize Kubernetes metrics so you can fully understand the relations between your pods, nodes, and clusters. You're able to assess the health of a cluster or a working pod, as well as the load it is currently processing—enabling you to take command of your K8S cluster and to control both the health and the cost of your deployment.

= File System Analytics

= File System Analytics overview

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

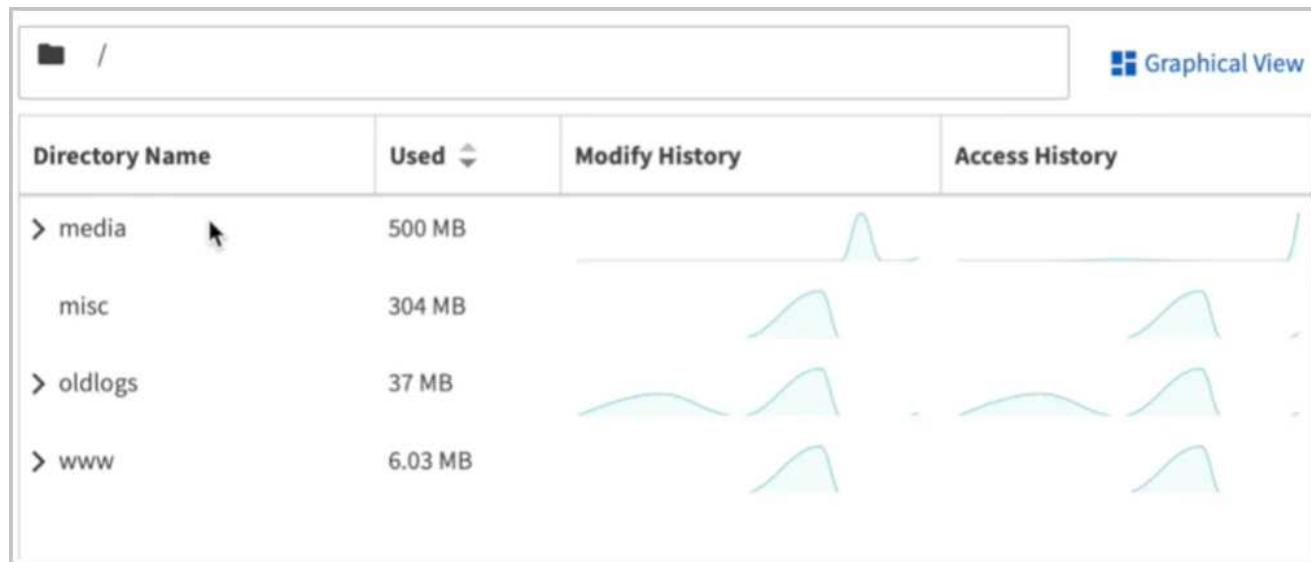

Beginning with ONTAP 9.8, File System Analytics (FSA) is a framework for collecting

and visualizing key data points about the contents of ONTAP FlexGroup or FlexVol volumes. FSA helps solve organizational data challenges around data locality, storage consumption, storage optimization, and data protection. By providing real-time insights into data usage, FSA helps you with decision-making in effective data management and operations, such as quality-of-service changes to throughput and moving volumes to a different controller or aggregate.

FSA presents detailed information at each level of the volume's file system hierarchy, allowing you to:

- Assess capacity usage and trends
- Monitor file and directory counts
- Evaluate file activity and history
- Capture information on inactive data
- Take corrective action based on insights (beginning with ONTAP 9.9.1)
- Analyze and download information on high traffic and high throughput activity (beginning with ONTAP 9.10.1)

File System Analytics offers a list and graphical view of your data. In the graphical view, variably sized blocks and color shades provide a graphical representation of the directories. In the list view shown below, you can see how much space each directory uses as well modification and access histories in numerical form and in interactive graphs for each directory.

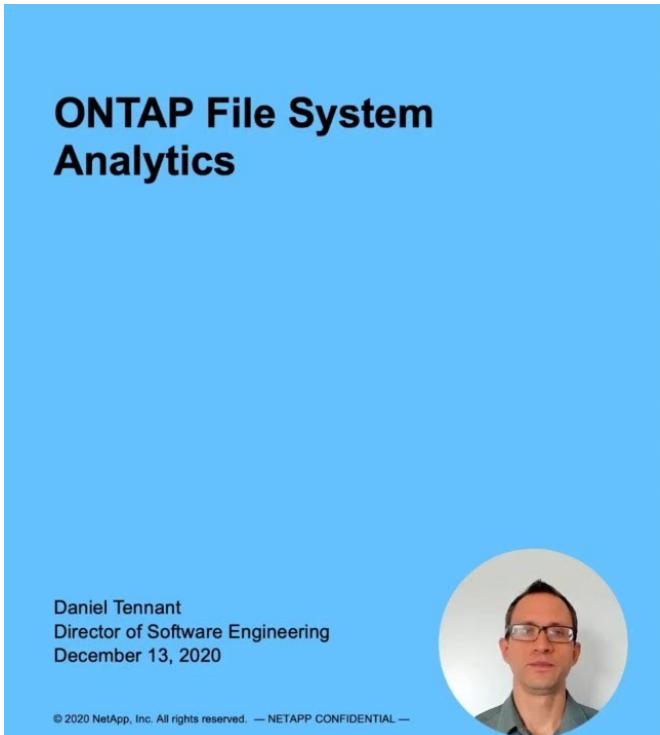

File System Analytics data is displayed using ONTAP System Manager. You can also use the ONTAP REST API to access the data programmatically.

Feature availability by release

	ONTAP 9.8	ONTAP 9.9.1	ONTAP 9.10.1
Visualization in System Manager	X	X	X
Capacity analytics	X	X	X
Inactive Data information	X	X	X

Availability for volumes transitioned from 7-mode systems		X	X
Option to change Inactive period in System Manager		X	X
Activity Tracking			X
Download to CSV (Activity Tracking)			X

== Learn more about File System Analytics

The slide has a blue header section containing the title "ONTAP File System Analytics". Below the title is a circular profile picture of Daniel Tenant, Director of Software Engineering, and the date December 13, 2020. The footer contains the copyright notice "© 2020 NetApp, Inc. All rights reserved. — NETAPP CONFIDENTIAL —".

The slide features a large blue rectangular area on the right side containing a 3D illustration of several stacked cylinders, representing data storage.

[TR 4687: Best-practice guidelines for ONTAP File System Analytics](#)

= Enable File System Analytics

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../encryption-at-rest./media/

To collect and display usage data such as capacity analytics, you must enable File System Analytics.

You can enable File System Analytics when you create a new volume or when you upgrade a system with volumes to ONTAP 9.8 or later. After upgrading, ensure that all upgrade processes have completed before enabling analytics.

== Procedure

Depending on the size and contents of the volume, enabling analytics may take time while ONTAP processes existing data in the volume. System Manager displays progress and presents analytics data when complete. If you need more precise information about initialization progress, you can use the ONTAP CLI command `volume analytics show`.

You can enable File System Analytics with ONTAP System Manager, the ONTAP CLI, or the ONTAP REST API.

System Manager

In ONTAP 9.8 and 9.9.1	Beginning in ONTAP 9.10.1
<ol style="list-style-type: none">1. Select Storage > Volumes.2. Select the desired volume, then select Explorer.3. Select Enable Analytics or Disable Analytics.	<ol style="list-style-type: none">1. Select Storage > Volumes.2. Select the desired volume. From the individual volume menu, select File System > Explorer.3. Select Enable Analytics or Disable Analytics.

CLI

To enable File System Analytics with the CLI:

1. Run the following command:

```
volume analytics on -vserver svm_name -volume volume_name [-foreground {true|false}]
```

By default, the command runs in the foreground; ONTAP displays progress and presents analytics data when complete. If you need more precise information, you can run the command in the background by using the `-foreground false` option and then use the `volume analytics show` command to display initialization progress in the CLI.

2. After successfully enabling File System Analytics, use ONTAP System Manager or the ONTAP REST API to display the analytic data.

= View file system activity

:toc: macro

:toclevels: 1

:hardbreaks:

:icons: font

:linkatrrs:

:relative_path: ./

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/

After File System Analytics (FSA) is enabled, by default you can view the root directory contents of a selected volume sorted by the spaced used in each subtree.

Clicking on any file system object allows you to browse the file system and to display detailed information about each object in a directory. Information about directories can also be displayed graphically. Over time, historical data is displayed for each subtree. Space used is not sorted if there are more than 3000 directories.

== Explorer

The File System Analytics **Explorer** screen consists of three areas:

- Tree view of directories and subdirectories; expandable list showing name, size, modify history, and access history.
- Files; showing name, size, and accessed time for the object selected in the directory list.
- Active and inactive data comparison for the object selected in the directory list.

Beginning with ONTAP 9.9.1, you can customize the range to be reported. The default value is one year. Based on these customizations, you can take corrective actions, such as moving volumes and modifying the tiering policy.

Accessed time is shown by default. However, if the volume default has been altered from the CLI, by setting the `-atime-update` option to `false` with the `volume modify` command, only last modified time is shown. For example:

- The tree view will not display the **access history**.
- The files view will be altered.
- The active/inactive data view will be based on modified time (`mtime`).

Using these displays, you can examine the following:

- File system locations consuming the most space
- Detailed information about a directory tree, including file and subdirectory count within directories and subdirectories
- File system locations that contain old data (for example, scratch, temp, or log trees)

Keep the following points in mind when interpreting FSA output:

- FSA show where and when your data is in use, not how much data is being processed. For example, large space consumption by recently accessed or modified files does not necessarily indicate high system processing loads.
- The way that the **Volume Explorer** tab calculates space consumption for FSA might differ from other tools. In particular, there could be significant differences compared to the consumption reported in the **Volume Overview** if the volume has storage efficiency features enabled. This is because the **Volume Explorer** tab does not include efficiency savings.
- Due to space limitations in the directory display, it is not possible to view a directory depth greater than 8 levels in the *List View*. To view directories more than 8 levels deep, you must switch to *Graphical View*, locate the desired directory, then switch back to *List View*. This will allow additional screen space in the display.

Procedure

In ONTAP 9.8 and 9.9.1	Beginning in ONTAP 9.10.1
Click Storage > Volumes , select the desired volume, then click Explorer .	Select Storage > Volumes , select the desired volume. From the individual volume menu, select File System > Explorer .

= Enable Activity Tracking

:icons: font

:relative_path: ./file-system-analytics/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

Beginning with ONTAP 9.10.1, File System Analytics includes an Activity Tracking feature that allows you to identify hot objects with Activity Tracking and download them as CSV file.

Activity Tracking enables monitoring in four categories:

- Directories
- Files
- Clients
- Users

For each category monitored, Activity Tracking will display read IOPs, write IOPs, read throughputs, and write throughputs. Queries on Activity Tracking refresh every 10 to 15 seconds pertaining to hot spots seen in the system over the previous five-second interval.

Activity tracking information is approximate, and the accuracy of the data depends on the distribution of the incoming I/O traffic.

When viewing Activity Tracking in System Manager, only the menu of the expanded volume will actively refresh. If the view of any volumes are collapsed, they will not refresh until the volume display is expanded. You can stop the refreshes with the **Pause Refresh** button. Activity data can be downloaded in a CSV format that will display all the point-in-time data captured for the selected volume.

== Procedures

You can enable Activity Tracking with ONTAP System Manager, the ONTAP CLI, or the ONTAP REST API.

System Manager

1. Select **Storage > Volumes**. Select the desired volume. From the individual volume menu, select File System and then select the Activity tab.
2. Ensure **Activity Tracking** is turned on to view individual reports on top directories, files, clients, and users.
3. To analyze data in greater depth without refreshes, select **Pause Refresh**. You can download the data to have a CSV record of the report as well.

CLI

1. Enable Activity Tracking:
`volume activity-tracking on -vsserver svm_name -volume volume_name`
2. You can check if the Activity Tracking state for a volume is on or off with the command:
`volume activity-tracking show -vsserver svm_name -volume volume_name -state`
3. Once enabled, use ONTAP System Manager or the ONTAP REST API to display Activity Tracking data.

= Take corrective action based on analytics

:toc: macro
:toclevels: 1

```
:hardbreaks:  
:icons: font  
:linkatrrs:  
:relative_path: ./  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest./media/
```

Beginning with ONTAP 9.9.1, you can take corrective actions directly from File System Analytics displays based on current data and desired outcomes.

When analytics are enabled, you can take the following actions:

- Delete directories and files

In the Explorer display, you can select directories or individual files to delete. Directories are deleted with low-latency fast directory delete functionality. (Fast directory delete is also available beginning in ONTAP 9.9.1 without analytics enabled.)

- Assign media cost in storage tiers to compare costs of inactive data storage locations

Media cost is a value that you assign based on your evaluation of storage costs, represented as your choice of currency per GB. When set, System Manager uses the assigned media cost to project estimated savings when you move volumes.

The media cost you set is not persistent; it can only be set for a single browser session.

- Move volumes to reduce storage costs

Based on analytics displays and media cost comparisons, you can move volumes to less expensive storage in local tiers.

Only one volume at a time can be compared and moved.

Steps

To perform this action...	Take these steps...
Delete directories or files	<p>1. Click Storage > Volumes, then click Explorer.</p> <p>When you hover over a file or folder, the option to delete appears. You can only delete one object at a time.</p> <p> When directories and files are deleted, the new storage capacity values are not displayed immediately.</p>

To perform this action...	Take these steps...
Enable media cost comparison	<ol style="list-style-type: none"> Click Storage > Tiers, then click Set Media Cost in the desired local tier (aggregate) tiles. Be sure to select active and inactive tiers to enable comparison. Enter a currency type and amount. When you enter or change the media cost, the change is made in all media types.
Move volumes to a less expensive tier	<ol style="list-style-type: none"> After enabling media cost display, click Storage > Tiers, then click Volumes. To compare destination options for a volume, click  for the volume, then click Move. In the Select Destination Local Tier display, select destination tiers to display the estimated cost difference. After comparing options, select the desired tier and click Move.

= Considerations for File System Analytics

:icons: font

:relative_path: ./file-system-analytics/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest/..media/

You should be aware of certain usage limits and potential performance impacts associated with implementing File System Analytics.

-- Supported volume types

File System Analytics is designed to provide visibility on volumes with active NAS data, with the exception of FlexCache caches and SnapMirror destination volumes.

-- Performance considerations

Enabling File System Analytics may incur a performance impact during the initial metadata collection. Do not enable analytics on the systems that are at a maximum utilization.

ONTAP System Manager provides [performance monitoring tools](#) to manage cluster health and metrics.

SVM protected relationships

If you have enabled File System Analytics on volumes whose containing SVM is in a protection relationship, the analytics data is not replicated to the destination SVM. If the source SVM must be resynchronized in a recovery operation, you must manually reenable analytics on desired volumes after recovery.

= EMS configuration

= EMS configuration overview
:icons: font
:relative_path: ./error-messages/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.encryption-at-rest../media/

You can quickly configure ONTAP 9 to send important EMS (Event Management System) event notifications directly to an email address, a syslog server, or a Simple Management Network Protocol (SNMP) traphost so that you are immediately notified of system issues that require prompt attention.

To monitor the most important activities in your system, you must monitor the important EMS events.

Because important event notifications are not enabled by default, you must configure the EMS to send notifications to either an email address, a syslog server, an SNMP traphost, or REST API server.

Configure EMS event notifications for important events if the following are true:

- You are implementing one of the following scenarios:
 - You are setting up a new system running ONTAP 9 that does not have EMS configured.
 - You have an existing system running ONTAP 9 that does not have EMS configured.
 - You are upgrading to ONTAP 9 that does not have EMS configured.
 - You have just completed a transition from Data ONTAP operating in 7-Mode to ONTAP 9.
- You want to use best practices, not explore every available option.
- You do not want to read a lot of conceptual background.

You can find the EMS Event Catalog under More Resources on this page: [ONTAP 9 Product Library](#). See [Convert the legacy event route-based routing to event notifications](#) for more information on how to perform the notification-based model conversion.

= Configure EMS event notifications and filters with System Manager

You can use System Manager to configure how the Event Management System (EMS) delivers event notifications so that you can be notified of system issues that require your prompt attention.

ONTAP version	With System Manager, you can...
ONTAP 9.10.1	Configure email addresses, syslog servers, and REST API clients (WebHooks), as well as SNMP traphosts.
ONTAP 9.7 to 9.10.0	Configure only SNMP traphosts. You can configure other EMS destination with the ONTAP CLI. See EMS configuration overview .

You can perform the following procedures:

- [\[add-ems-destination\]](#)
- [\[create-ems-filter\]](#)
- [\[edit-ems-destination\]](#)

- [edit-ems-filter]
- [delete-ems-destination]
- [delete-ems-filter]

Related information

- [EMS Event Catalog](#)
- [Using the CLI to configure SNMP traphosts to receive event notifications](#)

== Add an EMS event notification destination

You can use System Manager to specify to where you want EMS messages sent.

Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click  , then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Events Destinations** tab.
4. Click  **Add**.
5. Specify a name, an EMS destination type, and filters.

If needed, you can add a new filter. Click **Add a New Event Filter**.

6. Depending on the EMS destination type you selected, specify the following:

To configure...	Specify or select...
SNMP traphost	<ul style="list-style-type: none"> • Traphost name
Email (Beginning with 9.10.1)	<ul style="list-style-type: none"> • Destination email address • Mail server • From email address
Syslog server (Beginning with 9.10.1)	<ul style="list-style-type: none"> • Host name or IP address of the server
Webhook (Beginning with 9.10.1)	<ul style="list-style-type: none"> • Webhook URL • Client authentication (select this option to specify a client certificate)

== Create a new EMS event notification filter

Beginning with ONTAP 9.10.1, you can use System Manager to define new customized filters that specify the rules for handling EMS notifications.

Steps

1. Click **Cluster > Settings**.

2. In the **Notifications Management** section, click  , then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Event Filters** tab.
4. Click  .
5. Specify a name, and select whether you want to copy rules from an existing event filter or add new rules.
6. Depending on your choice, perform the following steps:

If you choose....	Then, perform these steps...
Copy rules from existing event filter	<ol style="list-style-type: none"> 1. Select an existing event filter. 2. Modify the existing rules. 3. Add other rules, if needed, by clicking .
Add new rules	Specify the type, name pattern, severities, and SNMP trap type for each new rule.

== Edit an EMS event notification destination

Beginning with ONTAP 9.10.1, you can use System Manager to change the event notification destination information.

Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click  , then click **View Event Destinations**.
3. On the **Notifications Management** page, select the **Events Destinations** tab.
4. Next to the name of the event destination, click  , then click **Edit**.
5. Modify the event destination information, then click **Save**.

== Edit an EMS event notification filter

Beginning with ONTAP 9.10.1, you can use System Manager to modify customized filters to change how event notifications are handled.

You cannot modify system-defined filters.

Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click  , then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Event Filters** tab.
4. Next to the name of the event filter, click  , then click **Edit**.
5. Modify the event filter information, then click **Save**.

== Delete an EMS event notification destination

Beginning with ONTAP 9.10.1, you can use System Manager to delete an EMS event notification destination.

You cannot delete SNMP destinations.

Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click , then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Events Destinations** tab.
4. Next to the name of the event destination, click , then click **Delete**.

== Delete an EMS event notification filter

Beginning with ONTAP 9.10.1, you can use System Manager to delete customized filters.

You cannot delete system-defined filters.

Steps

1. Click **Cluster > Settings**.
2. In the **Notifications Management** section, click , then click **View Event Destinations**.
3. On the **Notification Management** page, select the **Event Filters** tab.
4. Next to the name of the event filter, click , then click **Delete**.

= Configure EMS event notifications with the CLI

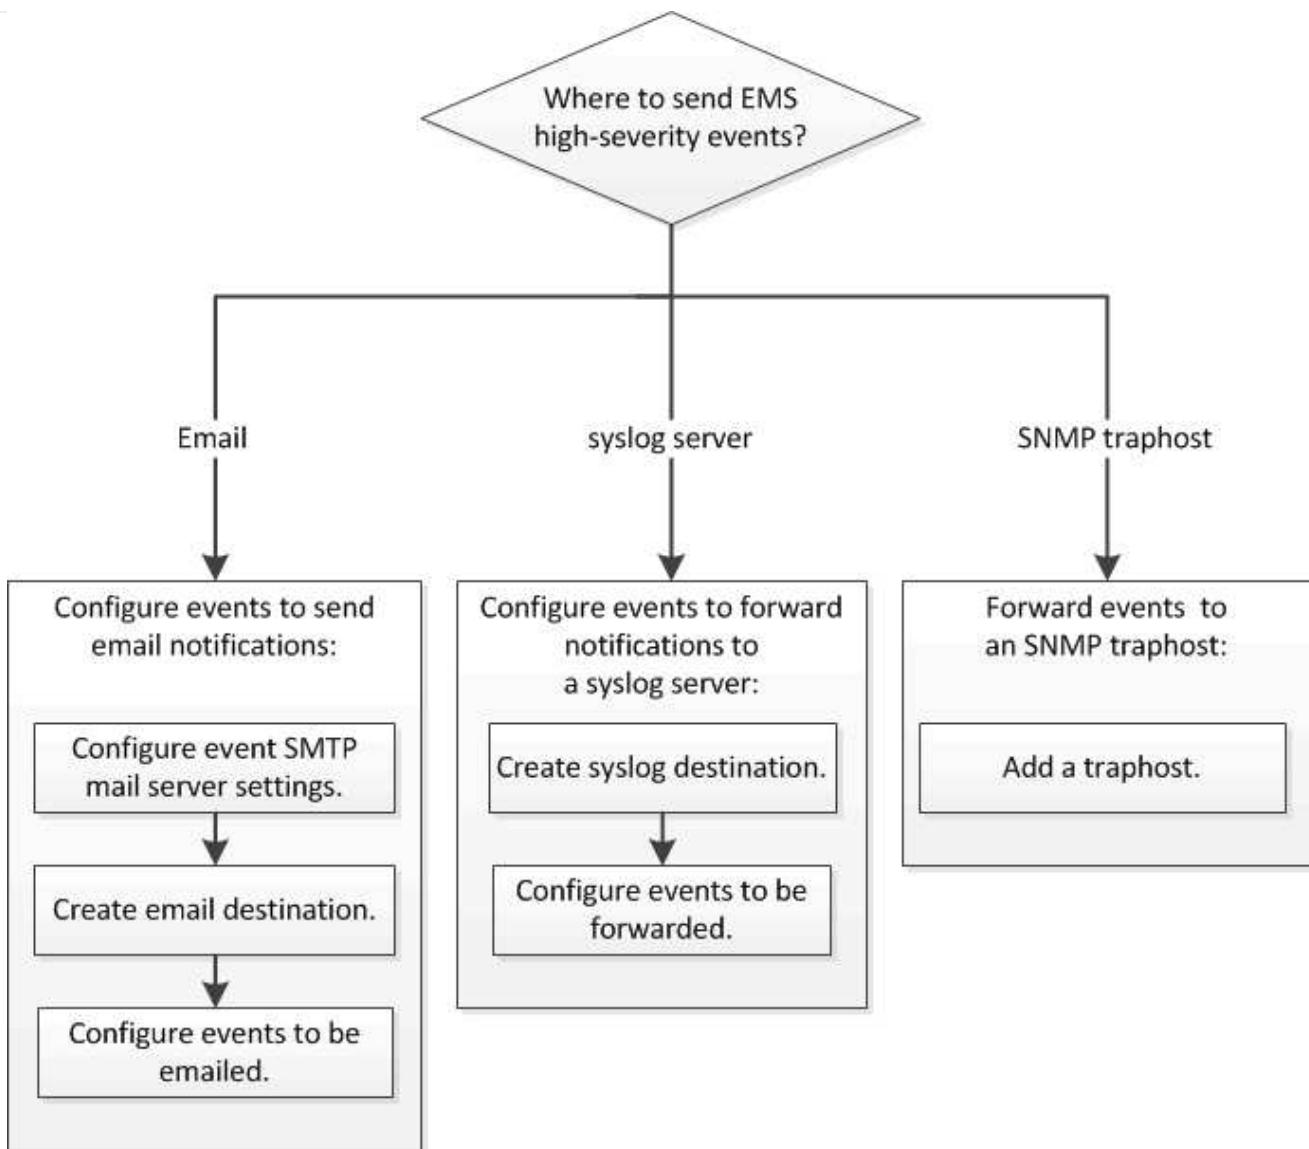

= EMS configuration workflow

:icons: font

:relative_path: ./error-messages/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.error-messages/..media/

You must configure important EMS event notifications to be sent either as email, forwarded to a syslog server, forwarded to an SNMP traphost, or forwarded to a REST API server. This helps you to avoid system disruptions by taking corrective actions in a timely manner.

= Decide where to send important event notifications

:icons: font

:relative_path: ./error-messages/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./error-messages../media/

Before you configure important EMS event notifications, you need to decide whether to send the notifications to an email address, a syslog server, an SNMP traphost, or REST API server.

About this task

If your environment already contains a syslog server for aggregating the logged events from other systems, such as servers and applications, then it is easier to use that syslog server also for important event notifications from storage systems.

If your environment does not already contain a syslog server, then it is easier to use email for important event notifications.

If you already forward event notifications to an SNMP traphost, then you might want to monitor that traphost for important events.

Choices

- Set EMS to send event notifications.

If you want...	Refer to this...
The EMS to send important event notifications to an email address	Configure important EMS events to send email notifications
The EMS to forward important event notifications to a syslog server	Configure important EMS events to forward notifications to a syslog server
If you want the EMS to forward event notifications to an SNMP traphost	Configure SNMP traphosts to receive event notifications
If you want the EMS to forward event notifications to a REST API server	Configure important EMS events to forward notifications to a REST API server

= Configure important EMS events to send email notifications

:icons: font

:relative_path: ./error-messages/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/.error-messages/..media/

To receive email notifications of the most important events, you must configure the EMS to send email messages for events that signal important activity.

What you'll need

DNS must be configured on the cluster to resolve the email addresses.

About this task

You can perform this task any time the cluster is running by entering the commands on the ONTAP command line.

Steps

1. Configure the event SMTP mail server settings:

```
event config modify -mail-server mailhost.your_domain -mail-from
cluster_admin@your_domain
```

2. Create an email destination for event notifications:

```
event notification destination create -name storage-admins -email
your_email@your_domain
```

3. Configure the important events to send email notifications:

```
event notification create -filter-name important-events -destinations
storage-admins
```

= Configuring important EMS events to forward notifications to a syslog server

:icons: font

```
:relative_path: ./error-messages/  
:imagesdir: /tmp/d20220215-32410-h8nxng/source/../error-messages/..media/
```

To log notifications of the most severe events on a syslog server, you must configure the EMS to forward notifications for events that signal important activity.

What you'll need

DNS must be configured on the cluster to resolve the syslog server name.

About this task

If your environment does not already contain a syslog server for event notifications, you must first create one. If your environment already contains a syslog server for logging events from other systems, then you might want to use that one for important event notifications.

You can perform this task any time the cluster is running by entering the commands on the ONTAP command line.

Steps

1. Create a syslog server destination for important events:

```
event notification destination create -name syslog-ems -syslog syslog-  
server-address
```

2. Configure the important events to forward notifications to the syslog server:

```
event notification create -filter-name important-events -destinations  
syslog-ems
```

= Configure SNMP traphosts to receive event notifications

:icons: font

:relative_path: ./error-messages/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../error-messages/..media/

To receive event notifications on an SNMP traphost, you must configure a traphost.

What you'll need

- SNMP and SNMP traps must be enabled on the cluster.

SNMP and SNMP traps are enabled by default.

- DNS must be configured on the cluster to resolve the traphost names.

About this task

If you do not already have an SNMP traphost configured to receive event notifications (SNMP traps), you must add one.

You can perform this task any time the cluster is running by entering the commands on the ONTAP command line.

Step

1. If your environment does not already have an SNMP traphost configured to receive event notifications, add one:

```
system snmp traphost add -peer-address snmp_traphost_name
```

All event notifications that are supported by SNMP by default are forwarded to the SNMP traphost.

= Configure important EMS events to forward notifications to a REST API server
:icons: font
:relative_path: ./error-messages/
:imagesdir: /tmp/d20220215-32410-h8nxng/source/.error-messages../media/

To receive event notifications on a REST API server, you must configure REST API webhook support.

Before you begin

- You need a server with REST API/webhook support capable of receiving EMS events.
- The REST API server can utilize server-side or client-side security certificates.
- Configuration for certificates is determined by destination. Refer to the following for an overview of certificate configuration based on destination:
 - **http:** - No certificate involved
 - **https:** - The server certificate is verified by the ONTAP system. Optionally, a client certificate can be configured that will be sent by the ONTAP system for the server to verify.
- Client-side certificates require both the private key and certificate available for installation on the source ONTAP system(s).

If you are configuring both a client and server certificate REST API forward, a server-side certificate is required to utilize a client-side certificate. As a result, you must follow the client-side instructions to use both methods of authentication.

== Configuring a HTTP Rest API forward

About this task

You can perform this task any time the cluster is running by entering the commands on the ONTAP command line.

Steps

1. Create a new destination `restapi-ems` destination for the filter `important-events`:

```
event notification destination create -name restapi-ems -rest-api-url  
http://<url_to_rest_api_server>
```

2. Create the notification that links the `important-events` filter with the new `restapi-ems` destination:

```
event notification create -filter-name important-events -destinations  
restapi-ems
```

== Configuring a server certificate HTTPS Rest API forward

About this task

This procedure assumes you have previously generated a server-side private key and public certificate. It

also assumes you have the root certificate available to install in ONTAP.

Steps

1. Install the appropriate server private key and public certificates in your REST API server.

Specific instructions depend on the server.

2. Install the server root certificate in ONTAP.

```
security certificate install -type server-ca
```

The command will query for the public certificate.

3. Create the `restapi-ems` destination for the filter `important-events`.

You must use the HTTPS scheme for the server-side certificate to be utilized.

```
event notification destination create -name restapi-ems -rest-api-url  
https://<url_to_rest_api_server>
```

4. Create the notification that links the `important-events` filter with the new `restapi-ems` destination:

```
event notification create -filter-name important-events -destinations  
restapi-ems
```

== Configuring a client certificate HTTPS Rest API forward

About this task

The usage of a client certificate is optional and only necessary if client authentication by the server is desired. This procedure assumes you have previously generated a client private key and public certificate.

Steps

1. Install the appropriate root and intermediate certificates, in the Rest API server, to validate your client certificate.

2. Install the client certificate in ONTAP.

```
security certificate install -type client
```

The command will query for the private key and the public certificate.

3. Create the `restapi-ems` destination for the filter `important-events`.

```
<code>event notification destination create -name restapi-ems -rest-api-url <a  
href="https://<url_to_rest_api_server>" class="bare">https://<url_to_rest_api_server></a>;  
-certificate-authority &lt;issuer of the client certificate&gt; -certificate-serial &lt;serial of the client  
certificate&gt;</code>
```

4. Create the notification that links the `important-events` filter with the new `restapi-ems` destination.

```
event notification create -filter-name important-events -destinations  
restapi-ems
```

= Update deprecated EMS event mapping

= EMS event mapping models

:icons: font

:relative_path: ./error-messages/

:imagesdir: /tmp/d20220215-32410-h8nxng/source./error-messages../media/

Prior to ONTAP 9.0, EMS events could only be mapped to event destinations based on event name pattern matching. The ONTAP command sets (`event destination`, `event route`) that use this model continue to be available in the latest versions of ONTAP, but they have been deprecated starting with ONTAP 9.0.

Beginning with ONTAP 9.0, the best practice for ONTAP EMS event destination mapping is to use the more scalable event filter model in which pattern matching is done on multiple fields, using the `event filter`, `event notification`, and `event notification destination` command sets.

If your EMS mapping is configured using the deprecated commands, you should update your mapping to use the `event filter`, `event notification`, and `event notification destination` command sets.

There are two types of event destinations:

1. System-generated destinations: There are five system-generated event destinations (created by default)

- allevents
- asup
- criticals
- pager
- traphost

Some of the system-generated destinations are for special purpose. For example, the asup destination routes callhome.* events to the AutoSupport module in ONTAP to generate AutoSupport messages.

2. User-created destinations: These are manually created using the `event destination create` command.

```

cluster-1::event*> destination show

Hide
Name          Mail Dest.        SNMP Dest.        Syslog Dest.

```

In the deprecated model, EMS events are individually mapped to a destination using the `event route add-destinations` command.

```
cluster-1::event*> route add-destinations -message-name raid.aggr.*  
-destinations test  
This command is deprecated. Use the "event filter", "event notification  
destination" and "event notification" commands, instead.  
4 entries were acted on.
```

```
cluster-1::event> route show -message-name raid.aggr.*
```

Time	Message	Severity	Destinations	Threshd	Freq
	raid.aggr.autoGrow.abort	NOTICE	test	0	
0	raid.aggr.autoGrow.success	NOTICE	test	0	
0	raid.aggr.lock.conflict	INFORMATIONAL	test	0	
0	raid.aggr.log.CP.count	DEBUG	test	0	
0					
4	entries were displayed.				

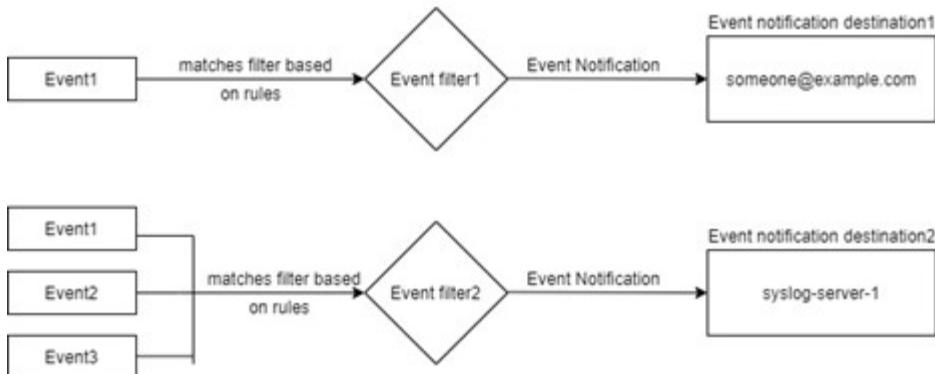

The new, more scalable EMS event notifications mechanism is based on event filters and event notification destinations. Refer to the following KB article for detailed information on the new event notification mechanism:

- Overview of Event Management System for ONTAP 9

Legacy routing based model

Event notification based model

= Update EMS event mapping from deprecated ONTAP commands

:icons: font

:relative_path: ./error-messages/

:imagesdir: /tmp/d20220215-32410-h8nxng/source/../error-messages/..../media/

If your EMS event mapping is currently configured using the deprecated ONTAP command sets (event destination, event route), you should follow this procedure to update your mapping to use the event filter, event notification, and event notification destination command sets.

Steps

1. List all the event destinations in the system using the `event destination show` command.

```

cluster-1::event*> destination show

Hide
Name          Mail Dest.      SNMP Dest.      Syslog Dest.
Params

-----
-----
allevents     -
false
asup          -
false
criticals    -
false
pager         -
false
test          test@xyz.com   -
false
traphost     -
false
6 entries were displayed.

```

- For each destination, list the events being mapped to it using the `event route show -destinations <destination name>` command.

```

cluster-1::event*> route show -destinations test
                                         Freq
Time
Message           Severity      Destinations
Threshd Threshd
-----
-----
raid.aggr.autoGrow.abort    NOTICE       test      0
0
raid.aggr.autoGrow.success NOTICE       test      0
0
raid.aggr.lock.conflict    INFORMATIONAL test      0
0
raid.aggr.log.CP.count     DEBUG        test      0
0
4 entries were displayed.

```

- Create a corresponding event filter which includes all these subsets of events. For example, if you want to include only the `raid.aggr.*` events, use a wildcard for the `message-name` parameter when creating the filter. You can also create filters for single events.

You can create up to 50 event filters.

```
cluster-1::event*> filter create -filter-name test_events

cluster-1::event*> filter rule add -filter-name test_events -type
include -message-name raid.aggr./*

cluster-1::event*> filter show -filter-name test_events
Filter Name Rule      Rule      Message Name      SNMP Trap Type
Severity
Position Type
-----
-----
test_events
    1      include    raid.aggr.*      *
*
    2      exclude    *      *
*
2 entries were displayed.
```

4. Create an event notification destination for each of the event destination endpoints (i.e., SMTP/SNMP/syslog)

```
cluster-1::event*> notification destination create -name dest1
-email test@xyz.com

cluster-1::event*> notification destination show
Name      Type      Destination
-----
dest1      email      test@xyz.com (via "localhost" from
"admin@localhost", configured in "event config")
snmp-traphost  snmp      - (from "system snmp traphost")
2 entries were displayed.
```

5. Create an event notification by mapping the event filter to the event notification destination.

```

cluster-1::event*> notification create -filter-name asup_events
-destinations dest1

cluster-1::event*> notification show
ID      Filter Name          Destinations
-----  -----
1      default-trap-events  snmp-traphost
2      asup_events           dest1
2 entries were displayed.

```

6. Repeat steps 1-5 for each event destination that has an event route mapping.

Events routed to SNMP destinations should be mapped to the snmp-traphost event notification destination. The SNMP traphost destination uses the system configured SNMP traphost.

```

cluster-1::event*> system snmp traphost add 10.234.166.135

cluster-1::event*> system snmp traphost show
      scspr2410142014.gdl.englab.netapp.com
(scsp2410142014.gdl.englab.netapp.com) <10.234.166.135>
Community: public

cluster-1::event*> notification destination show -name snmp-traphost

      Destination Name: snmp-traphost
      Type of Destination: snmp
      Destination: 10.234.166.135 (from "system snmp
traphost")
      Server CA Certificates Present?: -
      Client Certificate Issuing CA: -
      Client Certificate Serial Number: -
      Client Certificate Valid?: -

```
